
THE COMPLETE ENCYCLOPEDIC GUIDE TO ASTROLOGY

Preface:

This encyclopedia is a comprehensive work on astrology, exceeding 2,500 pages (approximately 2,700 pages). In it, I have carefully selected foundational and authoritative texts in the field of astrology.

The reason I present this discipline is that most available sources on astrology are misleading; approximately 95% of online content focuses on prediction and foretelling the future. In reality, astrology was originally developed by the sages of ancient civilizations to help individuals understand the self and the inner nature—not to attempt to uncover the unseen.

This work is intended for those who wish to study astrology in depth without getting lost among countless scattered books. There are more than 300 astrology books available online, yet I have selected only about seven that are sufficient and comprehensive—this selection being the result of six continuous years of study and reading in this field.

I emphasize again: this discipline was established by the wise men of ancient civilizations, such as the Greek, Vedic, and Babylonian traditions, to facilitate self-understanding, not to predict the unseen.

Finally, this book is written in English. Those who wish to benefit from it may rely on machine translation if they are not proficient in the English language.

And with that, I place my trust in God, and through Him comes success.

OF AN

ANTIQUATED SCIENCE

ADVERTISEMENT

The use recently made of Astrology in the poetical machinery of certain works of genius (which are of the highest popularity, and above all praise), seems to have excited in the world at large a desire to learn something of the mysteries of that science which has, in all former ages, if not in these days, more or less engaged reverence and usurped belief. The apparent existence of such a general desire has caused the completion of the following Translation, and its presentation to the public; although it was originally undertaken only in part, and merely to satisfy two or three individuals of the

zaid n. adwan

grounds on which the now neglected doctrines of Astrology had so long and so fully maintained credit.

PREFACE

Of all sciences, whether true or false, which have at any time engaged the attention of the world, there is not one of which the real or assumed principles are less generally known, in the present age, than those of Astrology. The whole doctrine of this science is commonly understood to have been completely overturned; and, of late, people seem to have satisfied themselves with merely knowing the import of its name. Such contented ignorance, in persons, too, sufficiently informed in other respects, is the more extraordinary, since Astrology has sustained a most conspicuous part throughout the history of the world, even until days comparatively recent. In the East, where it first [Pg xii]arose, at a period of very remote antiquity,[1] and whence it came to subjugate the intellect of Europe, it still even now holds sway. In Europe, and in every part of the world where learning had "impress'd the human soil," Astrology reigned supreme until

zaid n. adwan

the middle of the 17th century. It entered into the councils of princes, it guided the policy of nations, and ruled the daily actions [Pg xiii]of individuals. All this is attested by the records of every nation which has a history, and by none more fully than by those of England. Yet, with these striking facts before their eyes, the present generation seem never, until now, to have inquired on what basis this belief of their forefathers was established, nor by what authority the delusion (if it was one) could have been for so many ages supported. Among a thousand persons who now treat the mention of Astrology with supercilious ridicule, there is scarcely one who knows distinctly what it is he laughs at, or on what plea his ancestors should stand excused for having, in their day, contemplated with respect the unfortunate object of modern derision.[Pg xiv]

The general want of information on these points, and the indifference with which such want has been hitherto regarded, cannot surely be attributed solely to the modern disrepute of the science; for mankind have usually, in every successive age, exercised great industry in tracing all previous customs, however trifling or obsolete, and in examining all sorts of creeds, however unimportant or erroneous, whenever there has appeared any striking connection between such matters and historical facts; and, since astrology is most unquestionably blended intimately with history, it therefore becomes necessary to seek for some further hypothesis, by which this ignorance and indifference may be accounted for.

Perhaps astrology has been conceived to have borne the same relation to astronomy as alchymy did to chymistry. If such has been the notion, it has certainly been adopted in error, for a modern chymist is still almost an alchymist: it is true that he no longer delays his work in deference to the planets, nor does he now try to make gold, nor to distil elixir of earthly immortality; but nevertheless he still avails himself, to a certain degree, of the same rules and the same means as those of the old alchymist: he is still intent upon the subtle processes of Nature, and still imitates her as far as he can. He reduces the diamond to charcoal by an operation analogous to that by which the

zaidn.adwan

alchymist sought to transmute lead into gold; and he mainly differs from the alchymist only in having assured himself that there is a point beyond which Nature forbids facsimiles. Not so slightly, however, does the astronomer differ from the astrologer, but *toto cælo*: the astrologer considered the heavenly bodies and their motions merely as the mechanism wherewith he was to weave the tissue of his predictions; and astronomy is no more an integral part of astrology, than the loom is of the web which has been woven by it. To have an idea of what alchymy was, it is sufficient to have an idea of chymistry; but astronomy, in itself, will never give a notion of astrology, which requires additional and distinct consideration.

It may be urged, that in the present day a general idea of this bygone and disused science is quite sufficient for everybody not professedly antiquarian. Such an assertion would doubtless never be controverted, provided the proposed general idea might comprehend the truth. But the present actual general idea of astrology is by no means so comprehensive; indeed, nothing can well be more inaccurate, or even more false: it seems to have been adopted not from the elements of the science itself, but from trite observations made by writers against the science; and consequently the world now wonders at the lamentable defect of understanding that could ever have permitted belief in it—forgetting that astrology has been consigned to neglect, not in consequence of any *primâ facie* palpability in its imputed fallacies, nor indeed of any special skill or acuteness on the part of its professed adversaries, but rather in consequence of the sudden and astonishing growth of other undoubted sciences, with which it has been [Pg xv]presumed to be incompatible, and which during the thousands of years of the reign of astrology were either unborn, or still slumbering in continued infancy.[2]

The words “professed adversaries,” which have just now been used, are of course not intended to be applied to those mighty explorers of Nature’s laws and man’s powers, who, in their lofty career, may have made an incidental swoop at the pretensions of astrology. Directly engaged in more exact pursuits, they stopped not to dissect this their

casual prey, which, after having been thus struck by eagles, was left to regale crows and daws, and these, in their convivial loquacity, accused their unfortunate victims of crimes incapable of being committed, and of offences which had never been imagined. Of the real faults of their victim these garrulous bipeds seem not to have been aware, or, if aware, they seem to have considered them as not sufficiently prominent. Nor was this want of candour or information absolutely confined to the mere vulgar herd of vituperative scribblers, for even the sparkling essay against astrology, written by Voltaire (in his irrepressible desire to convince the world that he was *au fait* in everything), proves only that the writer, though the most generally informed man of his time, had mistaken the really assailable points of the object of his attack.

The author of the present Translation has no intention now of either advocating or impugning the doctrines of the science of which his Translation discourses: his purpose is a different one. He has that sort of respect for "the dead, which are really dead," which, although it does not incline him to "praise" them "*more* than the living, which are yet alive," is still sufficient to incite him to endeavour to avert the imputation of idiot credulity, to which their faith in astrology seems now to subject them in the general opinion of the enlightened "living." And, while he disclaims all idea of presuming to offer any argument on either side of the question, as to the validity [Pg xvi]of the science, he must still, at the same time, confess his admiration of the ingenuity and contrivance manifest in its construction, and avow his readiness to believe that all its harmonized complications might have easily held dominion over some of the strongest minds in that darker period when it flourished.

In executing here the desire of attempting to vindicate the ancient credence in astrology, an elaborate disquisition would surely be not only unnecessary, but misplaced: it seems sufficient to refer the reader to the work of which the following is a translation, and to these undisputed facts—that the science was formerly inculcated by the highest and most erudite authorities of the period—that it was insisted on by

votaries in all parts of the world, attesting and producing instances of its truth;—and, moreover, that it was so finely and beautifully put together, as to cause the only deficiency of one small, though most important, link in its whole chain of argument, to be undetected by dull minds, and readily supplied by enthusiastic genius. For centuries after centuries all branches of learning were either made subservient to astrology, or carried on in close alliance with it; and many of the illustrious names which it recalls to our recollection are gratefully reverenced even by modern science. The genius of Roger Bacon, although he was the first of that school of natural philosophy which acknowledges none but experimented truths, was nevertheless bowed to the doctrines of judicial astrology; and his greater Namesake, who after an interval of several centuries succeeded to him in giving proper direction to the mental energy, was still an arguer in favour of celestial influences: it may be, therefore, fairly inferred, that the subtle spell which had strength to enthrall "stuff" so "stern," could have been of no weak or vulgar order, but that it was sufficiently potent and refined to interest and amuse even the present age.[3]

[Pg xvii]In this little volume will be found the whole of the elements of astrology, and the entire ground-work of those stupendous tomes in folio and quarto on the same subject, which were produced in myriads during the 16th and 17th centuries, for the due mystification of the then world. The present volume is addressed equally to the general reader, as well as to the votary of pure astrology, if any such there be; to the one it offers amusement; for the other, it should contain the most glowing interest. Even to the speculative metaphysician it will furnish food for contemplation; for, in addition to its peculiar hypothesis of cause and effect, it develops many of those apparent incongruities of character so often united in the same individual; and this development, even although adapted to the doctrine of the stars, still merits attention; inasmuch as the phenomena of which it treats (in whatever way they may be produced or regulated) will ever remain in actual existence.

The only English translation of Ptolemy's Tetrabiblos, hitherto published, appears to have been first set forth in 1701, under the name of "The Quadripartite." That publication has been long removed from general sale; and its gross misinterpretation of the author, caused by the carelessness or ignorance of Whalley and his assistants, by whom it was produced, has rendered most of its pages unintelligible: its absence is, therefore, scarcely to be regretted. The second edition of the same translation, professing to be "revised, corrected, and improved," and published by Browne and Sibley, in 1786, was not, in any one instance, purified from the blunders and obscurities which disgraced its predecessor: it seems, in fact, less excusable than the former edition, of which it was merely a reprint, without being at all corrected, not even in certain typographical *errata* which the former printer had been zealous enough to point out in his final page. Even this second publication, worthless as it intrinsically is, can rarely now be met with, and, like the former, only at a very heavy price.

The present Translation has been made from Proclus's Greek Paraphrase of Ptolemy's original text; the edition followed is that of the Elzevirs, dated in 1635.[4] But, in the course of translation, continual references have been also had to various editions of the original text, in order to ascertain the proper acceptation of doubtful passages. The editions thus inspected were that by Camerarius, printed at Nuremberg in 1535; that by Melancthon, printed at Basle in 1553; and that by Junctinus, printed, with his own enormous commentaries, at Lyons, in 1581. Independently of [Pg xviii]these references, the present translation has been collated with the Latin of Leo Allatius, and with two other Latin translations: one printed at Basle, together with a translation of the Almagest in 1541; the other by itself at Perugio, in 1646.[5] The Translator has devoted all this extreme care and attention to his labours, in the wish to render Ptolemy's astro-judicial doctrine [Pg xix]into English as purely and perfectly as possible; and, with the same view, he has likewise added, in an Appendix, certain extracts from such parts of the Almagest as were found to be referred to in his present work. Further illustration is

also given by notes gathered from the "Primum Mobile" of Placidus,[6] and from a variety of other sources whence any elucidation of the text might be derived. Even Whalley's "Annotations" (to use his own grandiloquent designation) have occasionally yielded information, not altogether unimportant, although generally incomplete.

It seems improper to close this Preface (notwithstanding the bulk it has already attained), without annexing the following short notice of the life and works of the great man from whom the Tetrabiblos has emanated.[Pg xx]

Claudius Ptolemy was born at Pelusium, in Ægypt, and became an illustrious disciple of the school of Alexandria, in which city he flourished during the reign of Adrian and that of Antoninus Pius. The date of his birth has been commonly assigned to the 70th year of the Christian æra; but the accuracy of this date seems questionable; for he has himself noted in one part of his works, that Antoninus reigned twenty-three years. He must have, therefore, survived that prince; and, as it is not probable that he continued his scientific labours until after ninety years of age, which he must have done had he been born about the year 70, because Antoninus died in the year 161, it seems that his birth would be more properly ascribed to some later period. Moreover, it is asserted by the Arabians, that he died in the 78th year of his age; and a similar statement is also made by Luca Gauricus, in the dedication of his version of the Almagest[7] to Dominico Palavicini: Gauricus has, however, placed his death in the year 147, which does not accord with the fact of his having survived Antoninus.

Ptolemy has recorded that he observed, at Alexandria, an eclipse of the Moon, in the 9th year of Adrian; and that he made many observations upon the fixed stars in the 2nd year of Antoninus Pius: whence it may be concluded, that his observations upon the heavens were principally made during the period from A.D. 125 to A.D. 140, or thereabouts; and it also follows, of course, that the supposition, entertained by some authors, of his identity with the Ptolemy who was always in attendance upon Galba, as his personal astrologer, and who promised Otho that he should survive Nero and obtain

the empire, is entirely without foundation. To Gauricus's[8] version of the Almagest there is also another dedication, addressed to Pope Sixtus, and composed by George Trapezuntius, describing Ptolemy as "*regiâ stirpe oriundum*," and explaining that he had, "with a truly regal mind," applied himself to the sciences, because the ancient sceptre of the Ptolemies had previously passed into the hands of Cleopatra, and because the kingdom of Ægypt had been since reduced to the state of a Roman province. The authentic details of the circumstances of Ptolemy's life are, however, extremely few. It is said that he was distinguished among the Greeks by the epithets "most wise," and "most divine," on account of his great learning; and, according to the Preface to Whalley's translation of the Tetrabiblos, the Arabians report that "he was extremely abstemious, and rode much on horseback"; adding, that although he was "spruce in apparel," yet his breath was not remarkable for an agreeable odour.

The errors of the Ptolemaic theory of the universe have now been long discarded; but there are many points in which modern sciences, and modern astronomy in particular, have reaped incalculable benefits from the labours and researches of its great founder. He has preserved and [Pg xxi]transmitted to us the observations and principal discoveries of remoter periods, and has enriched and augmented them with his own. He corrected Hipparchus's catalogue of the fixed stars, and formed tables for the calculation and regulation of the motions of the Sun, Moon, and planets. He was, in fact, the first who collected the scattered and detached observations of Aristotle, Hipparchus, Posidonius, and others on the economy of the world, and digested them into a system, which he set forth in his Μεγαλη Σνταξις or Great Construction, divided into thirteen books, and called, after him, the Ptolemaic System. This and all his other astronomical works are founded upon the hypothesis, that the earth is at rest in the centre of the universe, and that the heavenly bodies, stars, and planets, all move round it in solid orbs, whose motions are all directed by one *primum mobile*, or first mover, of which he discourses at large in the "Great Construction." In that work he also treats of

the figure and divisions of the earth, of the right and oblique ascensions of the heavenly bodies, and of the motions of the Sun, Moon, and planets; and he gives tables for finding their situations, latitudes, longitudes, and motions: he treats also of eclipses, and the methods of computing them; and he discourses of the fixed stars, of which he furnishes a numerous catalogue, with their magnitudes, latitudes, and longitudes.[9]

It has been truly said, that "Ptolemy's order, false as it was, enabled observers to give a plausible account of the motions of the Sun and Moon, to foretell eclipses, and to improve geography[10];" or, in other words, that it represented the actual phenomena of the heavens as they really appear to a spectator on the earth. It is therefore clear [Pg xxii]that Ptolemy's astrology is just as applicable to modern and improved astronomy as it was to his own.[11]

In the year 827[12] the "Great Construction" was translated by the Arabians into their own language, and by them communicated to Europe. It is through them that it has been usually known by the name of the Almagest. In the 13th century, the Emperor Frederic II caused it to be translated from the Arabic into Latin, and Sacrobosco[13] was consequently enabled to write his famous work upon the sphere. It was not, however, until about the end of the 15th century that the "Great Construction" was translated into Latin from the *original* text; and this important service was rendered to science by Purbach, a professor of philosophy at Vienna, who learned the Greek tongue at the instigation of Cardinal Bessarion. By means of this translation, the Ephemerides of George Müller, surnamed Regiomontanus, a disciple of Purbach's, were first composed. The Greek text of the Almagest, or Great Construction, was first published at Basle, by Simon Grynæus, in 1538; and it was again printed at the same place in 1551, with certain other works of Ptolemy.[14] The rest of Ptolemy's works connected with astronomy, and now extant, are the Tetrabiblos, or Four Books of the Influence of the Stars[15] (now translated); the Centiloquy, or Fruit of his Four Books, being a kind of supplement to the former; and the Significations of the Fixed Stars. The last is merely

a daily calendar, showing the risings and settings of the stars, and the nature of the weather thereby produced. There are likewise extant his geographical work (which has rendered important service to modern geographers), and also his celebrated book on Harmonics, or the Theory of Sound.

[Pg xxiii]Proclus, to whom the world is indebted for the improved text of the Tetrabiblos,[16] was born at Constantinople, in the year 410. He studied [Pg xxiv]at Alexandria and at Athens, and became very eminent among the later Platonists. He succeeded Syrianus, a celebrated philosopher, in the rectorship of the Platonic school at Athens, and died there in 485.[17] He was a most voluminous author, in poetry as well as in prose. Among his works there are Hymns to the Sun, to Venus, and to the Muses; Commentaries upon several pieces of Plato, and upon Ptolemy's Tetrabiblos[18]; an Epitome or Commendium of all the Astronomical Precepts demonstrated in the Almagest; and elements of Theology and Natural Philosophy. He was in dispute with the Christians on the question of the eternity of the world, which he undertook to prove in eighteen elaborate arguments. A late writer in a certain periodical work has erroneously identified him with another Proclus, who was in favour with the Emperor Anastasius, and who destroyed the ships of Vitalianus, when besieging Constantinople in 514, by burning them with great brazen mirrors, or *specula*.

PTOLEMY'S TETRABIBLOS

OR

FOUR BOOKS

OF THE

INFLUENCE OF THE STARS

BOOK THE FIRST

CHAPTER I

PROEM

The studies preliminary to astronomical prognostication, O Syrus! are two: the one, first alike in order and in power, leads to the knowledge of the figurations of the Sun, the Moon, and the stars; and of their relative aspects to each other, and to the earth: the other takes into consideration the changes which their aspects create, by means of their natural properties, in objects under their influence.

zaid n adwan

The first mentioned study has been already explained in the Syntaxis[19] to the utmost practicable extent; for it is complete in itself, and of essential utility even without being blended with the second; to which this treatise will be devoted, and which is not equally self-complete. The present work shall, however, be regulated by that due regard for truth which philosophy demands: and since the material quality of the objects acted upon renders them weak and variable, and difficult to be accurately apprehended, no positive or infallible rules (as were given in detailing the first doctrine, which is always governed by the same immutable laws) can be here set forth: while, on the other hand, a due observation of most of those general events, which evidently trace their causes to the Ambient, shall not be omitted.

It is, however, a common practice with the vulgar to slander everything which is difficult of attainment, and surely they who condemn the first of these two studies must be considered totally blind, whatever arguments may be produced in support of those who impugn the second. [Pg 2]There are also persons who imagine that whatever they themselves have not been able to acquire, must be utterly beyond the reach of all understanding; while others again will consider as useless any science of which (although they may have been often instructed in it) they have failed to preserve the recollection, owing to its difficulty of retention. In reference to these opinions, therefore, an endeavour shall be made to investigate the extent to which prognostication by astronomy is practicable, as well as serviceable, previously to detailing the particulars of the doctrine.

CHAPTER II

KNOWLEDGE MAY BE ACQUIRED BY
ASTRONOMY TO A CERTAIN EXTENT

zaid n. adwan

That a certain power, derived from the æthereal nature, is diffused over and pervades the whole atmosphere of the earth, is clearly evident to all men. Fire and air, the first of the sublunary elements, are encompassed and altered by the motions of the æther. These elements in their turn encompass all inferior matter, and vary it as they themselves are varied; acting on earth and water, on plants and animals.[20]

[Pg 3]The Sun, always acting in connection with the Ambient, contributes to the regulation of all earthly things: not only by the revolution of the seasons does he bring to perfection the embryo of animals, the buds of plants, the spring of waters, and the alteration of bodies, but by his daily progress also he operates other changes in light, heat, moisture, dryness and cold; dependent upon his situation with regard to the zenith.

The Moon, being of all the heavenly bodies the nearest to the Earth, also dispenses much influence; and things animate and inanimate sympathize and vary with her. By the changes of her illumination, rivers swell and are reduced; the tides of the sea are ruled by her risings and settings; and plants and animals are expanded or collapsed, if not entirely at least partially, as she waxes or wanes.

The stars likewise (as well the fixed stars as the planets), in performing their revolutions,[21] produce many impressions on the Ambient. They cause heats, winds, and storms, to the influence of which earthly things are conformably subjected.

And, further, the mutual configurations of all these heavenly bodies, by commingling the influence with which each is separately invested, produce a multiplicity of changes. The power of the Sun however predominates, because it is more generally distributed; the others either co-operate with his power or diminish its effect: the Moon more frequently and more plainly performs this at her conjunction, at her first and last quarter, and at her opposition: the stars act also to a similar purpose, but at longer intervals and more obscurely than the Moon; and their operation principally depends upon the mode of their visibility, their occultation and their declination.

Zain Adwan

From these premises it follows not only that all bodies, which may be already compounded, are subjected to the motion of the stars, but also that the impregnation and growth of the seeds from which all bodies proceed, are framed and moulded by the quality existing in the Ambient at the time of such impregnation and growth. And it is upon this principle that the more observant husbandmen and shepherds are accustomed, by drawing their inferences from the particular breezes which may happen at seed-time and at the impregnation of their cattle, to form predictions as to the quality of the expected produce. In short, however unlearned in the philosophy of nature, these men can foretell, solely by their previous observation, all the more general [Pg 4]and usual effects which result from the plainer and more visible configurations of the Sun, Moon, and stars. It is daily seen that even most illiterate persons, with no other aid than their own experienced observation, are capable of predicting events which may be consequent on the more extended influence of the Sun and the more simple order of the Ambient, and which may not be open to variation by any complex configurations of the Moon and stars towards the Sun. There are, moreover, among the brute creation, animals who evidently form prognostication, and use this wonderful instinct at the changes of the several seasons of the year, spring, summer, autumn, and winter; and, also, at the changes of the wind.

In producing the changes of the seasons, the Sun itself is chiefly the operating and visible cause. There are, however, other events which, although they are not indicated in so simple a manner, but dependent on a slight complication of causes in the Ambient, are also foreknown by persons who have applied their observation to that end. Of this kind, are tempests and gales of wind, produced by certain aspects of the Moon, or the fixed stars, towards the Sun, according to their several courses, and the approach of which is usually foreseen by mariners. At the same time, prognostication made by persons of this class must be frequently fallacious, owing to their deficiency in science and their consequent inability to give necessary consideration to the time and place, or

to the revolutions of the planets; all which circumstances, when exactly defined and understood, certainly tend towards accurate foreknowledge.

When, therefore, a thorough knowledge of the motions of the stars, and of the Sun and Moon, shall have been acquired, and when the situation of the place, the time, and all the configurations actually existing at that place and time, shall also be duly known; and such knowledge be yet further improved by an acquaintance with the natures of the heavenly bodies—not of what they are composed, but of the effective influences they possess; as, for instance, that heat is the property of the Sun, and moisture of the Moon, and that other peculiar properties respectively appertain to the rest of them;—when all these qualifications for prescience may be possessed by any individual, there seems no obstacle to deprive him of the insight, offered at once by nature and his own judgment, into the effects arising out of the quality of all the various influences compounded together. So that he will thus be competent to predict the peculiar constitution of the atmosphere in every season, as, for instance, with regard to its greater heat or moisture, or other similar qualities; all which may be foreseen by the visible position or configuration of the stars and the Moon towards the Sun.

Since it is thus clearly practicable, by an accurate knowledge of the points above enumerated, to make predictions concerning the proper quality of the seasons, there also seems no impediment to the formation of similar prognostication concerning the destiny and disposition of every human being. For by the constitution of the Ambient, even at the [Pg 5]time of any individual's primary conformation, the general quality of that individual's temperament may be perceived; and the corporeal shape and mental capacity with which the person will be endowed at birth may be pronounced; as well as the favourable and unfavourable events indicated by the state of the Ambient, and liable to attend the individual at certain future periods; since, for instance, an event dependent on one disposition of the Ambient will be advantageous to a particular temperament,

zain.adwan

and that resulting from another unfavourable and injurious. From these circumstances, and others of similar import, the possibility of prescience is certainly evident.

There are, however, some plausible assailants of this doctrine, whose attacks although greatly misapplied seem yet worthy of the following observations.

In the first place, the science demands the greatest study and a constant attention to a multitude of different points; and as all persons who are but imperfectly practised in it must necessarily commit frequent mistakes, it has been supposed that even such events as have been truly predicted have taken place by chance only, and not from any operative cause in nature. But it should be remembered that these mistakes arise, not from any deficiency or want of power in the science itself, but from the incompetency of unqualified persons who pretend to exercise it. And, besides this, the majority of the persons who set themselves up as professors of this science, avail themselves of its name and credit for the sake of passing off some other mode of divination; by that means defrauding the ignorant, and pretending to foretell many things which from their nature cannot possibly be foreknown; and consequently affording opportunities to more intelligent people to impugn the value even of such predictions as can rationally be made. The reproach, however, thus brought upon the science is wholly unmerited; for it would be equally just to condemn all other branches of philosophy, because each numbers among its professors some mischievous pretenders.

Secondly, it is not attempted to be denied that any individual, although he may have attained to the greatest possible accuracy in the science, must still be liable to frequent error, arising out of the very nature of his undertaking, and from the weakness of his limited capacity in comparison with the magnitude of his object. For the whole theory of the quality of matter is supported by inference rather than by positive and scientific proof; and this is caused principally by the concretion of its temperament out of a multitude of dissimilar ingredients. And, although the former configurations of the planets have been observed to produce certain consequences (which have been adapted

to configurations now taking place), and are, after long periods, and in a greater or less degree, resembled by subsequent configurations, yet these subsequent configurations never become exactly similar to those which have preceded them. For an entire return [Pg 6]of all the heavenly bodies to the exact situation in which they have once stood with regard to the earth will never take place, or at least not in any period determinable by human calculation, whatever vain attempts may be made to acquire such unattainable knowledge.[22] The examples referred to for guidance being therefore not exactly similar to the existing cases to which they are now applied, it must naturally follow that predictions are sometimes not borne out by the events. Hence arises the sole difficulty in the consideration of events produced by the Ambient. For no other concurrent cause has been hitherto combined with the motion of the heavenly bodies; although the doctrine of nativities, particularly that part of it relating to peculiar individual temperament, demands also the consideration of other concomitant causes, which are neither trifling nor unimportant, but essentially potent in affecting the individual properties of the creatures born. Thus the variety in seed has the chief influence in supplying the peculiar quality of each species; for, under the same disposition of the Ambient and of the horizon, each various kind of seed prevails in determining the distinct formation of its own proper species; thus man is born, or the horse is foaled; and by the same law are brought forth all the other various creatures and productions of the earth. It is also to be remembered, that considerable variations are caused in all creatures by the respective places where they may be brought forth: for although, under the same disposition of the Ambient, the germs of the future creatures may be of one species, whether human or of the horse, the difference in situation, of the places in which they are generated, produces a dissimilarity in the body and spirit of one from the body and spirit of another: and in addition to this it must be considered that different modes of nurture, and the variety of ranks, manners, and customs, contribute to render the course of life of [Pg 7]one individual greatly different from that of another[23]; consequently, unless every one of these varieties be duly

blended with the causes arising in the Ambient, the prejudgment of any event will doubtless be very incomplete. For, although the greatest multiplicity of power exists in the Ambient, and although all other things act as concurrent causes in unison with it, and can never claim it as a concurrent cause in subservience to them, there will still, nevertheless, be a great deficiency in predictions attempted to be made by means of the heavenly motions alone, without regard to the other concurrent causes just now adverted to.

Under these circumstances, it would seem judicious neither to deny altogether the practicability of prescience, because prognostications thus imperfectly derived are sometimes liable to be fallacious; nor, on the other hand, to admit that all events, whatever, are open to previous inquiry; as if such inquiry could in all cases be securely conducted without having recourse to mere inference, and as if it were not limited by the narrow extent of mere human abilities. The art of navigation, for instance, is not rejected, although it is in many points incomplete; therefore the bare fact that predictions are frequently imperfect cannot authorise the rejection of the art of prescience: the magnitude of its scope, and the faint resemblance that it bears to a divine attribute, should rather demand grateful commendations, and receive the utmost regard and attention. And, since no weakness is imputed to a physician, because he inquires into the individual habit of his patient, as well as into the nature of the disease, no imputation can justly attach to the professor of prognostication, because he combines the consideration of species, nurture, education and country, with that of the motion of the heavens: for as the physician acts but reasonably, in thus considering the proper constitution of the sick person as well as his disease; so, in forming predictions, it must surely be justifiably allowable to comprehend in that consideration every other thing connected with the subject in addition to the motion of the heavens, and to collect and compare with that motion all other co-operating circumstances arising elsewhere.

zain.adwan

[Pg 8]

CHAPTER III

THAT PRESCIENCE IS USEFUL

It appears, then, that prescience by astronomy is possible under certain adaptation; and that alone it will afford premonition, as far as symptoms in the Ambient enable it to do so, of all such events as happen to men by the influence of the Ambient. These events are, from their commencement, always in conformity with the spiritual and corporeal faculties, and their occasional affections; as well as with the shorter or longer duration of those affections. They are also conformable with other things which, although not actually in man's immediate person, are still absolutely and naturally connected with him: in connection with his body they are applicable to his estate, and his conjugal cohabitations; in connection with his spirit, they relate to his offspring[24] and his rank; and they are also connected with all fortuitous circumstances which may occasionally befall him.

That the foreknowledge of these can be attained has already been demonstrated; and it remains to speak of the utility of the attainment. First, however, let it be said in what respect and with what view it is proposed to draw advantage from this science; if it be considered in its tendency to promote the good of the mind, no object more advantageous can surely be wanting to induce the world to rejoice and delight in it, since it offers an acquaintance with things divine and human: if it be considered in respect to the benefits it is capable of conferring on the body, its utility in this view also, will be found on comparison to excel that of all other arts conducive to the comforts of life, for it is of more general application and service than all the others together. And, although it may be objected to the art of prescience, that it does not co-operate towards

the acquirement of riches or glory, let it also be remembered that the same objection attaches to every other art and science; since there is not one which can of itself produce either riches or glory, not yet is there one which is on that plea deemed useless: it seems, therefore, that the science of prognostication, with its high qualifications and its aptitude to the most important objects, does not, in any greater degree, deserve to be condemned.

In general, however, the persons who attack and reprobate it as being useless, do not pay due regard to the manner in which it becomes necessary; but deny its utility on the specious argument that it is [Pg 9]superfluous and puerile to attempt to foreknow things which must inevitably come to pass: thus considering it in a mode at once abstracted, unlearned, and unfair. For, in the first place, this fact ought to be kept in view, that events which necessarily and fully happen, whether exciting fear or creating joy, if arriving unforeseen, will either overwhelm the mind with terror or destroy its composure by sudden delight; if, however, such events should have been foreknown, the mind will have been previously prepared for their reception, and will preserve an equable calmness, by having been accustomed to contemplate the approaching event as though it were present, so that, on its actual arrival, it will be sustained with tranquillity and constancy.

In the next place, it must not be imagined that all things happen to mankind, as though every individual circumstance were ordained by divine decree and some indissoluble supernal cause; nor is it to be thought that all events are shown to proceed from one single inevitable fate, without being influenced by the interposition of any other agency. Such an opinion is entirely inadmissable; for it is on the contrary most essential to observe, not only the heavenly motion which, perfect in its divine institution and order, is eternally regular and undeviating; but also the variety which exists in earthly things, subjected to and diversified by the institutions and courses of nature, and in connection with which the superior cause operates in respect to the accidents produced.

zain n. adwan

It is further to be remarked that man is subject, not only to events applicable to his own private and individual nature, but also to others arising from general causes. He suffers, for instance, by pestilences, inundations, or conflagrations, produced by certain extensive changes in the Ambient, and destroying multitudes at once; since a greater and more powerful agency must of course always absorb and overcome one that is more minute and weaker. In great changes, therefore, where a stronger cause predominates, more general affections, like those just mentioned, are put in operation, but affections which attach to one individual solely are excited when his own natural constitution peculiar to himself may be overcome by some opposing impulse of the Ambient, however small or faint. And in this point of view it is manifest that all events whatsoever, whether general or particular, of which the primary cause is strong and irresistible, and against which no other contrary agency has sufficient power to interpose, must of necessity be wholly fulfilled; and that events indicated by a minor cause must of course be prevented and annihilated, when some other agency may be found contending for an opposite effect; if, however, no such opposing agency can be found, they also must be fulfilled, in due succession to the primary cause. Nevertheless, the fulfilment of events thus indicated must not be ascribed solely to the vigour of the cause producing them, nor to any inevitable fate, but rather to the absence of any opposing influence capable of prevention. And thus, with all [Pg 10]things whatsoeverwhich trace their causes and origin to nature, the case is exactly similar; for stones,[25] plants, animals, wounds, passions, and diseases, all will of necessity operate on man to a certain degree; and they fail to do so, if antidotes be found and applied against their influence.

In exercising prognostication, therefore, strict care must be taken to foretell future events by that natural process only which is admitted in the doctrine here delivered; and, setting aside all vain and unfounded opinions, to predict that, when the existing agency is manifold and great, and of a power impossible to be resisted, the

corresponding event which it indicates shall absolutely take place; and also, in other cases, that another event shall not happen when its exciting causes are counteracted by some interposing influence. It is in this manner that experienced physicians, accustomed to the observation of diseases, foresee that some will be inevitably mortal, and that others are susceptible of cure.

Thus, when any opinion is given by the astrologer with respect to the various accidents liable to happen, it should be understood that he advances nothing more than this proposition; viz. that, by the property inherent in the Ambient, any conformation of it, suitable to a particular temperament, being varied more or less, will produce in that temperament some particular affection. And it is also to be understood that he ventures this opinion with the same degree of confidence, as that with which a physician may declare that a certain wound will increase or grow putrid; or a man acquainted with metals say that the magnet[26] will attract iron. But neither the increase nor putrefaction of the wound nor the magnet's attraction of iron, is ordained by any inevitable law, although these consequences must necessarily follow, in due obedience to the first principles of the existing order of nature, when no means of prevention can be found and applied. But, however, neither of these consequences will take place, when such antidotes shall be presented as will naturally prevent them—and a similar [Pg 11]consideration should be given to the predictions of the astrologer—because, if garlick be rubbed on the magnet, iron will experience no attraction;[27] and if proper medicines be applied to the wound, it will cease to increase or to putrefy. And therefore all events which happen to mankind take place also in the regular course of nature, when no impediments thereto are found or known: but again, on the other hand, if any impediments or obstructions be found in the way of events which may be predicted by the regular course of nature to happen, such events will either not take place at all, or, if they should take place, will be much diminished in their force and extent.

The same order and consequence exist in all cases, whether the events have a general or only a particular operation; and it may therefore well be demanded, why prescience is believed to be possible as far as it regards general events, and why it is allowed to be serviceable in preparing for their approach; while in particular instances its power and use are altogether denied. That the weather and the seasons, and the indications of the fixed stars, as well as the configurations of the Moon, afford means of prognostication, many persons admit; and they exercise this foreknowledge for their own preservation and comfort, adapting their constitutions to the expected temperature, by cooling and refreshing things for the summer, and by warm things for the winter. They also watch the significations of the fixed stars, to avoid dangerous weather, in making voyages by sea; and they notice the [Pg 12]aspects of the Moon, when at the full, in order to direct the copulation of their herds and flocks, and the setting of plants or sewing of seeds: and there is not an individual who considers these general precautions as impossible or unprofitable. Still, however, these same persons withhold their assent to the possibility of applying prescience to particular cases; such, for instance, as any particular excess or diminution of cold or heat, whether arising out of the peculiar temperament producing the original cold or heat, or from the combination of other properties; nor do they admit that there are any means of guarding against many of these particular circumstances. And yet, if it be clear that persons, who prepare themselves by cooling things, are less affected by any general heat of the weather, there seems no reason for supposing that a similar preparation would not be equally effectual against any particular conjuncture oppressed by immoderate heat. It appears, however, that this idea, of the impracticability of attaining foreknowledge of particular circumstances, must originate solely in the mere difficulty of the acquirement; which difficulty is certainly rendered peculiarly arduous by the necessity of conducting the enquiry with the greatest accuracy and precision: and to this it must be added, that, as there is rarely found a person capable of arranging the whole subject so perfectly that no part of the opposing influence can escape his attention, it frequently happens that predictions are

not properly regulated by due consideration of that opposing influence, and that the effects are at once considered fully liable to be brought to pass, agreeably to the primary agency and without any intervention. This defect, of not sufficiently considering the opposing influence, has naturally induced an opinion that all future events are entirely unalterable and inevitable. But, since the foreknowledge of particular circumstances, although it may not wholly claim infallibility, seems yet so far practicable as to merit consideration, so the precaution it affords, in particular circumstances, deserves in like manner to be attended to; and, if it be not of universal advantage, but useful in few instances only, it is still most worthy of estimation, and to be considered of no moderate value. Of this, the Ægyptians seem to have been well aware; their discoveries of the great faculties of this science have exceeded those of other nations, and they have in all cases combined the medical art with astronomical prognostication. And, had they been of opinion that all expected events are unalterable and not to be averted, they never would have instituted any propitiations, remedies, and preservatives against the influence of the Ambient, whether present or approaching, general or particular. But, by means of the science called by them Medical Mathematics, they combined with the power of prognostication the concurrent secondary influence arising out of the institutions and courses of nature, as well as the contrary influence which might be procured out of nature's variety; and by means of these they rendered the indicated agency useful and advantageous: since their [Pg 13]astronomy pointed out to them the kind of temperament liable to be acted upon, as well as the events about to proceed from the Ambient, and the peculiar influence of those events, while their medical skill made them acquainted with everything suitable or unsuitable to each of the effects to be procured. And it is by this process that remedies for present and preservatives against future disorders are to be acquired: for, without astronomical knowledge, medical aid would be most frequently unavailing; since the same identical remedies are not better calculated for all persons whatsoever, than they are for all diseases whatsoever.[28]

The practicability and utility of prescience having been thus far briefly explained, the ensuing discourse must be proceeded with. It commences, introductorily, with an account of the efficient properties of each of the heavenly bodies, taken from the rules of the ancients, whose observations were founded in nature. And, first, of the influences of the planets and of the Sun and Moon.

CHAPTER IV

THE INFLUENCES OF THE PLANETARY ORBS

The Sun[29] is found to produce heat and moderate dryness. His magnitude, and the changes which he so evidently makes in the seasons, render his power more plainly perceptible than that of the other heavenly bodies; since his approach to the zenith of any part of the earth creates a greater degree of heat in that part and proportionately disposes its inhabitants after his own nature.

The Moon principally generates moisture; her proximity to the earth renders her highly capable of exciting damp vapours, and of thus operating sensibly upon animal bodies by relaxation and putrefaction. She has, however, also a moderate share in the production of heat, in consequence of the illumination she receives from the Sun.

Saturn produces cold and dryness, for he is most remote both from the Sun's heat and from the earth's vapours. But he is more effective in the production of cold than of dryness. And he and the rest of the planets derive their energy from the positions which they hold with regard to the Sun and Moon; and they are all seen to alter the constitution of the Ambient in various ways.

Zain n. adwan

Mars chiefly causes dryness, and is also strongly heating, by means of his own fiery nature, which is indicated by his colour, and in consequence of his vicinity to the Sun; the sphere of which is immediately below him.[Pg 14]

Jupiter revolves in an intermediate sphere between the extreme cold of Saturn and the burning heat of Mars, and has consequently a temperate influence: he therefore at once promotes both warmth and moisture. But, owing to the spheres of Mars and the Sun, which lie beneath him, his warmth is predominant: and hence he produces fertilizing breezes.

To Venus also the same temperate quality belongs, although it exists conversely; since the heat she produces by her vicinity to the Sun is not so great as the moisture which she generates by the magnitude of her light, and by appropriating to herself the moist vapours of the earth, in the same manner that the Moon does.

Mercury sometimes produces dryness, and at other times moisture, and each with equal vigour. His faculty of absorbing moisture and creating dryness proceeds from his situation with regard to the Sun, from which he is at no time far distant in longitude; and, on the other hand, he produces moisture, because he borders upon the Moon's sphere, which is nearest to the earth; and, being thus excited by the velocity of his motion with the Sun, he consequently operates rapid changes tending to produce alternately either quality.

CHAPTER V

BENEFICS AND MALEFICS

Of the four temperaments or qualities above mentioned, two are nutritive and prolific, viz. heat and moisture; by these all matter coalesces and is nourished: the other

two are noxious and destructive, viz. dryness and cold; by these all matter is decayed and dissipated.

Therefore, two of the planets, on account of their temperate quality, and because heat and moisture are predominant in them, are considered by the ancients as benefic, or causers of good: these are Jupiter and Venus. And the Moon also is so considered for the same reasons.

But Saturn and Mars are esteemed of a contrary nature, and malefic, or causers of evil: the first from his excess of cold, the other from his excess of dryness.

The Sun and Mercury are deemed of common influence, and productive either of good or evil in unison with whatever planets they may be connected with.

CHAPTER VI

MASCULINE AND FEMININE

There are two primary sexes, male and female; and the female sex partakes chiefly of moisture. The Moon and Venus are therefore said to be feminine, since their qualities are principally moist.

The Sun, Saturn, Jupiter, and Mars are called masculine. Mercury is [Pg 15]common to both genders, because at certain times he produces dryness, and at others moisture, and performs each in an equal ratio.

The stars, however, are also said to be masculine and feminine, by their positions with regard to the Sun. While they are matutine and preceding the Sun, they are masculine; when vespertine and following the Sun, they become feminine.[30]

And they are further regulated in this respect by their positions with regard to the horizon. From the ascendant to the mid-heaven, or from the angle of the west to the

zaid.adwan

lower heaven, they are considered to be masculine, being then oriental: and in the other two quadrants, feminine, being then occidental.

CHAPTER VII

DIURNAL AND NOCTURNAL

The day and the night are the visible divisions of time. The day, in its heat and its aptitude for action, is masculine:—the night, in its moisture and its appropriation to rest, feminine.

Hence, again, the Moon and Venus are esteemed to be nocturnal; the Sun and Jupiter, diurnal; and Mercury, common; since in his matutine position he is diurnal, but nocturnal when vespertine.

Of the other two planets, Saturn and Mars, which are noxious, one is considered to be diurnal, and the other nocturnal. Neither of them, however, is allotted to that division of time with which its nature accords (as heat accords with heat), but each is disposed of on a contrary principle: and for this reason, that, although the benefit is increased when a favourable temperament receives an addition of its own nature, yet, the evil arising from a pernicious influence is much mitigated when dissimilar qualities are mingled with that influence. Hence the coldness of Saturn is allotted to the day, to counterbalance its heat; and the dryness of Mars to the night, to counterbalance its moisture. Thus each of these planets, being moderated by this combination, is placed in a condition calculated to produce a favourable temperament.[31]

[Pg 16]

CHAPTER VIII

THE INFLUENCE OF POSITION
WITH REGARD TO THE SUN

The respective powers of the Moon and of the three superior planets are either augmented or diminished by their several positions with regard to the Sun.

The Moon, during her increase, from her first emerging to her first quarter, produces chiefly moisture; on continuing her increase from her first quarter to her full state of illumination, she causes heat; from her full state to her third quarter she causes dryness; and from her third quarter to her occultation she causes cold.

The planets, when matutine, and from their first emerging until they arrive at their first station, are chiefly productive of moisture; from their first station until they rise at night, of heat; from their rising at night until their second station, of dryness; and from their second station until their occultation, they produce cold.[32]

But it is also sufficiently plain that they must likewise cause, by their intermixture with each other, many varieties of quality in the Ambient: because, although their individual and peculiar influence may for the most part prevail, it will still be more or less varied by the power of the other heavenly bodies configurated with them.

CHAPTER IX

THE INFLUENCE OF THE FIXED STARS

Next in succession, it is necessary to detail the natures and properties of the fixed stars; all of which have their respective influences, analogous to the influences of the planets: and those stars which form the constellations of the zodiac require to be first described.

zaid n. adwan

Aries. The stars in the head of Aries possess an influence similar in its effects to that of Mars and Saturn: those in the mouth act similarly to Mercury, and in some degree to Saturn; those in the hinder foot, to Mars; those in the tail, to Venus.[Pg 17]

Taurus. Those stars in Taurus, which are in the abscission of the sign, resemble in their temperament the influence of Venus, and in some degree that of Saturn: those in the Pleiades are like the Moon and Mars. Of the stars in the head, that one of the Hyades which is bright and ruddy, and called Facula,[33] has the same temperament as Mars: the others resemble Saturn, and, partly, Mercury; and those at the top of the horns are like Mars.

Gemini. The stars in the feet of Gemini have an influence similar to that of Mercury, and moderately to that of Venus.

The bright stars in the thighs are like Saturn: of the two bright stars on the heads, the one, which precedes and is called Apollo,[34] is like Mercury; the other which follows, called Hercules,[35] is like Mars.

Cancer. The two stars in the eyes of Cancer are of the same influence as Mercury, and are also moderately like Mars. Those in the claws are like Saturn and Mercury. The nebulous mass in the breast, called the Præsepe, has the same efficacy as Mars and the Moon. The two placed on either side of the nebulous mass, and called the Asini, have an influence similar to that of Mars and the Sun.

Leo. Of the stars in Leo, two in the head are like Saturn and partly like Mars. The three in the neck are like Saturn, and in some degree like Mercury. The bright one in the heart, called Regulus,[36] agrees with Mars and Jupiter. Those in the loins, and the bright one in the tail, are like Saturn and Venus: those in the thighs resemble Venus, and, in some degree, Mercury.

Virgo. The stars in the head of Virgo, and that at the top of the southern wing, operate like Mercury and somewhat like Mars: the other bright stars in the same wing, and those

about the girdle, resemble Mercury in their influence, and also Venus moderately. The bright one in the northern wing, called Vindemiator, is of the same influence as Saturn and Mercury: that called Spica Virginis is like Venus and partly Mars: those at the points of the feet and at the bottom of the garments are like Mercury, and also Mars, moderately.

Libra.[37] Those stars at the points of the claws of Scorpio operate like Jupiter and Mercury: those in the middle of the claws, like Saturn, and in some degree like Mars.

[Pg 18]*Scorpio.* The bright stars in the front of the body of Scorpio have an effect similar to that produced by the influence of Mars, and partly to that produced by Saturn: the three in the body itself, the middle one of which, called Antares,[38] is ruddy and more luminous, are similar to Mars and moderately to Jupiter: those in the joints of the tail are like Saturn and partly like Venus: those in the sting, like Mercury and Mars. The nebula is like Mars and the Moon.

Sagittarius. The stars at the point of the arrow in Sagittarius have influence similar to that of Mars and the Moon: those on the bow, and at the grasp of the hand, act like Jupiter and Mars: the nebula in the face is like the Sun and Mars: those in the waist and in the back resemble Jupiter, and also Mercury moderately: those in the feet, Jupiter and Saturn: the four-sided figure in the tail is similar to Venus, and in some degree to Saturn.

Capricorn. The stars in the horns of Capricorn have efficacy similar to that of Venus, and partly to that of Mars. The stars in the mouth are like Saturn, and partly like Venus: those in the feet and in the belly act in the same manner as Mars and Mercury: those in the tail are like Saturn and Jupiter.

Aquarius. The stars in the shoulders of Aquarius operate like Saturn and Mercury; those in the left hand and in the face do the same: those in the thighs have an influence more consonant with that of Mercury, and in a less degree with that of Saturn: those in

the stream of water have power similar to that of Saturn, and, moderately, to that of Jupiter.

Pisces. Those stars in Pisces, which are in the head of the southern fish, have the same influence as Mercury, and, in some degree, as Saturn: those in the body are like Jupiter and Mercury: those in the tail and in the southern line are like Saturn, and, moderately, like Mercury. In the northern fish, those on its body and back-bone resemble Jupiter, and also Venus in some degree: those in the northern line are like Saturn and Jupiter; and the bright star in the knot acts like Mars, and moderately like Mercury.[39]

[Pg 19]

CHAPTER X

CONSTELLATIONS NORTH OF THE ZODIAC

The constellations north of the zodiac have their respective influences, analogous to those of the planets, existing in the mode described in the following list.

- *Ursa Minor.* The bright stars in this constellation
    - are like Saturn, and in some degree like Venus.
- *Ursa Major* is like Mars, but the nebula under the
    - tail resembles the Moon and Venus in its influence.
- *Draco.* The bright stars operate like Saturn and Mars.
- *Cepheus* is like Saturn and Jupiter.
- *Bootes* is like Mercury and Saturn; but the bright and
    - ruddy star, called Arcturus, is like Mars and Jupiter.
- *Corona Borealis* is like Venus and Mercury.

zaid.adwan

- *Hercules* (or the Kneeler) is like Mercury.
- *Lyra* is like Venus and Mercury.
- *Cygnus* is like Venus and Mercury.
- *Cassiopeia* is like Saturn and Venus.
- *Perseus* is like Jupiter and Saturn: but the nebula,
    - in the hilt of the sword, is like Mars and Mercury.
- *Auriga.* The bright stars are like Mars and Mercury.
- *Serpentarius* is like Saturn, and moderately like Venus.
- *Serpens* is like Saturn and Mars.
- *Sagitta* is like Saturn, and moderately like Venus.
- *Aquila* is like Mars and Jupiter.
- *Delphinus* is like Saturn and Mars.
- *Equus* (or Pegasus). The bright stars are like Mars and Mercury.
- *Andromeda* is like Venus.
- *Delta* (or the Triangle) is like Mercury.

[Pg 20]

CHAPTER XI

CONSTELLATIONS SOUTH OF THE ZODIAC

The influences of the constellations south of the zodiac, existing in a similar mode, are as follows:—

- *Piscis Australis.* The bright star in the mouth is of the same
    - influence as Venus and Mercury.
- *Cetus* is like Saturn.

zaid n. adwan

- *Orion.* The stars on the shoulders operate similarly to Mars and
    - Mercury; and the other bright stars to Jupiter and Saturn.
- *Fluvius* (or *Eridanus*). The last bright one is of
    - the same influence as Jupiter; the rest are like Saturn.
- *Lepus* is like Saturn and Mercury.
- *Canis.* The bright star in the mouth is like Jupiter, and
    - partly like Mars: the others are like Venus.
- *Procyon.*[40] The bright star is like Mercury, and in some
    - degree like Mars.
- *Hydrus.* The bright stars are like Saturn and Venus.
- *Crater* is like Venus, and in some degree like Mercury.
- *Corvus* is like Mars and Saturn.
- *Argo.* The bright stars are like Saturn and Jupiter.
- *Centaurus.* The stars in the human part of the figure are
    - of the same influence as Venus and Mercury; the bright
    - stars in the horse's part are like Venus and Jupiter.
- *Lupus.* The bright stars are like Saturn, and partly like Mars.
- *Ara* is like Venus, and also Mercury in some degree.
- *Corona Australis.* The bright stars are like Saturn and Jupiter.

The respective influences of the several stars have been observed by the ancients to operate in conformity with the mode pointed out in the foregoing distributions.[41]

[Pg 21]

CHAPTER XII

THE ANNUAL SEASONS

zain-adwan

The year comprises four seasons; spring, summer, autumn, and winter; of these, the spring partakes chiefly of moisture, for on the dissipation of cold and recommencement of warmth, an expansion of the fluids takes place: the summer is principally hot, owing to the Sun's nearest approach to the zenith: the autumn is principally dry, because the recent heat has absorbed the moisture: and the winter is chiefly cold, the Sun being then at his farthest distance from the zenith.

The beginning of the whole zodiacal circle (which in its nature as a circle can have no other beginning, nor end, capable of being determined), is therefore assumed to be the sign of Aries, which commences at the vernal equinox:[42] since the moisture of spring forms a primary beginning in the zodiac, analogous to the beginning of all animal life; which, in its first age of existence, abounds principally in moisture: the spring, too, like the first age of animal life, is soft and tender; it is therefore suitably placed as the opening of the year, and is followed by the other seasons in appropriate succession. The summer comes second, and, in its vigour and heat, agrees with the second age of animals; the prime of life, and the period most abounding in heat. Again, the age when the prime of life has passed away, and in which decay prepares to advance, is chiefly abundant in dryness, and corresponds to the autumn. And the final period of old age, hastening to dissolution, is principally cold, like the winter.

CHAPTER XIII

THE INFLUENCE OF THE FOUR ANGLES

The angles are the four cardinal points of the horizon, whence are derived the general names of the winds. With respect to their qualities, it is to be observed that the eastern point, or angle of the [Pg 22]ascendant, is chiefly dry in its nature; because, on the Sun's arrival therein, the damps occasioned by the night begin to be dried up: and all winds

zaidn.adwan

blowing from that quarter, under the common name of east winds, are arid and free from moisture.

The southern point, or angle of the mid-heaven, is the most hot; because the Sun's meridan position, which produces greater warmth and heat, declines (in this part of the earth) towards the south. The winds, therefore, which blow from that quarter, and are commonly called south winds, are hot and rarefying.

The western point, or occidental angle, is moist; because, when the Sun is there, the moisture, which had been overpowered during the day, recommences its operation: and the winds proceeding from thence, and commonly called west winds, are light and damp.

The northern point, or angle of the lower heaven, is the most cold; for the Sun's meridian position in this part of the earth is far removed from it in declination: and all winds thence proceeding, under the common name of north winds, are cold and frosty.

It will, of course, be seen that a thorough acquaintance with the foregoing matters is essential in order to acquire the faculty of distinguishing temperaments in every shape and variation: since it is sufficiently obvious that the effective influence of the stars must be greatly diversified by the constitutions of the seasons, as well as those of the ages of life, and of the angles; and also that the stars have a much stronger influence on any constitution, when there may not be in it any tendency contrary to their own, as the whole influence is then entire and unalloyed. For example, stars effecting heat operate more vigorously in constitutions of heat; and those effecting moisture in constitutions of moisture. On the other hand, should a tendency, contrary to their own, exist in any constitution, the stars accordingly become less efficacious; in consequence of being attempered and mixed with that contrary tendency: and this happens, for instance, when stars effecting heat are attempered by constitutions of cold, or stars producing moisture by constitutions of dryness. The influence of every star is thus modified by the proportionate admixture presented by constitutions of a nature different from its own.

Zaid H. adwan

In succession to the previous instructions, the following description of the natural and peculiar properties of the signs of the zodiac is annexed: the general temperaments of the signs are analogous to those of the seasons, which are respectively established under each sign, but they have, also, certain peculiar energies, arising from their familiarity with the Sun, the Moon, and the stars, which shall be hereafter specified;—and the simple and unmixed influences existing in the signs, as considered only in themselves and with regard to each other, will be first stated.

[Pg 23]

CHAPTER XIV

TROPICAL, EQUINOCTIAL, FIXED,
AND BICORPOREAL SIGNS

Among the twelve signs, some are termed tropical, others equinoctial, others fixed, and others bicorporeal.

The tropical signs are two: viz. the first thirty degrees after the summer solstice, which compose the sign of Cancer; and the first thirty degrees after the winter solstice, composing the sign of Capricorn. These are called *tropical*, because the Sun, after he has arrived at their first points, seems to *turn*, and to change his course towards a contrary latitude;[43] causing summer by the *turn* he makes in Cancer, and winter by that which he makes in Capricorn.

There are also two equinoctial signs: Aries, the first after the vernal equinox; and Libra, the first after the autumnal equinox: they are so called, because the Sun, when in the first point of either, makes the day and night equal.

Zaid n. adwan

Of the remaining eight signs, four are fixed, and four bicorporeal. Those signs, which severally follow immediately after the two tropical and the two equinoctial signs, are termed fixed, because, during the Sun's presence in them, the cold, heat, moisture or dryness, of the season, which commenced on his arrival in the preceding tropical or equinoctial sign, is then more firmly established: not, however, that the temperament of the season has in itself actually increased in vigour, but, having continued for some time in operation, it then renders all things more strongly affected by its influence.

The bicorporeal signs severally follow the fixed signs; and, being thus intermediately placed between the fixed and the tropical signs, they participate in the constitutional properties of both, from their first to their last degrees.

CHAPTER XV

MASCULINE AND FEMININE SIGNS

Again, among the twelve signs, six are called masculine and diurnal, and six feminine and nocturnal. They are arranged in alternate order, one after the other, as the day is followed by the night, and as the male is coupled with the female.

The commencement, it has been already said, belongs to Aries; since the moisture of the spring forms an introduction for the other seasons. And, [Pg 24]as the male sex governs, and the active principle takes precedence of the passive, the signs of Aries and Libra are consequently considered to be masculine and diurnal. These signs describe the equinoctial circle, and from them proceed the principal variation, and most powerful agitation, of all things. The signs immediately following them are feminine and nocturnal; and the rest are consecutively arranged as masculine and feminine, by alternate order.

Masculine or feminine qualities are, however, by some persons, attributed to the signs by means of a different arrangement, and by making the sign ascending (which is also called the horoscope) the first of the masculine signs. They also consider the first tropical sign to be that in which the Moon is posited, because she undergoes more frequent and rapid changes and variations than any other heavenly body; and it is by a similar mode of reasoning that they establish the horoscope as the first masculine sign, on account of its being more immediately under the Sun. Again, certain of these persons likewise allow the alternate arrangement of the signs; while there are, again, others who do not admit it; but, instead thereof, divide the whole zodiac into quadrants, and denominate those between the ascendant and the mid-heaven, and between the western angle and the lower haven, oriental and masculine; and the other two quadrants, occidental and feminine.

There have also been other additional appellations bestowed on the signs, in consequence of their apparent formations and figures: they have been called quadrupedal, terrestrial, imperial, fruitful, and have received various other distinguishing epithets of the same sort; but these distinctions seem too unimportant to be even enumerated here, since their origin is obvious, and since, should they ever be thought serviceable towards the inference of future effects, they may be easily applied without the aid of further instruction.

zaid n. adwan

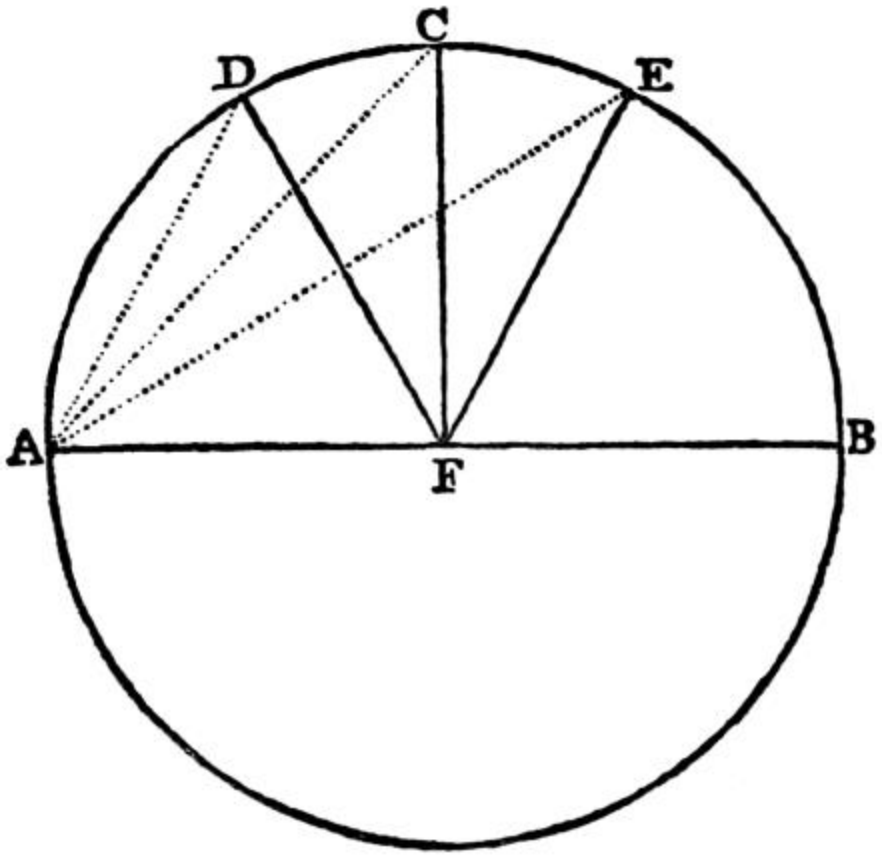
CHAPTER XVI

MUTUAL CONFIGURATIONS OF THE SIGNS

There are certain familiarities or connections between different parts of the zodiac; and the chief of these is that which exists between such parts as are configurated with each other.

This mutual configuration attaches to all parts diametrically distant from each other, containing between them two right angles, or six signs, or a hundred and eighty degrees: it also exists in all parts at the triangular distance from each other, containing between them one right angle and a third, or four signs, or a hundred and twenty degrees; also, in all parts at the quadrate distance from each other, containing between them exactly one right angle, or three signs, or ninety degrees; and, also, in all parts at the hexagonal distance from each other, containing between them two-thirds of a right angle, or two [Pg 25]signs, or sixty degrees.[44] These several distances are taken for the following reasons: the distance by diameter, however, is in itself sufficiently clear, and requires no further explanation; but, as to the rest, after the diametrical points have been connected by a straight line, AB; the space of the two right angles, contained on the diameter, is then to be divided into aliquot parts of the two greatest denominations; that is to say, into halves, AFC, CFB, and into thirds, AFD, DFE, EFB: there will then be provided for the third part (AD) a super-proportion (DC), equal to its own half; and for the half (AC) a super-proportion (CE), equal to its own third part; so that the division into two aliquot parts, AC, CB, will make the quartile distance AC; and the division into three aliquot parts, AD, DE, EB, will make the sextile distance AD, and the trinal distance AE. The respective super-proportions (on either side of the intermediate quartile AC, formed by the one right angle AFC), will also again make the quartile AC (if there be added to the sextile, AD, the super-proportion DC, equal to the half of the sextile), and the trine AE (if there be added to the quartile AC the super-proportion CE, equal to the third part of the quartile).

Zaid H. adwan



[Pg 26]Of these configurations, the trine and the sextile are each called harmonious, because they are constituted between signs of the same kind; being formed between either all feminine or all masculine signs. The opposition and quartile are considered to be discordant, because they are configurations made between signs not of the same kind, but of different natures and sexes.[45]

CHAPTER XVII

SIGNS COMMANDING AND OBEYING

Any two signs configurated with each other at an equal distance from the same, or from either equinoctial point, are termed commanding and obeying, because the

ascensional and descensional times of the one are equal to those of the other, and both describe equal parallels.

The signs in the summer semicircle are commanding; those in the winter semicircle, obeying: for, when the Sun is present in the former, he makes the day longer than the night; and, when in the latter, he produces the contrary effect.

CHAPTER XVIII

SIGNS BEHOLDING EACH OTHER,
AND OF EQUAL POWER

Any two signs, equally distant from either tropical sign, are equal to each other in power; because the Sun, when present in one, makes day and night, and the divisions of time, respectively equal in duration to those which he produces when present in the other. Such signs are also said to behold each other, as well for the foregoing reasons, as because each of them rises from one and the same part of the horizon, and sets in one and the same part.[46]

[Pg 27]

CHAPTER XIX

SIGNS INCONJUNCT

All signs, between which there does not exist any familiarity in any of the modes above specified, are inconjunct and separated.

zaid n. adwan

For instance, all signs are inconjunct which are neither commanding nor obeying, and not beholding each other nor of equal power, as well as all signs which contain between them the space of one sign only, or the space of five signs, and which do not at all share in any of the four prescribed configurations: viz. the opposition, the trine, the quartile, and the sextile. All parts which are distant from each other in the space of one sign only are considered inconjunct, because they are averted, as it were, from each other; and because, although the said space between them may extend into two signs, the whole only contains an angle equal to that of one sign: all parts distant from each other in the space of five signs are also considered inconjunct, because they divide the whole circle into unequal parts; whereas the spaces contained in the configurations above mentioned, viz. the opposition, trine, quartile, and sextile, produce aliquot divisions.[47]

[Pg 28]

CHAPTER XX

HOUSES OF THE PLANETS

Those stars which are denominated planetary orbs have particular familiarity with certain places in the zodiac, by means of parts designated as their houses, and also by their triplicities, exaltations, terms, and so forth.

The nature of their familiarity by houses is as follows:

Cancer and Leo are the most northerly of all the twelve signs; they approach nearer than the other signs to the zenith of this part of the earth, and thereby cause warmth and heat: they are consequently appropriated as houses for the two principal and greater luminaries; Leo for the Sun, as being masculine; and Cancer for the Moon, as being

Zaid n. adwan

feminine. It has hence resulted, that the semicircle from Leo to Capricorn has been ordained solar, and the semicircle from Aquarius to Cancer, lunar; in order that each planet might occupy one sign in each semicircle, and thus have one of its houses configurated with the Sun and the other with the Moon, conformably to the motions of its own sphere, and the peculiar properties of its nature.

Saturn, therefore, since he is cold and inimical to heat, moving also in a superior orbit most remote from the luminaries, occupies the signs opposite to Cancer and Leo: these are Aquarius and Capricorn; and they are assigned to him in consideration of their cold and wintry nature; and because the configuration by opposition does not co-operate towards the production of good.[48]

Jupiter has a favourable temperament, and is situated beneath the sphere of Saturn; he therefore occupies the next two signs, Sagittarius [Pg 29]and Pisces. These signs are airy and fruitful, in consequence of their trinal distance from the houses of the luminaries, which distance harmonises with the operation of good.

Mars is dry in nature, and beneath the sphere of Jupiter: he takes the next two signs, of a nature similar to his own, viz. Aries and Scorpio, whose relative distances from the houses of the luminaries are injurious and discordant.

Venus, possessing a favourable temperament, and placed beneath the sphere of Mars, takes the next two signs, Taurus and Libra. These are of a fruitful nature, and preserve harmony by the sextile distance; and this planet is never more than two signs distant from the Sun.

Mercury never has greater distance from the Sun than the space of one sign, and is beneath all the other planets: hence he is placed nearest to both luminaries, and the remaining two signs, Gemini and Virgo, are allotted to him.[49]

CHAPTER XXI

THE TRIPLICITIES

The familiarity existing by triplicity arises in the following mode:

The triplicity preserves accordance with an equilateral triangle, and the whole zodiacal orbit is defined by three circles, viz. that of the equinox, and those of the two tropics; the twelve signs are, therefore, distributed among four equilateral triangles.

The first triangle, or triplicity, is formed by three masculine signs, Aries, Leo, and Sagittarius, having the Sun, Jupiter, and Mars as lords by house. Mars, however, being contrary in condition to the solar influence, this triplicity receives, as its lords, only Jupiter and the Sun. By day, therefore, the Sun claims the principal co-regency of it, and Jupiter by night. Aries is on the equinoctial circle, Leo on the summer, and Sagittarius on the winter circle. This triplicity is principally northern, owing to the concurrent dominion of Jupiter, who is fruitful and airy, and expressly connected with winds proceeding from the north; it is, however, also north-west, in consequence of [Pg 30]being, in some degree, combined with the west by means of the house of Mars, who introduces western breezes and the feminine qualities of that quarter, in consequence of his lunar condition.[50]

The second triplicity, formed by Taurus, Virgo, and Capricorn, is allotted to the dominion of the Moon and Venus, since it consists of feminine signs. The Moon rules it by night, and Venus by day. Taurus is on the summer circle, Virgo on the equinoctial, and Capricorn on the winter. This triplicity is southern, in consequence of the dominion of Venus, whose warm and moist influence produces south winds: it, however, additionally receives a mixture of the east, by means of Saturn; for, as Capricorn is the house of that planet, and an eastern sign, Saturn becomes effective of winds from that quarter, and furnishes this triplicity with a mixture of the east, with which quarter he is further connected by means of his solar condition.[51]

The third triplicity is composed of Gemini, Libra, and Aquarius, masculine signs. It holds connection with Saturn and Mercury by containing their houses, and is therefore attributed to them, and not to Mars, to which planet it bears no relation. Saturn rules it by day, owing to his condition,[52] and Mercury by night. Gemini is on the summer circle, Libra on the equinoctial, and Aquarius on the winter. This triplicity is principally eastern, by the influence of Saturn; but it becomes north-east by receiving also a mixture of the north from the condition of Jupiter, with which planet Saturn has, in this respect, a diurnal familiarity.[53]

The fourth triplicity, formed by Cancer, Scorpio, and Pisces, is left to the remaining planet, Mars, who has right in it by means of his house, Scorpio. But, as the signs which compose this triplicity are feminine, the Moon by night and Venus by day, through their feminine condition, govern it, together with Mars. Cancer is on the summer circle, Scorpio on the winter, and Pisces on the equinoctial. This triplicity is western, in consequence of the government of the Moon and Mars; but it is also blended with the south by the joint dominion of Venus, and therefore becomes south-west.

[Pg 31]

CHAPTER XXII

EXALTATIONS

That which is termed the exaltation of the planets is considered by the following rules:

The Sun on his entrance into Aries is then passing into the higher and more northern semicircle; but, on his entrance into Libra, into the more southern and lower one: his exaltation, therefore, is determined to be in Aries, as, when present in that sign, he

zaid n. adwan

begins to lengthen the days, and the influence of his heating nature increases at the same time. His fall is placed in Libra, for the converse reasons.

Saturn on the contrary, in order to preserve his station opposite to the Sun, in this respect, as well as in regard to their respective houses, obtains his exaltation in Libra, and his fall in Aries: since, in all cases, the increase of heat must be attended by a diminution of cold, and the increase of cold by a diminution of heat.

The Moon, again, after conjunction with the Sun in Aries, the seat of his exaltation, makes her first appearance, and begins to augment her light in Taurus, the first sign of her own triplicity, which is consequently ascribed to be her exaltation; while Scorpio, the opposite sign, is her fall.

Jupiter, since he is efficacious in exciting fruitful breezes from the north, and since he becomes most northerly, and augments his peculiar influence when in Cancer, accordingly obtains his exaltation in that sign, and his fall in Capricorn.

Mars possesses a fiery nature, which receives its greatest intensity in Capricorn, in which sign this planet becomes most southerly; his exaltation is therefore placed in Capricorn, in opposition to that of Jupiter, and his fall in Cancer.

Venus is of a moist nature, and becomes chiefly moist when in Pisces. Under that sign a dampness begins to be perceptible in the atmosphere, and Venus, from being in that sign, derives an augmentation of her own proper influence: her exaltation is consequently placed therein, and her fall in Virgo.

Mercury is of a nature opposite to that of Venus, and is more dry: in opposition to her, therefore, he takes his exaltation in Virgo, in which sign the autumnal dryness makes its first appearance; and he receives his fall in Pisces.

zain-adwan

[Pg 32]

CHAPTER XXIII

THE DISPOSITION OF THE TERMS[54]

There are two methods of disposing the terms of the planets, in reference to the dominion of the triplicities; one is Ægyptian, the other Chaldaic.

But the Ægyptian method preserves no regular distribution, neither in point of successive order nor in point of quantity.

In point of order it is defective, since it, in some instances, allots the first degrees of a sign to the lord of the house, in others to the lord of the triplicity, and in others again to the lord of the exaltation. By selecting examples this failure in order will easily be seen; for instance, if the order were regulated by the government of houses, for what reason should Saturn take the first degrees in Libra, since that sign is the house of Venus? or why should Jupiter take them in Aries, which is the house of Mars? If the government of triplicities were followed, for what reason should Mercury take the first degrees in Capricorn, which is in the triplicity ruled by Venus? If the government by exaltations, why should Mars take the first degrees in Cancer? that sign being the exaltation of Jupiter. And if the order were regulated even by considering the planet which possesses most of these dignities in the sign, for what reason should Mercury take the first degrees in Aquarius, in which sign he rules only by triplicity, and why not Saturn, who has government in it by house, as well as by triplicity? or why in short should Mercury, who does not possess any kind of dominion in Capricorn, receive the first degrees in that sign also? The same want of order is abundantly evident in the rest of the distribution.

An equal irregularity exists in the respective quantities of degrees allotted by the Ægyptians to the several terms of the planets. For it is by no means a proper nor sufficient demonstration of accuracy that the aggregate sum of all the numbers of every

single planet amounts to the precise total requiring to be divided into portions of time;[55] since, even if it be admitted that this total, collected from every single star, is correctly asserted by the Ægyptians, it may still be objected that the same total, so collected by them, may be found in [Pg 33]many other ways by interchanging the numbers in a sign. There are persons also who contend that in every latitude the same space of time is occupied in ascension by every star; this, however, is manifestly wrong: for, in the first place, these persons are guided by the vulgar opinion of the plane heights of ascension, which is totally foreign to truth, and according to which, in the parallel of Lower Ægypt, the signs of Virgo and Libra would ascend each in thirty-eight degrees and a third,[56] and Leo and Scorpio each in thirty-five degrees; when it is, on the contrary, shown by the Tables,[57] that the latter two signs occupy in their several ascensions more than thirty-five degrees each, but Virgo and Libra less. It should further be observed, that those who support this opinion seem (by so doing) not only to dispute the quantity of the terms most generally received, but to be driven also to the necessity of falsifying many points; since (as it is indispensable to keep to the same total amount of all the terms together) they make use of parts of degrees; but even that contrivance does not enable them to reach the true point.

The old terms, admitted by many persons on the authority of former tradition, are as follows:

THE TERMS ACCORDING TO THE ÆGYPTIANS

Aries			Taurus			Gemini			Cancer			Leo			Virgo		
Jupiter	6	6	Ven.	8	8	Mer.	6	6	Mars	7	7	Jup.	6	6	Mer.	7	7
Venus	6	12	Mer.	6	14	Jup.	6	12	Ven.	6	13	Ven.	5	11	Ven.	10	17

Aries			Taurus			Gemini			Cancer			Leo			Virgo		
Mercury	8	20	Jup.	8	22	Ven.	5	17	Mer.	6	19	Sat.	7	18	Jup.	4	21
Mars	5	25	Sat.	5	27	Mars	7	24	Jup.	7	26	Mer.	6	24	Mars	7	28
Saturn	5	30	Mars	3	30	Sat.	6	30	Sat.	4	30	Mars	6	30	Sat.	2	30
Libra			**Scorpio**			**Sagittarius**			**Capricorn**			**Aquarius**			**Pisces**		
Saturn	6	6	Mars	7	7	Jup.	12	12	Mer.	7	7	Mer.	7	7	Ven.	12	12
Mercury	8	14	Ven.	4	11	Ven.	5	17	Jup.	7	14	Ven.	6	13	Jup.	4	16
Jupiter	7	21	Mer.	8	19	Mer.	4	21	Ven.	8	22	Jup.	7	20	Mer.	3	19
Venus	7	28	Jup.	5	24	Sat.	5	26	Sat.	4	26	Mars	5	25	Mars	9	28
Mars	2	30	Sat.	6	30	Mars	4	30	Mars	4	30	Sat.	5	30	Sat.	2	30

[Pg 34]Thus, by the *Æ*gyptian distribution, it appears that the total numbers of the degrees for each planet, added together, make 360:—viz. for Saturn 57, Jupiter 79, Mars 66, Venus 82, and Mercury 76.

Zain Nadwan

The method of the Chaldæans contains a certain simplicity of arrangement as to quantity, and preserves an order of succession rather more comformable to the dominion of the triplicities. It is, nevertheless, highly imperfect, as may be easily discovered even without being pointed out: for in the first triplicity (which the Chaldæans also attribute to the same signs; viz. Aries, Leo, and Sagittarius), Jupiter, the lord of the triplicity, takes the first degrees; Venus, who rules the next triplicity, follows him; after her, in succession, are Saturn and Mercury, the lords of the triplicity of Gemini; and lastly Mars, lord of the remaining triplicity. In the second triplicity (also allotted to the same signs, viz. Taurus, Virgo, and Capricorn), Venus stands first; next to her, Saturn and Mercury; after them Mars, and Jupiter last. In the other two triplicities a similar order of succession is closely followed; and with respect to the third triplicity, which is ascribed to two lords, viz. to Saturn and Mercury, Saturn is placed first in order by day and Mercury by night.

The quantity of degrees allotted to each planet is also simply regulated in the Chaldaic method; it diminishes in graduation from the quantity given to the planet first in order, so that each successive planet takes one degree less than that which preceded it. Thus the first planet takes eight degrees, the second seven, the third six, the fourth five, and the fifth four. By this arrangement the degrees of Saturn amount by day to 78, and by night to 66; the degrees of Jupiter to 72, of Mars to 69, of Venus to 75, and of Mercury by day to 66, and by night to 78—the whole amounting to 360.

Of these two distributions of the terms, that of the Ægyptians seems more to be relied on than the other; since it has been handed down and recommended in the writings of the Ægyptian authors, and also because the degrees of the terms, in nativities rectified by them as examples, are universally in accordance with this distribution; while, on the other hand, neither the order nor the number of the Chaldaic method has ever been recorded or explained by any writer—not even by the writers of that very

zaid n. adwan

nation: the accuracy of that method is consequently doubtful, and its irregularity as to the order of placing the planets is widely open to censure.

There is, however, an ancient writing which has fallen into the author's possession, and which gives a rational and consistent account of the nature of the terms; of the order in which they are to be taken, and of the quantity belonging to each. It will be found in the subsequent chapter.

[Pg 35]

CHAPTER XXIV

THE TERMS ACCORDING TO PTOLEMY

In arranging the order in which the planets take their terms in each sign, their exaltations, triplicities, and houses, are taken into consideration; and whatever planet, whether benefic or malefic, may possess two rights of dominion in one and the same sign, such planet is universally placed first in order in that sign. In other cases, however, where it does not happen that a malefic possesses two rights of dominion in the sign, it is always placed last.

The lord of the exaltation is placed first; then the lord of the triplicity; and then the lord of the house; in regular succession, according to the series of the signs; but it must again be remembered that any planet, having two rights of dominion in the same sign, takes precedence, as before mentioned, of those having only one. In Cancer and Leo, however, the malefics occupy the first degrees; as those signs are the houses of the Moon and the Sun, which take no terms; and the malefics being found to have greater potency in those signs therefore take precedence in them. Mars, consequently, receives

zaid n. adwan

the first degrees in Cancer, and Saturn in Leo, by which arrangement a proper order is preserved.[58]

The respective quantities of degrees for the several terms is thus determined: viz. when there is no planet found to be lord by two rights in the same sign, or in the two signs next following, each of the benefics, Jupiter and Venus, takes seven degrees; the malefics, Saturn and Mars, take five degrees each; and Mercury, being of common influence, takes six degrees; thus completing the whole thirty. Since, however, there are some cases in which a planet has always a double right—(for Venus obtains the sole government of Taurus and Pisces, as the Moon does not share in the terms)—it is to be observed that when such double right (whether it exist in the same sign or in the signs next following as far as may complete a quadrant) may be possessed by any planet, that planet receives in addition one degree. The planets thus entitled were distinguished by points in the ancient writing above mentioned. And the degree, added to the quantity of the planet which exercises a double right, is subtracted from those of single right; most generally from Saturn and Jupiter, in consequence of their slower motion.[Pg 36]

These terms are detailed in the following table:—

Aries			**Taurus**			**Gemini**			**Cancer**			**Leo**			**Virgo**		
Jupiter	6	6	Ven.	8	8	Mer.	7	7	Mars	6	6	Jup. Sat.	6	6	Mer.	7	7
Venus	8	14	Mer.	7	15	Jup.	6	13	Mer. Jup.	7	13	Mer.	7	13	Ven.	6	13
Mercury	7	21	Jup.	7	22	Ven.	7	20	Jup. Mer.	7	20	Sat. Ven.	6	19	Jup.	5	18

Aries			Taurus			Gemini			Cancer			Leo			Virgo		
Mars	5	26	Sat.	2 4	4 26	Mars	6	26	Ven.	7	27	Jup.	6	25	Sat.	6	24
Saturn	4	30	Mars	6 4	30	Sat.	4	30	Sat.	3	30	Mars	5	30	Mars	6	30
Libra			**Scorpio**			**Sagittarius**			**Capricorn**			**Aquarius**			**Pisces**		
Saturn	6	6	Mars	6	6	Jup.	8	8	Ven.	6	6	Sat.	6	6	Ven.	8	8
Venus	5	11	Ven. Jup.	8 7	14 13	Ven.	6	14	Mer.	6	12	Mer.	6	12	Jup.	6	14

CHAPTER XXV

THE PLACES AND DEGREES OF EVERY PLANET

The signs have been subdivided by some persons into parts still more minute, which have been named places and degrees of dominion. Thus the twelfth part of a sign, or two degrees and a half, has been called a place, and the dominion of it given to the signs next succeeding. Other persons again, pursuing various modes of arrangement, attribute to each planet certain degrees, as being aboriginally connected with it, in a manner somewhat similar to the Chaldaic arrangement of the terms. But all these imaginary attributes cannot be herein detailed, for they [Pg 37]receive no confirmation from nature, are not capable of being rationally demonstrated, and are, in fact, merely the offspring of scientific vanity.

The following observation, however, deserves attention, and must not be omitted.

The beginnings of the signs, and likewise those of the terms, are to be taken from the equinoctial and tropical points. This rule is not only clearly stated by writers on the subject, but is also especially evident by the demonstration constantly afforded, that their natures, influences and familiarities have no other origin than from the tropics and equinoxes, as has been already plainly shown.[59] And, if other beginnings were allowed, it would either be necessary to exclude the natures of the signs from the theory of prognostication, or impossible to avoid error in then retaining and making use of them; as the regularity of their spaces and distances, upon which their influence depends, would then be invaded and broken in upon.

CHAPTER XXVI

FACES, CHARIOTS, AND OTHER SIMILAR
ATTRIBUTES OF THE PLANETS

The familiarities existing between the planets and the signs are such as have been already particularised.

There are also, however, further peculiarities ascribed to the planets. Each is said to be in its proper face, when the aspect it holds to the Sun, or Moon, is similar to that which its own house bears to their houses: for example, Venus is in her proper face when making a sextile aspect to either luminary, provided she be occidental to the Sun, but oriental to the Moon, agreeably to the primary arrangement of her houses.[60]

Each planet is also said to be in its proper chariot, or throne, or otherwise triumphantly situated, when it holds familiarity with the place which it actually occupies by two, or more, of the prescribed modes of connection: for when it is so circumstanced, its influence and energy are specially augmented by the familiarity it thus holds with the sign which encompasses it, and which is similar in influence and co-operates with it.

Lastly, each planet (although it may possess no familiarity with the sign encompassing it) is said to rejoice, when any connection subsists between itself and other stars of the same condition; as, notwithstanding the distance between them, a certain sympathy and [Pg 38]communication of influence is derived from their mutual resemblance. In the same manner, again, when a planet occupies a place adverse and dissimilar in condition to itself, much of its influence is dissipated and lost; in consequence of the interposition and admixture of the other different influence, arising out of the dissimilar temperament of the sign by which it is encompassed.

CHAPTER XXVII

APPLICATION, SEPARATION, AND OTHER FACULTIES

In all cases when the distances between planets or luminaries are but trifling,[61] the planet which precedes is said to apply to that which follows; and that which follows to be separating from that which precedes.[62] The same rule obtains both in respect to bodily conjunction and to any other of the aspects before described; except that, in the application and separation of the bodily conjunction, it is also essential to observe the actual latitudes of the bodies, in order to receive and consider only such a transit as may be made in the same parts of the zodiac.[63] But in the application and separation of aspects merely, the same attention is not requisite, since all the rays are uniformly converged into one focus, that is to say, into the angle of the earth,[64] and meet there alike from every quarter.[Pg 39]

It appears, therefore, by the whole of what has been already delivered, that the effective influence of the stars must be considered as arising not only from their own peculiar natures and properties, but also from the quality of the surrounding signs, and from configuration with the Sun and the angles; all which has been pointed out. The influence of each planet, however, is strengthened chiefly when it may be oriental, swift and direct in its proper course and motion—for it has then its greatest power: but, on the other hand, it loses strength when occidental and slow in motion or retrograde; as it then acts with smaller effect.[65] Its influence also receives accession or diminution, from its position with regard to the horizon; as, if it be situated in the mid-heaven, or succedent to the mid-heaven, it is especially strong; likewise, if it be on the actual horizon, or succedent to the horizon, it is also powerful—particularly if in the eastern quarter. Should it, however, be below the earth, and configurated with the ascendant, either from the lower heaven, or from any other part below the earth, its influence then becomes more languid; but if, when below the earth, it hold no such configuration, it is entirely deprived of efficacy.[66]

[Pg 40]

BOOK THE SECOND

CHAPTER I

GENERAL DIVISION OF THE SUBJECT

The great and leading points, requiring to be attended to as a necessary means of introduction to the consideration of particular predictions, having been succinctly defined, the further parts of the subject, comprehending everything which may tend to facilitate prediction, and render it complete, shall now be duly proceeded in; and, at the same time, care shall be taken to confine the whole doctrine within the limits of natural reason.

The foreknowledge to be acquired by means of Astrology is to be regarded in two great and principal divisions. The first, which may be properly called General, or Universal, concerns entire nations, countries, or cities; and the second, denominated Particular, or Genethliacal, relates to men individually.

In considering these respective divisions, it seems proper to give priority to that which has the more general application and influence: because, in the first place, general events are produced by causes greater and more compulsatory than the causes of particular events; secondly, because natures of more extended potency must invariably control those which are more limited in action; and, thirdly, because particular events, or individual affections, are comprehended in those of general influence.[67] It is therefore especially necessary, in desiring to investigate particular events, to treat first of those which are general.

Again, general events are subdivided according to their operation upon entire countries, and upon certain cities or districts: one sub-division being regarded as affecting entire countries, and the other certain cities or districts only. They are also separately considered according to the causes by which they are produced; war, pestilence, famine, earthquakes, inundations, and other similar visitations being dependent on such greater and more important causes, as arise only after considerable periods; while slighter causes, arising more frequently, have reference only to the revolution of the seasons; their greater or less variation in cold and heat; the severity or mildness of the weather; the occasional abundance or scarcity of provisions; and other like occurrences.[Pg 41]

Hence the consideration of those events which concern whole countries, and are dependent on the greater causes (since it has a more extended scope than the other, which attaches only to certain cities, or districts, and is subject to slighter causes) takes precedence. And, for its due investigation, two essential points are to be attended to: the first is, the appropriate familiarity of the zodiacal signs and the fixed stars with the several regions which may be concerned; and the second comprises the indications occasionally arising in those parts of the heavens where such familiarity is found: for instance, the eclipses of the Sun and Moon, and such transits as may be made by the planets, when matutine, and in their respective stations.

The nature of the sympathy between these things must, however, be explained first; and a brief description will therefore be given of the chief peculiarities observable in whole nations; in regard to their manners and customs, as well as to their bodily formation and temperament; considered agreeably to their familiarity with those stars and signs whence the natural cause of their peculiarities duly proceeds.

zain n. adwan

CHAPTER II

PECULIARITIES OBSERVABLE THROUGHOUT
EVERY ENTIRE CLIMATE

The peculiarities of all nations are distinguished according to entire parallels and entire angles, and by their situation with regard to the Sun and the Ecliptic.

The climate which we inhabit is situated in one of the Northern Quadrants: but other nations, which lie under more southern parallels, that is to say, in the space between the equinoctial line and the summer tropic, have the Sun in their zenith, and are continually scorched by it. They are consequently black in complexion, and have thick and curled hair. They are, moreover, ugly in person, of contracted stature, hot in disposition, and fierce in manners, in consequence of the incessant heats to which they are exposed; and they are called by the common name of Æthiopians. But the human race does not alone afford evidence of the violent heat in these regions; it is shown also by all other animals and by the state of the surrounding atmosphere.

The natives of those countries which lie under the more remote northern parallels (that is to say, under the Arctic circle and beyond it[68]) have their zenith far distant from the zodiac and the Sun's heat. Their constitutions, therefore, abound in cold, and are also highly imbued with moisture, which is in itself a most nutritive quality, and, in these latitudes, is not exhausted by heat: hence they are fair in complexion, with straight hair, of large bodies and full stature. They are cold in disposition, and wild in manners, owing to the constant cold. The state of the surrounding atmosphere and of animals and [Pg 42]plants, corresponds with that of men; who (as natives of these countries) are designated by the general name of Scythians.

The nations situated between the summer tropic and the Arctic circle, having the meridian Sun neither in their zenith nor yet far remote from it, enjoy a well-temperated atmosphere. This favourable temperature, however, still undergoes variation, and

changes alternatively from heat to cold; but the variation is never vast nor violent. The people who enjoy this kindly atmosphere are consequently of proportionate stature and complexion, and of good natural disposition: they live not in a state of dispersion, but dwell together in societies, and are civilised in their habits. Among the nations comprehended in this division, those verging towards the south are more industrious and ingenious than the others, and more adapted to the sciences: and these qualifications are engendered in them by the vicinity of the zodiac to their zenith, and by the familiarity thus subsisting between them and the planets moving in the zodiac, which familiarly gives activity and an intellectual impulse to their minds. Again, the natives of those countries which lie towards the east excel in courage, acting boldly and openly under all circumstances; for in all their characteristics they are principally conformed to the Sun's nature, which is oriental, diurnal, masculine and dexter—(and it is plainly apparent that the dexter parts of all animals are much stronger than others)—hence results the greater courage of the inhabitants of the East. And as the Moon, on her first appearance after conjunction, is always seen in the west, the western parts are therefore lunar, and consequently feminine and sinister; whence it follows that the inhabitants of the west are milder, more effeminate and reserved.

Thus, in all countries, certain respective peculiarities exist in regard to manners, customs and laws; and in each it is found that some portion of the inhabitants differs partially and individually from the usual habits and condition of their race. These variations arise similarly to the variations perceptible in the condition of the atmosphere; as, in all countries, the general state of whose atmosphere may be either hot, or cold, or temperate, certain districts are found to possess a particular temperature of their own, and to be more or less hot, or cold, by being more or less elevated than the general face of the country. So, likewise, certain people become navigators owing to their proximity to the sea, while others are equestrian, because their country is a plain; and others, again, become domiciliated by the fertility of their soil.

And thus, in each particular climate, certain peculiar qualities are to be found, arising from the natural familiarity which it holds with the stars and the twelve signs. And although these qualities do not pervade it, in such a manner as to be necessarily exhibited by every individual native, yet they are so far generally distributed as to be of much utility in investigating particular events; and it is highly important to take at least a brief notice of them.

[Pg 43]

CHAPTER III

THE FAMILIARITY OF THE REGIONS OF THE EARTH
WITH THE TRIPLICITIES AND THE PLANETS

It has been already stated that there are four triplicities distinguishable in the zodiac. The first, composed of Aries, Leo, and Sagittarius, is the north-west triplicity; and Jupiter has chief dominion over it on behalf of its northern proportion; but Mars also rules with him in reference to the west. The second, consisting of Taurus, Virgo, and Capricorn, is the south-east; and in this triplicity Venus bears chief rule, in consequence of the southern proportion; but Saturn also governs with her in consideration of the east. The third, composed of Gemini, Libra, and Aquarius, is north-east; and Saturn is here the principal lord, in consequence of the eastern proportion; Jupiter, however, governs with him in reference to the north. The fourth triplicity is constituted of Cancer, Scorpio, and Pisces, and is south-west; it owns Mars as its principal ruler, in consideration of its western proportion; and, on behalf of the south, it is also governed by Venus.

The four triplicities being thus established, the whole inhabited earth is accordingly divided into four parts, agreeing with the number of the triplicities. It is divided latitudinally by the line of the Mediterranean Sea, from the Straits of Hercules to the

Issican Gulf, continued onwards through the mountainous ridge extending towards the east; and by this latitudinal division its southern and northern parts are defined. Its longitudinal division is made by the line of the Arabian Gulf, the Ægean Sea, Pontus, and the lake Mæotis; and by this line are separated its eastern and western parts.

Of the four quadrants of the earth, thus agreeing in number with the four triplicities, one is situated in the north-west of the entire earth, and contains Celto-galatia; or, as it is commonly called, Europe. Opposed to this quadrant lies that of the south-east, towards Eastern Æthiopia; it is called the southern part of Asia Magna. Another quadrant of the entire earth is in the north-east, about Scythia, and is called the northern part of Asia Magna. To this is opposed the quadrant of the south-west, which lies about Western Æthiopia, and is known by the general name of Libya.

Each of these quadrants contains certain parts, which, in comparison with its other parts, lie more contiguous to the middle of the earth; and these parts, in respect of the quadrant to which they belong, have a situation opposite to the rest of that quadrant, in the same manner as that quadrant itself is situated in regard to the rest of the earth. For instance, in the quadrant of Europe, which is situated on the north-west of the whole earth, those parts of it which lie towards the middle of the earth, and near the angles of the other quadrants, are [Pg 44]manifestly situated in the south-east of that quadrant. The like rule obtains in regard to the other quadrants. And hence it is evident that each quadrant is in familiarity with two oppositely-placed triplicities, its whole extent being adapted to the one triplicity which governs it as an entire quadrant; but its particular parts, situated about the middle of the earth, and lying, as regards the rest of the quadrant, in a direction contrary to that assigned to the whole quadrant altogether, being adapted to the other triplicity which rules the particular quadrant lying opposite to it. The planets exercising dominion in both these triplicities also hold familiarity with these particular parts; but, with the other more remote parts of any quadrant, only those planets hold familiarity which rule in the single triplicity to which the whole quadrant

is allotted. With the said particular parts about the middle of the earth, Mercury also, as well as the other planets in dominion, bears familiarity, in consideration of his meditative condition and common nature.

Under this arrangement, it follows that the north-western parts of the first quadrant, or that of Europe, are in familiarity with the north-west triplicity, composed of Aries, Leo, and Sagittarius; and they are accordingly governed by the lords of that triplicity, Jupiter and Mars, vespertine. These parts, as distinguished by their appropriation to entire nations, are Britain, Galatia, Germany, Barsania,[69] Italy, Apulia, Sicily, Gaul, Tuscany, Celtica, and Spain. And, since the triplicity itself and the planets connected with it in dominion are adapted to command, the natives of these countries are consequently impatient of restraint, lovers of freedom, warlike, industrious, imperious, cleanly, and high-minded. But, owing to the vespertine configuration of Jupiter and Mars, as well as the masculine condition of the anterior parts of the triplicity, and the feminine condition of its latter parts,[70] the said nations regard women with scorn and indifference.[71] They are, however, still careful of the community, brave and faithful, affectionate in their families, and perform good and kind actions.

Among the countries before named, Britain, Galatia, Germany, and Barsania have a greater share of familiarity with Aries and Mars; and their inhabitants are accordingly wilder, bolder, and more ferocious. Italy, Apulia, Sicily, and Gaul are in familiarity with Leo and the Sun; [Pg 45]and the natives of these countries are more imperious, yet kind and benevolent, and careful of the commonwealth. Tuscany, Celtica, and Spain, are connected with Sagittarius and Jupiter; and their inhabitants are lovers of freedom, simplicity, and elegance.

The south-eastern parts of this quadrant, which are situated towards the middle of the earth, viz. Thrace, Macedonia, Illyria, Hellas, Achaia, and Crete, as well as the Cyclad Isles and the shores of Asia Minor and of Cyprus, assume, in addition, a connection with the south-east triplicity, which is composed of Taurus, Virgo, and

Capricorn, and ruled by Venus and Saturn; and, in consequence of the vicinity of these regions to the middle of the earth, Mercury likewise has a proportionate dominion over them. Hence their inhabitants, being subjected to the rulers of both triplicities, enjoy a favourable temperament of mind and of body. From Mars they imbibe their fitness for command, their courage, and impatience of restraint; from Jupiter their love of freedom, their self-rule, their skill in guiding public affairs, and in legislation: through the influence of Venus they are also lovers of the arts and sciences, as well as of music and poetry, of public shows, and all the refinements of life; and from Mercury they deduce their hospitality, their fondness for society and communion, their love of equity and of literature, and their power of eloquence. They are also in the highest degree conversant with sacred mysteries, owing to the vespertine figuration of Venus.

It is further to be observed of these last-named countries, that the inhabitants of the Cyclad Isles, and of the shores of Asia Minor and of Cyprus, are more particularly under the influence of Taurus and Venus, and are therefore voluptuous, fond of elegance, and over-studious in their attention to the body. The people of Hellas, Achaia, and Crete, have a stronger familiarity with Virgo and Mercury, and are therefore learned and scientific, preferring the cultivation of the mind to the care of the body. The people of Macedonia, Thrace, and Illyria, are chiefly influenced by Capricorn and Saturn; whence they are greedy of wealth, inferior in civilization, and have no ordinances of civil polity.

The second quadrant consists of the southern division of Asia Magna. Such of its parts as are contained in India, Arriana, Gedrosia, Parthia, Media, Persia, Babylonia, Mesopotamia, and Assyria, are situated in the south-east of the whole earth, and have due familiarity with the south-east triplicity (composed of Taurus, Virgo, and Capricorn), and consequently with Venus, Mercury, and Saturn, in matutine figuration. The nature of the inhabitants of these countries is obedient to the dominion of these ruling influences; they worship Venus under the name of Isis; and they also pay devotion to Saturn, invoking him by the name of Mithranhelios. Many of them likewise

zain n. adwan

foretell future events; and they consecrate to the gods some of their bodily members, to which superstition they are induced by the nature of [Pg 46]the figuration of the planets before mentioned.[72] They are, moreover, hot in constitution, amorous and lustful, fond of acting, singing, and dancing, gaudy in their dresses and ornaments; owing to the influence of Venus. Saturn, however, inclines them to simplicity of conduct; and, in consequence of the matutine figuration, they address their women publicly.[73] There are also many among them who beget children by their own mothers.[74] The matutine figurations also influence their mode of worship, which is performed by prostration of the breast; because the heart is the nobler part of the body, and, in its vivifying faculties, acts like the Sun. And, although the influence of Venus makes the people, generally speaking, finical and effeminate in their personal adornment and apparel, yet the connection which Saturn holds with them, by means of the east, still renders them great in mind, eminent in council, courageous and warlike.

It is to be remarked, that Parthia, Media, and Persia, have a more particular familiarity with Taurus and Venus; whence it follows that the dwellers in those countries wear splendid garments, and clothe the whole person entirely, except the breast; they are also fond of elegance and refinement. The countries about Babylon, Mesopotamia, and Assyria, are connected with Virgo and Mercury; their inhabitants are consequently studious of the sciences, and, among other attainments, excel in making observations on the five planets. India, Arriana, and Gedrosia, are connected with Capricorn and Saturn; the natives of these regions are, therefore, ill-formed in person, of dirty habits, and barbarous manners.

The remaining parts of this second quadrant, viz. Idumæa, Cœlesyria, Judæa, Phœnicia, Chaldæa, Orchynia, and Arabia Felix, occupy a situation in the vicinity of the middle of the earth, and in the north-west of the quadrant to which they actually belong: hence they are in familiarity with the north-west triplicity (which consists of Aries, Leo, and Sagittarius), and they have for their rulers, Jupiter and Mars, together

with Mercury. By means of the figuration of these planets, the natives of the said countries are skilful in trade and all mercantile affairs, heedless of danger, yet treacherous, servile, and thoroughly fickle.

The inhabitants of Cœlesyria, Idumæa, and Judæa, are principally influenced by Aries and Mars, and are generally audacious, [Pg 47]atheistical,[75] and treacherous. The Phœnicians, Chaldæans, and Orchynians, have familiarity with Leo and the Sun, and are therefore more simple and humane in disposition; they are also studious of astrology, and pay greater reverence than all other nations to the Sun. The people of Arabia Felix are connected with Sagittarius and Jupiter: the country is fertile, and abundantly productive of spices, and its inhabitants are well-proportioned in person, free in all their habits of life, and liberal in all their contracts and dealings.

The third quadrant occupies the northern division of Asia Magna. Those several parts of it which lie to the north-east of the whole earth, and comprise Hyrcania, Armenia, Mantiana, Bactriana, Casperia, Serica, Sauromatica, Oxiana, and Sogdiana, are in familiarity with the north-east triplicity, composed of Gemini, Libra, and Aquarius, and have for their rulers Saturn and Jupiter, in matutine positions; hence the inhabitants worship Jupiter and the Sun.[76] They are abundantly rich in all things: they possess much gold, and are dainty and luxurious in their diet. They are also learned in theology, skilled in magic, just in all their dealings, free and noble-minded, holding dishonesty and wickedness in abhorrence, strongly imbued with the softer affections of nature; and, in a worthy cause, they will even readily embrace death to preserve their friends. They are, furthermore, chaste in marriage, elegant and splendid in their dress, charitable and beneficent, and of enlightened intellect. All these qualities are principally produced by the matutine positions of Saturn and Jupiter, who influence the region.

Among these nations, however, Hyrcania, Armenia, and Mantiana, have a greater familiarity with Gemini and Mercury; and the inhabitants are consequently more acute in apprehension, but less tenacious of their probity. The countries about Bactriana,

Casperia, and Serica, are connected with Libra and Venus; and the natives are endowed with much wealth and many luxuries, and take delight in poetry and songs. The nations about Sauromatica, Oxiana and Sogdiana, are influenced by Aquarius and Saturn; and are therefore less polished in manners, and more austere and uncouth.

The other parts of this quadrant, lying near the middle of the entire earth, consist of Bithynia, Phrygia, Colchis, Laxica, Syria, Commagene, Cappadocia, Lydia, Lycia, Cilicia, and Pamphylia. These, being situated in the south-west of their quadrant, have familiarity accordingly with the south-west triplicity, composed of Cancer, Scorpio, and Pisces, and [Pg 48]are ruled by Mars and Venus, together with Mercury. In these countries Venus is principally worshipped; she is invoked as the Mother of the Gods, and by various local and indigenous appellations; Mars likewise receives adoration here, under the name of Adonis, as well as by other titles;[77] and some of the religious services to these deities are performed by loud lamentations. The people are servile in mind, diligent in labour, yet fraudulent, knavish, and thievish; they enter into foreign armies for the sake of hire, and make prisoners and slaves of their own countrymen: besides which, they are continually subject to intestine broils. These traits arise from the matutine figurations of Mars and Venus. It is further to be observed, that, from the circumstance of Mars receiving his exaltation in Capricorn (one of the signs of the triplicity ruled by Venus), and Venus hers in Pisces (a sign belonging to the triplicity of Mars), it thence follows that the women have strong attachments and kindly affections to their husbands, are vigilant and careful in domestic affairs, and highly industrious: they also act as servants, and labour for the men, with all due obedience, in every thing.

Bithynia, Phrygia, and Colchis, must however be excepted from sharing in this general propriety of the female character; for, as these nations are chiefly connected with Cancer and the Moon, their male population is, generally speaking, slavish in its habits, timid and superstitious, while the greater part of the women, owing to the

matutine and masculine position of the Moon, are of masculine manners, ambitious of command, and warlike. These females, like the Amazons, shun the addresses of men, and delight in the use of arms, and in manly occupations: they also amputate the right breasts of their female children for the sake of adapting them to military service, and in order that, when in combat and exposing that part of their body, they may appear to be of the male sex. Again, Syria, Commagene, and Cappadocia, are principally influenced by Scorpio and Mars; and their inhabitants are accordingly bold, wicked, treacherous, and laborious. Lydia, Cilicia, and Pamphylia, have a greater familiarity with Pisces and Jupiter; when their inhabitants are wealthy, of mercantile habits, living in freedom and in community, faithful to their engagements, and honest in their dealings.

The remaining quadrant is the vast tract known by the general name of Libya. Its several parts, distinguished by the particular names of Numidia, Carthage, Africa,[78] Phazania, Nasamonitis, Garamantica, [Pg 49]Mauritania, Getulia, and Metagonitis, are situated in the south-west of the entire earth, and have due familiarity with the south-west triplicity, composed of Cancer, Scorpio, and Pisces; their rulers therefore are Mars and Venus, in vespertine position. From this figuration of the planets it results that the dwellers in these regions are doubly governed by a man and a woman, who are both children of the same mother; the man rules the males, and the woman the females. They are extremely hot in constitution, and desirous of women; their marriages are usually made by violence, and in many districts the local princes first enjoy the brides of their subjects: in some places, however, the women are common to all. The influence of Venus causes the whole people to delight in personal ornaments, and in being arrayed in female attire: nevertheless, that of Mars renders them courageous, crafty, addicted to magic, and fearless of dangers.

Again, however, of the above-named countries, Numidia, Carthage, and Africa, are more particularly in familiarity with Cancer and the Moon: their inhabitants, consequently, live in community, attend to mercantile pursuits, and enjoy abundantly

all the blessings of nature. The natives of Metagonitis, Mauritania, and Getulia, are influenced by Scorpio and Mars, and are consequently ferocious and pugnacious in the highest degree; eaters of human flesh, utterly indifferent to danger, and so regardless and prodigal of blood, as to slay each other without hesitation on the slightest cause. The people in Phazania, Nasamonitis, and Garamantica, are connected with Pisces and Jupiter, and are accordingly frank and simple in manners, fond of employment, well disposed, fond of the decencies of life, and, for the most part, free and unrestrained in their actions: they worship Jupiter by the name of Ammon.

The other parts of this quadrant, which lies near the middle of the entire earth, are Cyrenaica, Marmarica, Ægypt, Thebais, Oasis, Troglodytica, Arabia, Azania, and Middle Æthiopia. These countries, being situated in the north-east of their quadrant, have due familiarity with the north-east triplicity (consisting of Gemini, Libra, and Aquarius), and are governed by Saturn and Jupiter, and also by Mercury. Their inhabitants, therefore, participate in the influence of all the five planets in vespertine figuration, and consequently cherish due love and reverence for the gods, and dedicate themselves to their service. They are addicted to sepulchral ceremonies; and, owing to the said vespertine position, they bury their dead in the earth,[79] and remove them from the public eye. They use various laws and [Pg 50]customs, and worship divers gods. In a state of subjection, they are submissive, cowardly, abject, and most patient; but when they command, they are brave, generous, and high-minded. Polygamy is frequent among them, and practised by the women as well as the men: they are most licentious in sexual intercourse, and allow incestuous commerce between brothers and sisters. Both men and women are extraordinarily prolific, and correspond in this respect with the fecundity of their soil. Many of the men are, however, effeminate and debased in mind; in consequence of the figuration of the malefics, together with the vespertine position of Venus; and some of them mutilate their persons.[80]

Among these last-named countries, Cyrenaica, Marmarica, and particularly Lower Ægypt, are chiefly influenced by Gemini and Mercury: the natives are therefore highly intellectual and sensible, and gifted with capacity for every undertaking; above all, for the attainment of wisdom, and an insight into divine mysteries. They are also magicians, performing secret rites and ceremonies, and are in every respect calculated for the prosecution of all scientific inquiry.[81] The inhabitants of Thebais, Oasis, and Troglodytica, are connected with Libra and Venus; they are of warmer constitution, and more hasty disposition, and enjoy life in all its plentitude and abundance. The natives of Arabia, Azania, and Middle Æthiopia, have familiarity with Aquarius and Saturn; they consequently feed on flesh and fish indiscriminately, and live in a state of dispersion like wild beasts; they never unite in society, but lead a wandering and savage life.[Pg 51]

CHAPTER IV

THE FAMILIARITY OF THE REGIONS OF
THE EARTH WITH THE FIXED STARS

In addition to the rules which have been already given, respecting the familiarity of the regions of the earth with the signs and planets, it must be observed, that all fixed stars which may be posited on any line, drawn from one zodiacal pole to the other, through such parts of the zodiac as may be connected with any particular country, are also in familiarity with that particular country.

And, with regard to metropolitan cities, it is necessary to state, that those points or degrees of the zodiac, over which the Sun and Moon were in transit, at the time when the construction of any such city was first undertaken and commenced, are to be considered as sympathizing with that city in an especial manner; and that, among the angles, the ascendant is principally in accordance with it. In certain cases, however, where the date of foundation of a metropolis cannot be ascertained, the mid-heaven in the nativity of the reigning king, or other actual chief magistrate, is to be substituted, and considered as that part of the zodiac with which it chiefly sympathizes.[82]

CHAPTER V

MODE OF PARTICULAR PREDICTION IN ECLIPSES

After having gone through the necessary preliminary topics, it is now proper to speak of the manner in which predictions are to be formed and considered; beginning with those which relate to general events, affecting either certain cities, or districts, or entire countries.

zaid n. adwan

The strongest and principal cause of all these events exists in the [Pg 53]ecliptical conjunctions of the Sun and Moon, and in the several transits made by the planets during those conjunctions.

One part of the observations, required in forming predictions in cases of this nature, relates to the locality of the event, and points out the cities or countries liable to be influenced by particular eclipses, or by occasional continued stations of certain planets, which at times remain for a certain period in one situation. These planets are Saturn, Jupiter, and Mars; and they furnish portentous indications, when they are stationary.

Another branch relates to time, and gives pre-information of the period at which the event will occur, and how long it will continue to operate.

The third branch is generic; and points out the classes, or kinds, which the event will affect.

The last part is specific; and foreshows the actual quality and character of the coming event.

CHAPTER VI

THE REGIONS OR COUNTRIES TO BE CONSIDERED AS LIABLE TO BE COMPREHENDED IN THE EVENT

The first of the several branches of consideration just enumerated relates to locality, and is to be exercised in the following manner:—

In all eclipses of the Sun and Moon, and especially in such as are fully visible, the place in the zodiac, where the eclipse happens, is to be noted; and it must be seen what countries are in familiarity with that place, according to the rules laid down regarding the quadrants and the triplicities; and in like manner it must be observed what cities are

zaid n. adwan

under the influence of the sign in which the eclipse happens; either by means of the ascendant, and the situations of the luminaries at the time of their foundation, or by means of the mid-heaven of their kings or governors, actually ruling at the time of the eclipse; although such time may be subsequent to the building of the said cities. Whatever countries or cities shall be thus found in familiarity with the ecliptical place, will all be comprehended in the event; which will, however, principally attach to all those parts which may be connected with the identical sign of the eclipse,[83] and in which it was visible while above the earth.[84]

[Pg 54]

CHAPTER VII

THE TIME AND PERIOD OF THE EVENT

The second point requiring attention relates to time, and indicates the date when the event will take place, and the period during which its effect will continue: these are to be ascertained in the following manner.

It must however be premised, that as an eclipse, occurring at any particular season, cannot happen in all climates at the same temporal or solar hour,[85] so neither will the magnitude of the obscuration, nor the time of its continuance, be equal in all parts of the world. First, therefore (as is done in a nativity), the angles are to be arranged, in every country connected with the eclipse, according to the hour at which the eclipse takes place and the elevation of the pole in that country. The time, during which the obscuration of the eclipse may continue in each country, is then to be noted in equatorial hours.[86] And, after these particulars have been carefully observed, it is to be understood that the effect will endure as many years as the obscuration lasted hours, provided the

eclipse was solar; but if lunar, a like number of months is to be reckoned instead of years.

The commencement of the effect, and the period of its general intensity, or strength, are to be inferred from the situation of the place of the eclipse with respect to the angles. For, if the ecliptical place be near the eastern horizon, the effect will begin to be manifested in the course of the first four months after the date of the eclipse; and its general height, or intensity, will take place in, or about, the first third part of the whole extent of its duration. If the ecliptical place happen to be in or near the mid-heaven, the effect will begin to appear in the second four months, and its general intensity will occur about the second third part; and, if the place should fall near the western horizon, the effect will begin in the third four months, and take its general intensity in the last third part of its whole duration.[87]

[Pg 55]Partial intensities, or relaxations of the effect, are, however, to be inferred from any combinations which may happen during the intermediate period,[88] either in the actual places where the primary cause was presented, or in other places configurated therewith. They are also to be conjectured by the various courses, or transits, of such planets as co-operate in producing the effect, by being configurated with the sign in which the primary cause was situated; and, with this view, the matutine, vespertine, or stationary position, or midnight culmination of those planets must be observed; for the effect will be strengthened and augmented by their matutine or stationary position; but weakened and diminished by their being vespertine, or situated under the sunbeams, or by their midnight culmination.

CHAPTER VIII

THE GENUS, CLASS, OR KIND, LIABLE TO BE AFFECTED

The third division of these observations relates to the mode of distinguishing the genus, or species, of animals or things about to sustain the expected effect. This distinction is made by means of the conformation and peculiar properties of those signs in which the place of the eclipse, and the places of such fixed stars and planets, as are in dominion according to the actual sign of the eclipse, and that of the angle before it, may be found. And a planet, or fixed star, is to be considered as holding dominion when circumstanced as follows.

If there be found one planet having more numerous claims than any other to the place of the eclipse, as well as to that of the angle, being also in the immediate vicinity of those places, and visibly applying to, or receding from them, and having likewise more rights over other places connected with them by configuration; the said planet being, at the same time, lord by house, triplicity, exaltation, and terms; in such a case, only that single planet is entitled to dominion. But, if the lord of the eclipse and the lord of the angle be not identical, then those two planets which have most connections with each place are to be noted; and, of these two, the lord of the eclipse is to be preferred to the chief dominion, "although the other is to be considered as bearing rule conjointly."[89] And if more than two should be found, having equal preensions to each [Pg 56]place, that particular one among them which may be nearest to an angle, or most concerned with the places in question, by the nature of its condition, is to be selected for dominion.[90]

But, among the fixed stars, the chief bright one (which, during the time of the eclipse, may hold connection, in any of the nine modes of apparent configuration detailed in the First Syntaxis[91] with the angles then actually in passage), is to be admitted to dominion; as also that one which, at the ecliptical hour, may be in an eminent situation, either having risen, or having culminated with the angle following the place of the eclipse.[92]

zain.adwan

Having considered, according to the foregoing rules, what stars co-operate in regulating the coming event, the conformation and figure of the signs, in which the eclipse takes place and the said ruling stars may be posited, are also to be observed; and, from the properties and characteristics of those signs, the genus or species, to be comprehended in the event, is chiefly to be inferred.

For instance, should the zodiacal constellations, and those of the ruling fixed stars out of the zodiac, be of human shape, the effect will fall upon the human race. If the signs be not of human shape, but yet terrestrial, or quadrupedal, the event would be indicated to happen to animals of similar form: the signs shaped like reptiles signify that serpents and creatures of that description will be affected; those bearing the figure of ferocious beasts denote that the event will affect savage and destructive animals; and those figured like tame beasts show that it will operate on animals serviceable to mankind, and of domestic character; as intimated by the shape and figure of the signs, whether resembling horses, oxen, sheep, or any other useful animals. In addition to this, the terrestrial signs situated in the north, about the Arctic circle, indicate sudden earthquakes; and those in the south, sudden deluges of rain. And, should the ruling places be situated in signs shaped like winged animals, as in that of Aquila, or in others of similar form, the event will take effect on birds; and will chiefly attach to those which afford food to man. If the said [Pg 57]places should be in signs formed like creatures which swim, and in marine signs, such as Delphinus, the effect will be felt by marine animals, and in the navigation of fleets; if in river signs, such as Aquarius and Pisces, it will attach to animals living in rivers and in fresh waters: and, if in Argo, both sea and fresh-water animals will be affected by it.[93]

Again, should the ruling places be situated in tropical or in equinoctial signs, in either case alike they presignify changes in the state of the atmosphere, at the respective season to which each sign is appropriated. For example, with regard to the season of spring and the productions of the earth, if the said places should be in the sign of the

vernal equinox, they will produce an effect on the buds of the vine and fig, and of such other trees as sprout forth at that season. Should they be in the sign of the summer tropic, the event will affect the gathering and depositing of fruits; and, with respect to Ægypt in particular, it will impede the rising of the Nile. If they should be in the sign of the autumnal equinox, they foreshow that it will operate on grain and on various sorts of herbs; if in the sign of the winter tropic, on potherbs, esculent vegetables, and such birds and fishes as arrive in that season.

The equinoctial signs further indicate the circumstances liable to happen in ecclesiastical concerns, and in religious matters: the tropical signs give warning of changes in the atmosphere and in political affairs; the fixed signs, of changes in institutions and in buildings; and the bicorporeal signs show that the future event will fall alike on princes and their subjects.

Again, the ruling places situated in the east, during the time of the eclipse, signify that fruits and seeds, incipient institutions, and the age of youth, will be affected; those, which may be in the mid-heaven above the earth announce that the coming event will relate to ecclesiastical affairs, to kings and princes, and to the middle age; those in the west, that it will influence the laws, old age, and persons about to die.

The proportion liable to be affected, of that genus or kind on which the event will fall, is to be ascertained by the magnitude of the obscuration caused by the eclipse, and by the positions held by the operative stars in regard to the ecliptical place; as, in vespertine position to a solar eclipse, or in matutine position to a lunar eclipse, the said stars will most usually much diminish the effect; in opposition they render it moderate; but in matutine position to a solar eclipse, or in vespertine to a lunar, they greatly augment and extend it.[94]

[Pg 58]

CHAPTER IX

THE QUALITY AND NATURE OF THE EFFECT

The discrimination of the peculiar properties and character of the effect about to be produced, and of its good or evil nature, occupies the fourth and last division of this part of the subject.

These properties must be gathered from the power of the stars which control the ruling places, and from the contemperament created by their relative admixture with each other and with the places which they control. For, although the Sun and Moon are the acknowledged sources of all the efficacy and dominion of the stars, and of their strength or weakness, and in a certain manner regulate and command them, still, it is by the theory of the contemperament, produced by the stars in dominion, that the effect is indicated.

In order to understand the indications thus made, it is necessary to begin by attending to the following detail of the effective property of each planet—previously observing, however, that, when any circumstance is said, for the sake of brevity, to come to pass by the general influence of the five planets, their temperament, and the power and assistance they may derive from natures similar to their own, the actual continuance of their own proper constitution, or the casual combination of any analogous influence, arising from fixed stars or places in the zodiac, are all, at the same time, to be kept in view. Consequently, whenever any general remark is herein made relative to the five planets, it will likewise be necessary to bear in mind both their temperament and quality; as fully, indeed, as if the stars themselves had not been named, but only their effective quality and nature. And, it is further to be remembered, that, in every case of compound temperament, not only the combination of the planets with each other requires to be considered, but also that of such fixed stars and zodiacal places as share in the natures

zain. adwan

of the planets, by being respectively connected with them according to the familiarities already described.

Hence, when Saturn may be sole governor, he will produce disasters concomitant with cold. And, in as far as the event may apply to the human race in particular, it will induce among men lingering diseases, consumptions, declines, rheumatisms, disorders from watery humours, and attacks of the quartan ague; as well as exile, poverty, and a general mass of evils, griefs, and alarms: deaths also will be frequent, but chiefly among persons advanced in age. That part of the brute creation [Pg 59]which is most serviceable to man will likewise suffer, and be destroyed by disease; and men who make use of the animals thus diseased will be infected by them, and perish with them. The atmosphere will become dreadfully chilly and frosty, unwholesome, turbid and gloomy, presenting only clouds and pestilence. Copious and destructive storms of snow and hail will descend, generating and fostering insects and reptiles noxious to mankind. In rivers, and at sea, tempests will be frequent and general, causing disastrous voyages and many shipwrecks; and even fish will be destroyed. The waters of the sea will retire for a time, and again return and produce inundations; rivers will overflow their banks, and cause stagnant pools; and the fruits of the earth, especially such as are necessary to sustain life, will be lost and cut off by blight, locusts, floods, rains, hail, or some similar agency; and the loss will be so extensive as to threaten even famine.

Jupiter, if he should be lord alone, will thoroughly improve and benefit all things. Among mankind, in particular, this planet promotes honour, happiness, content, and peace, by augmenting all the necessaries and comforts of life, and all mental and bodily advantages. It induces also favours, benefits, and gifts emanating from royalty, and adds greater lustre to kings themselves, increasing their dignity and magnanimity: all men, in short, will share in the prosperity created by its influence. With regard to the operation of the event on brutes, those which are domestic and adapted to man's service will be multiplied and will thrive; while others, which are useless and hostile to man,

will be destroyed. The constitution of the atmosphere will be healthy and temperate, filled with gentle breezes and moisture, and favourable to fruits. Navigation will be safe and successful; rivers will rise to their just proportion; fruit and grain, and all other productions of the earth conducive to the welfare and happiness of mankind, will be presented in abundance.

Mars, when governing alone, generally causes such mischief and destruction as are concomitant with dryness. And, among mankind, foreign wars will be excited, accompanied with intestine divisions, captivity, slaughter, insurrections of the people, and wrath of princes against their subjects; together with sudden and untimely death, the consequence of these disturbances. Feverish disorders, tertian agues, and hæmorrhages will take place, and will be rapidly followed by painful death, carrying off chiefly youthful persons: and conflagration, murder, impiety, every infraction of the law, adultery, rape, robbery, and all kinds of violence will be practised. The atmosphere will be parched by hot, pestilential, and blasting winds, accompanied by drought, lightnings, and fires emitted from the sky. At sea, ships will be suddenly wrecked by the turbulence of the wind and strokes of lightning. Rivers will fail, springs will be dried up, and there will be a scarcity of water proper for food and sustenance. All the creatures and productions of the earth adapted to the use of man, [Pg 60]whether beasts, grain, or fruits, will be damaged or destroyed by excessive heat, by storms of thunder and lightning, or by violent winds; and whatever has been deposited in store will be destroyed or injured by fire, or by heat.

Venus, alone in domination, generally produces the same effects as Jupiter, yet with greater suavity and more agreeably. Glory, honour, and joy will attend mankind; happy marriages will be contracted, and the fortunate pairs will be blest with numerous children. Every undertaking will proceed prosperously, wealth will increase, and the conduct of human life will be altogether pure, simple and pious; due reverence being paid to all holy and sacred institutions, and harmony subsisting between princes and

their subjects. The weather also will be of a favourable temperature, cooled by moistening breezes; the air altogether pure and salubrious, frequently refreshed by fertilising showers. Voyages will be performed in safety, and be attended by success and profit. Rivers will be improved, and receive their adequate supply of waters; and all things valuable and useful to mankind, whether animal or vegetable, will abundantly thrive and multiply.

Mercury, if possessing dominion, is usually conjoined with one or other of the planets before-mentioned, and is conformed and assimilated to their natures; yet as, in itself, it presents a certain addition to their power, this planet increases the respective impulses of them all. And, in regard to the operation of the event on mankind, it will promote industry and skill in business; but, at the same time, thievish propensities, robberies, and plots of treachery: if configurated with the malefics, it will produce calamities in navigation, and will also cause dry and parching diseases, quotidian fever, cough, consumption, and hæmorrhage. All parts of the ceremonies and services of religion, the affairs of the executive government, as well as manners, customs, and laws, are disposed and regulated by this planet, conformably to its admixture and familiarity with each of the others. And in consequence of the dryness of its nature, arising from its proximity to the Sun, and the rapidity of its motion, it will generate in the atmosphere turbulent, sharp and varied winds, together with thunders, meteors, and lightnings, accompanied by sudden chasms in the earth, and earthquakes: by these means it not unfrequently occasions the destruction of animals and plants assigned to the service of mankind. Besides the foregoing effects, it produces, when in vespertine position, a diminution of waters, and, when matutine, an augmentation.

Each of the planets, when fully exercising its own separate and distinct influence, will properly produce the peculiar effects above ascribed to it; but should it be combined with others, whether by [Pg 61]configuration, by familiarity arising from the sign in which it may be posited,[95] or by its position towards the Sun, the coming event will

then happen agreeably to the admixture and compound temperament which arise from the whole communion actually subsisting among the influencing powers. It would, however, be a business of infinite labour and innumerable combinations, quite beyond the limits of this treatise, to set forth fully every contemperament and all configurations, in every mode in which they can possibly exist; and the knowledge of them must therefore be acquired by particular discrimination in every instance, under the guidance of the precepts of science. Yet the following additional remark must not be here omitted.

The nature of the familiarities, subsisting between the stars, lords of the coming event, and the countries or cities over which the event will extend, requires to be observed; for, should the stars be benefic, and their familiarity with the countries liable to sustain the effect be unimpeded by any opposing influence, they will then exercise the favourable energies of their own nature in a greater degree. And, on the other hand, when any obstacle may intervene to obstruct their familiarity, or when they themselves may be overpowered by some opposing influence, the advantages of their operation will be diminished. Again, should the stars, lords of the coming event, not be benefic, but injurious, their effect will be less severe, provided they may either have familiarity with the countries on which the event will fall, or be restrained by some opposing influence. If, however, they should have no such familiarity, and not be subjected to restraint by any others, endowed with a nature contrary to their own and possessing a familiarity with the countries in question, the evils which they produce will then be more violent and intense. And all these general affections, of whatever kind, whether good or evil, will be principally felt by those persons in whose individual nativities there may be found the same disposition of the luminaries (which are the most essential significators), or the same angles, as those existing during the eclipse which operates the general affection. The same remark equally applies to other persons, in whose nativities the disposition of the luminaries and of the angles may be in opposition to that existing during the eclipse. With respect to these coincidences, the partile agreement, or

opposition, of the ecliptical place of the luminaries to the place of either luminary in a nativity, produces an effect at least capable of being guarded against.[96]

[Pg 62]

CHAPTER X

COLOURS IN ECLIPSES; COMETS, AND SIMILAR PHENOMENA

In investigating general events, it is necessary further to observe the colours or hues displayed during an eclipse, either in the luminaries, or around them; in the shape of rods or rays, or in other similar forms. For, if these colours or hues should be black, or greenish, they portend effects similar to those produced by Saturn's nature; if white, to those operated by Jupiter; if reddish, to those by Mars; if yellow, to those by Venus; and if of various colours, to those by Mercury.

And, if the entire bodies of the luminaries be thus coloured, or should the hues extend over all the parts immediately circumjacent to the luminaries, it is an indication that the effects will attach to most parts of the region, or countries, with which the eclipse and its ruling places may be in familiarity. If, however, the colouring should not spread over the whole surface of the luminaries, nor over all the parts around them, but be limited to some particular quarter, then only such a portion of the said countries, as may be indicated by the situation of the visible hues, will be comprehended in the event.

It is also requisite to notice, with respect to general events, the risings or first appearances of those celestial phenomena called comets, whether presenting themselves at ecliptical times or at any other periods. They are displayed in the shape of beams, trumpets, pipes, and in other similar figures, and operate effects like those of

Mars and Mercury; exciting wars, heated and turbulent dispositions in the atmosphere, and in the constitutions of men, with all their evil consequences. The parts of the zodiac[97] in which they may be posited when they first appear, and the direction and inclination of their trains, point out the regions or places liable to be affected by the events which they threaten; and the form of the signs indicates the quality and nature of those events, as well as the [Pg 63]genus, class, or kind, on which the effect will fall. The time of their continuance shows the duration of their effect; and their position, with regard to the Sun, the period when it will commence; as, if they first appear matutine, they denote an early commencement; but, if vespertine, that it will be late and tardy.

The general and more comprehensive parts of the consideration regarding regions, countries, and cities, having now been explained, it becomes necessary to discuss certain particular points of the same consideration; that is to say, the annual occurrences which take place at certain fixed seasons, and the chief of which is that called the New Moon of the Year.

CHAPTER XI

THE NEW MOON OF THE YEAR

In every annual revolution made by the Sun, the first new Moon of the year is to be considered as the point of the commencement of his circuit; this is evident not only from its denomination, but from its virtue also.[98]

The case stands thus: In the ecliptic, which, as circle, has in fact no actual or definite beginning, the two equinoctial and the two tropical points, marked by the equator and the tropical circles, are reasonably assumed as beginnings. And to obviate any doubt as to which of these four points should preferably be considered as the primary beginning (since in the regular simple motion of a circle no part of it has any apparent precedence),

the appropriate quality naturally belonging to each of these four points has been taken into consideration by the writers on this subject. And the point of the vernal equinox has been consequently designated by them as the beginning of the year; because, from that time, the duration of the day begins to exceed that of the night, and because the season then produced partakes highly of moisture, which is always a predominant quality in all incipient generation and growth. After the vernal equinox comes the summer solstice; when the day attains its greatest length, and in Ægypt, at the same period, the rise of the Nile takes place and the Dog Star appears. Then follows the autumnal equinox, when all fruits are gathered in, and the sowing of seeds recommences anew; lastly, comes the winter solstice, when the day proceeds from its shortest duration towards its increase.

[Pg 64]Although the foregoing arrangement has been adopted by men of science to denote the commencement of the several seasons of the year, it yet seems to be more consonant to nature, and more consistent with the facts, that the combined positions of the Sun, and the new, or full, Moon, which happen when the Sun is nearest to the points above mentioned, should mark the four beginnings; and more especially if such combined positions should produce eclipses: thus, from the new or full Moon, taking place when the Sun is nearest to the first point of Aries, the spring should be dated; from that when the Sun is nearest to the first point of Cancer, the summer; from that when he is nearest to the first point of Libra, the autumn; and from that when he is nearest to the first point of Capricorn, the winter. The Sun not only produces the general qualities and constitutions of the seasons, by means of which very illiterate persons are enabled, in a certain degree, to form predictions, but he also regulates the proper significations of the signs with regard to the excitation of the winds, as well as other general occurrences, more or less subjected to occasional variation. All these general effects are usually brought about by the new or full Moon which takes place at the aforesaid points, and by the configurations then existing between the luminaries and the

planets: but there are certain particular consequences which result from the new and full Moon in every sign,[99] and from the transits of the planets; “and which require monthly investigation.”[100]

It therefore becomes necessary to explain, in the first instance, the particular natures and attributes exercised by each sign in influencing the several constitutions of the weather, as it exists at various times of the year; these natures and attributes shall now be immediately detailed. It will be recollected, that the particular properties of the planets and the fixed stars, as affecting the wind and the atmosphere, as well as the manner in which the entire signs hold familiarity with the winds and the seasons, have been already set forth.

CHAPTER XII

THE PARTICULAR NATURES OF THE SIGNS BY WHICH THE DIFFERENT CONSTITUTIONS OF THE ATMOSPHERE ARE PRODUCED[101]

The sign of Aries has a general tendency, arising from the presence of the Equinox, to promote thunder and hail. Certain of its parts, however, operate in a greater or less degree, according to the nature of the stars [Pg 65]which compose the sign: for instance, the front parts excite rain and wind; the middle are temperate; and those behind are heating and pestilential. The northern parts, also, are heating and pernicious, but the southern cooling and frosty.

The sign of Taurus, in its general character, partakes of both temperaments,[102] but is nevertheless chiefly warm. Its front parts, and especially those near the Pleiades, produce earthquakes, clouds and winds: the middle parts are moistening and cooling;

those behind, and near the Hyades, are fiery, and cause meteors and lightnings. The northern parts are temperate; the southern turbulent and variable.

Gemini, in its general tendency, is temperate; but its leading parts produce mischief by moisture; its middle parts are entirely temperate; its latter parts mixed and turbulent. The northern parts promote earthquakes and wind; and the southern are dry and heating.

Cancer is, in the whole, serene and warm, but its anterior part near the Præsepe are oppressively hot and suffocating; the middle parts are temperate, and the latter parts excite wind. And both its northern and southern parts are equally fiery and scorching.

Leo has a general tendency operative of stifling heat. The anterior parts are oppressively and pestilentially hot; yet the middle parts are temperate; and those behind are injurious by means of moisture. The northern parts produce variation and heat, and the southern moisture.

Virgo, in its general tendency, excites moisture and thunder. The front parts, however, are chiefly warm and noxious; the middle temperate; and the latter parts watery. The northern parts promote wind; the southern are temperate.

Libra has a general tendency to produce change and variation. Its front and middle parts are temperate; its hinder parts watery. The northern parts cause variable winds, and the southern are moistening and pestilential.

Scorpio, in its general character, is fiery and productive of thunder. The front parts cause snow; the middle are temperate; the latter parts excite earthquakes. Its northern parts are heating; its southern, moistening.

Sagittarius, generally, is effective of wind. The front parts are moistening; the middle temperate; and the hinder parts fiery. The northern parts promote wind, and the southern variation and moisture.[Pg 66]

zain.adwan

Capricorn's general tendency is to operate moisture. But its anterior parts are pernicious by means of heat, its middle parts are temperate, and its latter parts promote rain. Both its northern and southern parts are injurious by means of moisture.

Aquarius, in its general character, is cold and watery. The front parts are moistening; the middle temperate; and the latter parts productive of wind. The northern parts are heating; the southern cause snow.

Pisces, in its general character, is cold and effective of wind. The front parts are temperate; the middle moistening; the hinder parts highly heating. The northern parts excite wind, and the southern are watery.

CHAPTER XIII

MODE OF CONSIDERATION FOR PARTICULAR CONSTITUTIONS OF THE ATMOSPHERE

The first part of the consideration, requisite to form an estimate of the various constitutions liable to take effect in the atmosphere, applies to the general qualities pervading the several quarters of the year, and has therefore the most extended scope. In order to learn these qualities, it is necessary, in every quarter, to observe, as above directed, the new or full Moon which may happen before[103] the period of the Sun's transit through either tropical or equinoctial [Pg 67]point, whichever it may be; and to arrange the angles (as in the case of a nativity) according to the degree and hour at which the new or full Moon may be found to happen, in every latitude for which the consideration may be desired. Such planets and stars as may have dominion over the places where the said new or full Moon happens, and over the following angle, are then to be noted, in the same manner as that stated with regard to eclipses. And after these preliminary steps have been attended to, a general inference may be drawn as to the

proper qualities of the whole quarter; and the intensity or relaxation of their operation is to be contemplated from the natures of the ruling planets and stars, distinguished by the faculties they possess, and by the mode in which they affect the atmosphere.

The second part of the consideration relates to each month, and requires a similar observation of the new or full Moon first taking place on the Sun's progress through each sign: and it must be remembered, that, if a new Moon should have happened at a period nearest to the Sun's transit over the past tropical or equinoctial point, the new Moon also in each succeeding sign, until the commencement of the next quarter, are to be observed; but, if a full Moon should have so happened, then similar observation is to be made of each subsequent full Moon. The angles, also, must be duly attended to, as well as the planets and stars ruling in both the places[104]; and especially the nearest phases, applications, and separations of the planets, and their properties. The peculiar qualities of the two places, and the winds, liable to be excited by the planets themselves and by those parts of the signs in which they may be situated, are likewise to be considered; and also that particular wind, which is indicated by the direction of the Moon's ecliptical latitude. By the aid of these observations, and by weighing and comparing the existing vigour of each of the several properties and qualities, the general constitution of the atmosphere during each month may be predicted.

The third part of this consideration appertains to significations applying more minutely, and points out their force or weakness. In [Pg 68]this case, the partile configurations of the Sun and Moon, at the intermediate quarters, as well as at the new or full Moon, are to be attentively regarded; since there is a certain variation in the constitution of the atmosphere, which usually commences about three days before, and sometimes, also, about three days after the Moon has equated her course to the Sun. The configurations effected between the Moon, at each quarterly equation, and the planets, whether by the trine, sextile, or other authorized distances, are also to be observed; because the peculiar property of the change in the constitutions of the

atmosphere depends much upon such configurations, and may be accordingly perceived by considering the nature of the influence which the said configurated planets and the signs exercise over the atmosphere and the winds.

The particular quality of the weather, thus produced, will be more fully established on certain days; especially when the brighter and more efficacious fixed stars maybe near the Sun, either matutine or vespertine; as, when so posited, they most frequently convert the constitution of the atmosphere to an agreement with their own natures: and, when the Luminaries may transit any one of the angles, a similar effect is also produced. At all such positions the particular constitutions of the atmosphere are subject to variation, and thus become alternately more intense or more relaxed in their respective qualities. In this manner, by certain positions of the Moon, the flux and reflux of the sea are caused: and, when the Luminaries may be in angles, a change of the wind is produced, according to the direction of the Moon's ecliptical latitude.

Finally, in all these considerations, it must be remembered that the more general and first constituted cause takes precedence, and that the particular cause comes subsequently and secondarily: and, that the operation is in the highest degree confirmed and strengthened, when the stars, which regulate the general effects, may be also configurated towards the production of the particular effects.

CHAPTER XIV

THE SIGNIFICATION OF METEORS

In order to facilitate prognostication in minor and more limited instances, it is important to make further observation of all remarkable appearances occasionally visible around or near the Sun, Moon, and stars. And, for the diurnal state of the atmosphere, the Sun's rising should be remarked; for the nocturnal state, his setting; but

zaid n. adwan

the probable duration of any such state must be considered by reference to the Sun's configuration with the Moon; for, in most cases, each aspect, made between them, indicates the continuance of a certain state until another aspect shall take place.

Hence, the Sun, when rising or setting, if he shine clear and open, free [Pg 69]from mists, gloom, and clouds, promises serene weather. But, if he have a wavering or fiery orb, or seem to emit or attract red rays, or if he be accompanied in any one part by the clouds called parhelia, or by other reddish clouds of extended figure, in the form of long rays, he then portends violent winds, chiefly liable to arise from those parts in which the said phenomena may have shown themselves. If he should be pale or lurid, and rise or set encumbered with clouds, or surrounded by halos, he indicates storms and winds coming from the quarter of his apparent situation: and, if he be also accompanied by parhelia, or by lurid or dark rays, similar effects are also threatened from the parts where those appearances may be situated.[105]

The Moon's course is to be carefully observed, at the third day before or after her conjunction with the Sun, her opposition, and her intermediate quarters; for, if she then shine thin and clear, with no other phenomena about her, she indicates serenity; but, if she appear thin and red, and have her whole unilluminated part visible, and in a state of vibration, she portends winds from the quarter of her latitude and declination[106]: and if she appear dark, or pale and thick, she threatens storms and showers. All halos formed around the Moon should also be observed; for, if there appear one only, bright and clear, and decaying by degrees, it promises serene weather; but, if two or three appear, tempests are indicated: and, if they seem reddish and broken, they threaten tempests, with violent and boisterous winds; if dark and thick, they foreshow storms and snow; if black and broken, tempests with both winds and snow; and, whenever a greater number may appear, storms of greater fury are portended.

zain.adwan

The planets, also, and the brighter fixed stars, occasionally have halos, which indicate certain effects appropriate to their tinctures, and to the nature of the stars around which they may be situated.

The apparent magnitudes of the fixed stars, and the colours of the luminous masses among them, are likewise to be remarked: for, when the stars appear brighter and larger than usual, they indicate an excitation of the wind from that quarter in which they may be situated. The nebulous mass of the Præsepe in Cancer, and others similar to it, also require observation; as, if in fine weather they appear gloomy and [Pg 70]indistinct, or thick, they thereby threaten a fall of rain; but, if clear and in continual vibration, they announce rough gales of wind.[107]

Appearances occasionally visible in the sky, resembling the trains of comets,[108] usually indicate wind and drought; in a degree proportionate to their multitude and continuance.

Appearances, resembling shooting or falling stars, when presented in one part only, threaten a movement of wind from that part;[109] when in various and opposite parts, they portend the approach of all kinds of tempestuous weather, together with thunder and lightning. Clouds resembling fleeces of wool will also sometimes presage tempests; and the occasional appearance of the rainbow denotes, in stormy weather, the approach of serenity; in fine weather, storms. And, in a word, all remarkable phenomena, visible in the sky, universally portend that certain appropriate events will be produced, each harmonising with its proper cause, in the manner herein described.

After the forgoing brief investigation of the more limited as well as more extensive significations, regarding general events, it becomes proper to proceed to the doctrine of genethliacal prognostication, or judgments of individual nativities.

END OF BOOK II

[Pg 71]

BOOK THE THIRD

CHAPTER I

PROEM

In the preceding pages, such events as effect the world generally have been discussed in priority; because they are operated by certain principal and paramount causes, which are, at the same time, predominant over particular and minor events applicable only to the separate properties and natural peculiarities of individuals. The foreknowledge of these particular events is called Genethlialogy, or the science of Nativities.

It must be remembered that the causation, by which all effects, whether general or particular, are produced and foreknown, is essentially one and the same; for the motions of the planets, and of the Sun and Moon, present the operative causation of events which happen to any individual, as well as of those which happen generally; and the foreknowledge of both may be obtained by the several creatures and substances, subjected to the influence of the heavenly bodies, and by due attention to the changes produced in those natures, by the configurations displayed in the Ambient by the planetary motion.

Still, however, the causes of general events are greater and more complete than those of particular events; and, although it has been now stated, that one single identical power supplies both the causation and the foreknowledge of general as well as particular events, yet there does not belong to the two sorts of events a similar origin or beginning,

at which observation of the celestial configurations must be made, for prognostication. In regard to general events, the dates of origin and commencement are many and various; for all general events cannot be traced to one origin, neither is their origin always considered by means of the matter subjected to their operation, for it may be also established by circumstances occurring in the Ambient and presenting the causation. It may, in fact, almost be said that they all originate in eminent eclipses of the Luminaries, and in remarkable transits made by the stars, at various times.

Particular events, however, which concern men individually, may be traced to one origin, single as well as manifold. Their origin is single, in respect to the primary composition of the nascent man; but it is also manifold, in respect to other circumstances subsequently indicated by dispositions in the Ambient, correlative to the primary [Pg 72]origin. In all particular events, the origin, or birth, of the subjected matter itself, must, of course, be the primary origin; and, in succession thereto, the various beginnings of other subsequent circumstances are to be assumed. Hence, therefore, at the origin of the subjected matter, all the properties and peculiarities of its contemperament must be observed; and then the subsequent events, which will happen at certain periods, sooner or later, are to be considered by means of the division of time, or the scale of the ensuing years.[110]

CHAPTER II

THE CONCEPTION AND THE PARTURITION, OR BIRTH; BY WHICH LATTER EVENT THE ANIMAL QUITS THE WOMB, AND ASSUMES ANOTHER STATE OF EXISTENCE

zaid n. adwan

The actual moment, in which human generation commences, is, in fact, by nature, the moment of the conception itself; but, in efficacy with regard to subsequent events, it is the parturition or birth.

In every case, however, where the actual time of conception may be ascertained, either casually or by observation, it is useful to remark the effective influence of the configuration of the stars as it existed at that time; and, from that influence, to infer the future personal peculiarities of mind and body. For the seed will, at the very first, and at once, receive its due quality, as then dispensed by the Ambient; and, although in subsequent periods its substance is varied by growth and conformation, it will still, by the laws of nature, congregate, during its growth, only such matter as may be proper to itself, and will become more and more imbued with the peculiar property of the first quality impressed on it at the time of conception. These precepts must always be attended to, when that time can be ascertained.

But, if the time of conception cannot be precisely made out, that of the birth must be received at the original date of generation; for it is virtually the most important, and is in no respect deficient, on comparison with the primary origin by conception, except in one view only; viz. that the origin by conception affords the inference of occurrences which take effect previously to the birth, whereas the origin by birth can, of course, be available only for such as arise subsequently. And, although the birth should in strictness be called the secondary beginning, while the conception might be insisted on as the primary beginning, it is still found to be equal to the conception in its efficacy, and much more complete, although later in time. For the conception may, in fact, be said to be the generation of mere human seed, but the birth that of man himself; since the infant at its birth [Pg 73]acquires numerous qualities which it would not possess while in the womb, and which are proper to human nature alone; “such, for instance, as the particular action of the senses and the movement of the body and limbs.”[111] Besides, even if the position of the Ambient, actually existing at the birth, cannot be considered

to assist in forming and engendering the particular shape and qualities of the infant, it is nevertheless still auxiliary to the infant's entrance into the world: because nature, after completing the formation in the womb, always effects the birth in immediate obedience to some certain position of the Ambient, corresponding and sympathising with the primary position which operated the incipient formation. It is therefore perfectly admissible, and consistent with reason, that the configuration of the stars, as it exists at the time of birth, although it cannot be said to possess any share of the creative cause, should still be considered to act in signification, as fully as the configuration at the time of conception; because it has, of necessity, a power corresponding to that configuration which actually possessed the creative cause.

In speaking of the practicability of prognostication, in the commencement of this treatise, the intention of setting forth this part of the subject, now under consideration, in a scientific manner, has been already notified. The ancient mode of prediction, founded on the commixture of all the stars, and abounding in infinite complication and diversity, will therefore be passed over; and, in fact, any attempt to detail it, however accurately and minutely made, in conformity to the several precepts given in the traditions relating to it, would prove unserviceable and unintelligible: it is therefore entirely abandoned. And the doctrine, now presented, comprehending every species of event liable to happen, and explaining all the effective influences generally exercised by the stars, in their separate qualities, over every species of event, shall be delivered succinctly, and in agreement with the theory of nature.

With this view, certain places in the Ambient, regulating the formation of all inferences of the events liable to affect mankind, are appointed as a kind of mark to which the whole theory of those inferences is applied, and to which the operative powers of the stars, when holding familiarity with the said places, are in a general manner directed: in the same way as, in archery, the arrow is directed to the target. And any event, which depends on the compound temperament of many various natures and

zain.adwan

influences together, must be left to the discretion of the artist, who, like the skilful archer, must himself judge of the best mode of hitting the mark.

To proceed methodically and in due order, it is proper to commence by investigating such general events as are open to consideration, and liable to have happened, or to happen, at the actual origin by birth; [Pg 74]since, from that origin, all things necessary to be investigated may be gathered; as before stated. Yet, if a previous inquiry, by means of the primary origin by conception, should nevertheless be desired and undertaken, such an inquiry may still in some degree assist prognostication; although only in regard to properties and qualities dispensed and imbibed at the time of conception.

CHAPTER III

THE DEGREE ASCENDING

There frequently arises some uncertainty as to the precise time of birth, and some apprehensions lest it should not be accurately noted. In most cases, the actual minute of the hour, at which the birth happens, can only be ascertained by making a scientific observation, at the time, with an horoscopical astrolabe[112]; for all other instruments, employed in ascertaining the hour, are almost fallacious, although used by many persons with much care and attention. The clepsydra,[113] for instance, is subject to error, because the flow of the water will, from various causes, proceed irregularly: and the sundial is often incorrectly placed, and its gnomon often distorted from the true meridian line. To obviate the difficulty arising from the inaccuracy of these instruments, it seems highly necessary to present some method by which the actually ascending degree of the zodiac may be easily ascertained, in a natural and consistent manner.

And in order to attain this essential point, it is necessary first to set down the ordinary degree which, by the Doctrine of Ascensions,[114] is found near the ascendant at the

presumed hour. After this has been done, the new or full Moon, whichever it may be, that may take place next before the time of parturition, must be observed: and, if a new Moon, it will be necessary to mark exactly the degree of the conjunction of the two luminaries; but, if a full Moon, the degree of luminary only which may be above the earth during the parturition. After this, it must be observed what planets have dominion over the said degree: and their dominion depends always on the five following prerogatives, viz. on triplicity, house, exaltation, terms, and phase [Pg 75]or configuration[115]; that is to say, a planet, eligible to dominion, must be connected with the degree in question either by one, or more, or all of these prerogatives.

If, therefore, there may be found any one planet properly qualified in all or most of these prerogatives, the exact degree, which it occupies in that sign in which it may be posited during the parturition, is to be remarked; and it is then to be inferred that a degree of the same numerical denomination was actually ascending, at the precise time of birth, in that sign which appears, by the Doctrine of Ascensions, to be nearest to the ascendant.[116]

But when two planets, or more, may be equally qualified in the manner prescribed, it must be seen which of them may transit, during the parturition, a degree nearest in number to the ordinary degree shown by the Doctrine of Ascensions to be then ascending; and that said degree, nearest in number, is to be considered as pointing out the numerical denomination of the degree actually ascending. And when the degrees of two planets, or more, may closely and equally approximate in numerical denomination to the ordinary degree found by the Doctrine of Ascensions, the degree of that planet which possesses further claims, by connection with the angles and by its own condition, is to regulate the number of the actually ascending degree.

It must however be observed, that if the actual distance of the degree, in which the ruling planet may be posited, from the ordinary degree ascending, be found to exceed its distance from the ordinary degree of the mid-heaven; the numerical denomination,

found in the way above mentioned, is then to be considered as applicable to the actual degree in culmination; and the other angles are to be arranged in conformity therewith.[117]

CHAPTER IV

DISTRIBUTION OF THE DOCTRINE OF NATIVITIES

After due attention to the preceding instructions, the doctrine of genethliacal prognostication should be separately and distinctly considered, for the sake of order and perspicuity, in its first, second and successive divisions or heads of inquiry. It will thus be found to present a mode of investigation, at once practicable, competent and agreeable to nature.

One division is applicable only to certain circumstances established previously to the birth; as, for instance, to those which concern the [Pg 76]parents; another to circumstances, which may be established both before and after the birth; as those respecting brothers and sisters; another to circumstances actually occurring at the very time of birth, and immediately consequent thereupon: and this head of inquiry embraces various points, and is by no means simple: and the last division relates to events liable to take place after the birth, at various periods, earlier or later; and it involves a still more diversified theory.

Thus, the questions to be solved, in regard to the actual circumstances of the birth itself, are, whether the production will be male or female; twins, or even more; whether it will be monstrous; and whether it will be reared.

The questions of the periods subsequent to the birth relate first to the duration of life (which is distinct from the question of rearing), then to the shape and figure of the body,

to the bodily affections, and to injuries or defects in the members. After these, further inquiry is instituted as to the quality of the mind, and the mental affections; then, as to fortune, in regard to rank and honours as well as wealth. In succession to these, the character of the employment or profession is sought out; then, the questions relative to marriage and offspring, and to consentaneous friendship, are to be considered; then, that concerning travel; and, lastly, that concerning the kind of death which awaits the native. The question of death, although depending, in fact, upon the same influence as the question of the duration of life, seems yet to find its proper situation in being placed last in the series.

On each of the foregoing points of inquiry, the doctrine and precepts to be followed shall be thoroughly and succinctly detailed; but all idle conceits, promulgated by many persons without any foundation capable of sustaining the test of reason, shall be utterly avoided, in deference to the only true agency, which is derived from primal Nature herself. It is only upon clearly effective influences that this treatise is established: and all matters, which are open to an authorized mode of inquiry by means of the theory of the stars, and their positions and aspects with regard to appropriate places, shall be fully discussed here; but the divination by lots and numbers, unregulated by any systematic causation, must remain unnoticed.

The brief remarks, immediately following, are applicable to all cases, generally, and are now at once stated, to avoid the repetition of them under each particular division or head of inquiry.

Firstly, notice must be taken of that place in the zodiac which corresponds, according to the scheme of the nativity with the particular division of inquiry; for example, the place of the mid-heaven is adapted to questions comprised under the head of employment or profession; and the Sun’s place to those relative to the concerns of the father.

zain.adwan

Secondly, after the proper place has thus been duly ascertained, the planets holding right of dominion there, by any of the five prerogatives hereinbefore mentioned, are to be observed; and, if any [Pg 77]one planet be found to be lord by all these prerogatives, that planet must be admitted as the ruler of the event liable to happen under that particular head of inquiry. If, however, two or three planets hold dominion, that one among them, which may have most claims to the place in question, must be selected as the ruler.

Thirdly, the natures of the ruling planet and of the signs, in which itself and the place which it thus controls may severally be situated, are to be considered as indicating the quality of the event.

Fourthly, the proportionate vigour and strength, or weakness, with which the dominion is exercised, as exhibited either by the actual cosmical position of the ruling planet, or by its position in the scheme of the nativity, will point out to what extent and with what force the event will operate. And a planet is found to be cosmically powerful when in one of its own places,[118] or when oriental, or swift in course; and it is strong in the scheme of the nativity, when transiting an angle or succedent house; especially those of the ascendant, or of the mid-heaven. But it is cosmically weaker, when not in one of its own places; or when occidental, or retarded in its course; and in respect to the scheme of the nativity, it is weak when cadent from the angles.

Lastly; the general time, about which the event will take place, is to be inferred from the ruling planet's matutine or vespertine position, in regard to the Sun and the ascendant, and from the circumstance of its being situated in an angle, or a succedent house. As, if it be matutine, or in an angle, its influence operates earlier and more promptly; but, if vespertine or in a succedent house, later and more tardily. And, in reference to this point, the quadrant which precedes the Sun, and that which precedes the ascendant, together with the quadrants opposite to these, are oriental and matutine; and the other quadrants, following the former, are occidental and vespertine.

CHAPTER V

THE PARENTS

Under each head of inquiry, the proposed investigation must be entered upon in the manner mentioned in the preceding chapter: and, to proceed in due order, the circumstances relating to the parents require to be first disposed of.

In conformity with nature, the Sun and Saturn are allotted to the person of the father; and the Moon and Venus to that of the mother: and the mode in which these luminaries and planets may be found posited, with reference to each other, as well as to other planets and stars, will intimate the situation of affairs affecting the parents.

Thus, for example, the degree of their fortune and wealth will be [Pg 78]indicated by the doryphory,[119] or attendants of the luminaries. If the luminaries be accompanied (either in the same signs in which themselves are placed, or in the signs next following), by the benefics, and by such stars or planets as are of the same tendency as themselves, a conspicuous and brilliant fortune is presaged: especially, should the Sun be attended by matutine stars, and the Moon by vespertine,[120] and these stars be also well established in the prerogatives before mentioned. Likewise, if Saturn or Venus be matutine, and in proper face,[121] or in an angle, it foreshows the prosperity of either parent respectively, according to the scheme.[122] If, however, the luminaries hold no connection with the planets, and be unattended by any doryphory, the adverse fortunes of the parents, their humble state and obscurity, and then denoted; especially, if Saturn and Venus may not be favourably constituted. The parents are also subjected to a state of vicissitude, never rising above mediocrity, when the luminaries may have a doryphory of a condition or tendency foreign to their own: as, for instance, when Mars may ascend near in succession to the Sun, or Saturn to the Moon; or if the benefics be found constituted unfavourably, and not in conformity with their own natural condition

and tendency. But should the part of fortune, as shown by the scheme of the nativity, be found in a favourable position, and in consonance with the doryphory of the Sun and Moon, the estate of the parents will then remain steady and secure. If, however, the position be discordant and adverse, or if the malefics compose the doryphory, the parents' estate will be unproductive and even burthensome.

The probable duration of the lives of the parents is to be inferred by means of other configurations. And, in the case of the father, a long life is presaged, if Jupiter, or Venus, be in any mode whatever configurated with either the Sun, or Saturn; or, also, if Saturn himself make an harmonious configuration with the Sun; (that is to say, either by the conjunction, the sextile, or the trine); provided such configuration be fully and strongly established and confirmed:[123] and, when not so established and confirmed, although it does not actually denote a short life, yet it will not then equally presage a long life.[Pg 79]

If however the planets be not posited in the manner just described; and if Mars be elevated above,[124] or ascend in succession to the Sun, or to Saturn; or, even, should Saturn himself not be in consonance with the Sun, but configurated with it by the quartile or opposition, and if, when thus circumstanced, both he and the Sun should be posited in cadent houses, it is then indicated that the father is liable to infirmities; but, if in angles or succedent houses, the father will live only a short life, and suffer from various bodily injuries and diseases. The shortness of his life is particularly intimated by the position of the Sun and Saturn in the first two angles, viz. the ascendant and the mid-heaven, or in their succedent houses; and his affliction by diseases and injuries, when they may be posited in the two other angles, the western and the lower heaven, or in the houses succedent thereto. And, if Mars be aspected to the Sun in the way before-mentioned, the father will die suddenly, or receive injury in his face or eyes; but, should Mars be so aspected to Saturn, he will be afflicted with contractions of the muscles or limbs, and with fevers and disorders proceeding from inflammation and wounds; or

even death may be the consequence. And even Saturn himself, if badly configurated with the Sun, will also inflict disease and death on the father, by inducing such particular disorders as are incidental from watery humour.

The foregoing observations are applicable to the father, and those which follow must be attended to in the case of the mother.

Should the Sun be configurated, in any mode whatever, with the Moon or Venus, or, should Venus herself be harmoniously configurated with the Moon, either by the sextile, the trine, or the conjunction, the mother will live long.

If, however, Mars be succedent to the Moon and Venus, or in quartile or opposition to them, or, if Saturn be similarly aspected to the Moon only, and both of them be void of course or retrograde, or cadent, adverse accidents and disease will attend the mother; should they, on the other hand, be swift in motion and placed in angles, they portend that her life will be short, or grievously afflicted. Their position in the oriental angles, or succedent houses, particularly denotes the shortness of her life; and, in those which are occidental, her affliction. In the same manner, should Mars be thus aspected to the Moon (and should that luminary at the same time be oriental), the mother's sudden death, or some injury in her face or eyes, will be produced: and, if the Moon be then occidental, death will be occasioned by miscarriage in parturition, by inflammation, or by wounds. Such are the effects which ensue from these aspects made by Mars to the Moon; but, should he make them to Venus, death will then take place from fever, some latent disease, or sudden sickness. Saturn's aspect[125] to the Moon, when she is oriental, inflicts on the mother disease and death from extreme colds, or fevers; but, should the Moon be occidental, the danger arises from affections of the womb, or from consumption.

[Pg 80]In the investigation of all these circumstances, it is highly essential that the properties of the signs, in which are situated the stars actuating the influence, should be

also taken into consideration; and that, by day, the Sun and Venus should be principally observed; and by night, Saturn and the Moon.

If, however, after due attention has been paid to the foregoing points, a more specific inquiry still be demanded, it will then become necessary to assume the place allotted to the naternal or maternal condition, as the case may be, for an horoscope or ascendant, in order to pursue the investigation.[126] And by this means, which in this respect will answer the purpose of a nativity, all other particulars concerning the parents may be viewed succinctly; according to the general forms hereinafter given, as adapted for practice and applicable to all events.

In these and in all other cases, the mode, in which the influences are commixed, must be carefully kept in view; and it must be observed whether any particular stars possess, in themselves alone, the operative cause, or whether others share dominion with them; and it is then to be seen which among them all are more powerful, and which of them take the lead in establishing the event: so that due inference may be drawn agreeably to their several natures. And should the several stars, which may happen to be combined in dominion, be also equal in power, the diversity of their several natures, and the admixture of qualities thence arising, must then be taken into consideration; and, by fairly weighing this various admixture, the nature and quality of the future event may be apprehended.

[Pg 81]

Stars, posited separately or at a distance from each other, distribute, at their appropriate times and periods, the events operated by each: thus the earlier events are brought about by stars which are more oriental than others, and the latter events by those which are more occidental. For it is indispensably requisite that the star, under the influence of which some particular event is expected to happen, should be originally[127] connected with the place to which the inquiry, concerning that event, is allotted; and, if such connection should not have existed, no effect of any importance

can possibly be produced; because a star does not exercise a vigorous influence, unless it was fully in communication at the beginning. But, however, the time, at which the effect will take place, is further regulated by the relative distance of the star, governing the effect, from the Sun and the angles of the world, as well as by its primary position of dominion.

CHAPTER VI

BROTHERS AND SISTERS

Under this head of inquiry, a general and cursory investigation, only, can be performed; and an attempt to dive into minute particulars would be fruitless, and would prove to be merely a vain search after things not open to discovery.[128]

The place, whence inferences are drawn respecting brothers and sisters, is to be considered as being applicable only to children of the same mother, and it is consequently, agreeably to nature, presumed to be the same as the maternal place; viz. the sign occupying the mid-heaven; or, by day, that which contains Venus, and, by night, the Moon. This sign and its succedent are considered as indicative of the mother and her children, and the same place is therefore properly allotted to brothers and sisters.

[Pg 82]Hence, provided this place be configurated with the benefics, there will be several brothers and sisters: the number of them depending upon the number and positions of such benefic stars, whether in bicorporeal signs, or in signs of single form.

If, however, the malefics should be in elevation over this place, or be hostilely situated in opposition thereto, the brothers and sisters will then be few in number; and this fewness especially follows when the malefics may surround the Sun. Should the hostile configuration be presented from the other angles,[129] and, particularly, if from

the ascendant, Saturn will then represent the elder born; and Mars, by inflicting death, will diminish the total number of brothers and sisters.[130]

Again, should the stars, which promise brethren, be favourably circumstanced as to their cosmical position, the brethren will be eminent and illustrious; but humble and obscure, if the cosmical position be of an adverse nature. If, also, the malefic stars should be in elevation over those which give brethren, the life of the brethren will then be only of short duration.

Stars, constituted masculinely, represent brothers; those femininely, sisters. The more oriental stars likewise represent the elder born; and those which are more occidental, the younger.

Moreover, should the stars, which give brethren, be harmoniously configurated with that one which has dominion of the sign allotted to brethren, the brethren will be mutually friendly and affectionate; and, if an harmonious configuration be also extended, by the same planets, to the part of fortune, the brethren will live together in communion. But, if the stars, which give brethren, should, on the contrary, be in situations unconnected with each other, or be in opposition, the brethren will then live at variance, mutually practising enmity and fraud.

CHAPTER VII

MALE OR FEMALE

After the indications which regard brothers and sisters have been investigated by the foregoing rules, consonant with nature and reason, the actual native, or the person to whom the scheme of nativity is specially appropriated, demands attention; and the first and most obvious inquiry is whether the said native will be male or female.

The consideration of this question rests not on a single basis, nor can [Pg 83]it be pursued in one sole direction only: it depends, on the contrary, upon the several situations of the two luminaries and the ascendant, and upon such planets as possess any prerogatives in the places of those situations; and all these circumstances should be specially observed at the time of conception, and, in a general manner also, at that of birth.

Observation of the said three places, and of the mode in which the planets ruling them may be constituted, is wholly indispensable: it must be seen whether all, or most of them, may be constituted masculinely or femininely; and prediction must, of course, be regulated in conformity with their disposition, so observed; as tending to produce a male or female birth.

The masculine or feminine nature of the stars is to be distinguished in the manner already pointed out in the commencement of this treatise.[131] For instance, by the nature of the signs in which they are situated, by their relative position to each other, and also by their position towards the earth; as when in the east, they are masculinely disposed, and, when in the west, femininely. Their relative position to the Sun also affords guidance in distinguishing them; since, if they should be matutine, they are considered to signify the male gender; and if vespertine, the female. Thus, from the sex chiefly prevalent, as observed by these rules, that of the native may be rationally inferred.

CHAPTER VIII

TWINS

With respect to the probability of the birth of twins, or a greater number at once, the same places must be observed, as those mentioned in the preceding chapter; that is to say, the places of both luminaries and the ascendant.

When two, or all three, of the said places may be situated in bicorporeal signs, births of this kind will occur, in consequence of the combination which then arises; especially, provided all the planets, which control those places, should also be similarly circumstanced: or although only some of them be posited in bicorporeal signs, while the rest may be placed by two or more together. Because even more than twins will be born, in a case wherein all the ruling places may be in bicorporeal signs, most of the planets being, at the same time, posited in the same way, and configurated with them. The number of children, however, to be produced at the birth, is to be inferred from the planet which exercises the right of determining the [Pg 84]number[132]: and the sex or sexes are to be predicted by means of the planets in configuration with the Sun, Moon, and ascendant.

And, should the position of the heavens be arranged so that the angle of the mid-heaven, and not that of the ascendant, may be connected with the luminaries, there will, in that case, be produced, almost always, twins; and sometimes even more.

To speak, however, more particularly, three males will be born, as in the nativity of the Anactores,[133] when Saturn, Jupiter, and Mars may be configurated with the places before appointed, in bicorporeal signs; and three females, as in the nativity of the Graces, when Venus and the Moon, with Mercury femininely constituted, may be configurated in like manner. When Saturn, Jupiter, and Venus may be configurated, two males and one female will be born; as in the nativity of the Dioscuri[134]; and, when Venus, the Moon, and Mars may be so configurated, two females and one male; as in the nativity of Ceres, Core, and Liber.[135]

In cases of this kind, however, it most usually happens that the conception has not been complete, and that the children are born with some remarkable imperfections or deformities. And, in some instances, owing to a certain concurrence of events, these numerous productions are quite extraordinary and amazing.

[Pg 85]

CHAPTER IX

MONSTROUS OR DEFECTIVE BIRTHS

The same places, as those pointed out in the two chapters last preceding, are again to be considered, in inquiring into the probability of a monstrous or defective birth. For it will be found that, at a birth of this description, the luminaries are either cadent from the ascendant, or else not in any manner configurated with it; while, at the same time, the angles[136] are occupied by the malefics.

It therefore becomes necessary, when such a position of the heavens may occur at the time of birth, to observe forthwith the preceding new or full Moon[137] and its ruler; as well as the rulers of the luminaries at the said time of birth. For, if all the places, in which the rulers of the luminaries, and in which the Moon herself and Mercury may be situated, at the birth, or, if most of those places should be totally inconjunct and unconnected with the places of the said preceding new or full Moon and its ruler, the birth will then be monstrous. And if it should be further found, in addition to this absence of connection, that the luminaries may be also posited in quadrupedal or bestial signs, and the two malefics in angles, the birth will in that case not be human. And should the luminaries, when so circumstanced, be not at all supported by any benefic planet, but only by malefics, the creature born will be wholly indocile, wild, and of evil nature: if, however, they should receive support from Jupiter or Venus, the offspring will then be like that of dogs or cats, or other creatures held in religious veneration and used in worship[138]: but, if Mercury support the luminaries, it will resemble that of fowls, oxen, or swine, or, of other animals adapted to the service of mankind.

Zaid H. Adwan

When the luminaries may be in signs of human shape, while other circumstances in the scheme of the nativity may exist as before described, the creature born will then be human, or will partake of human nature, although it will still be defective in some peculiar quality. And, in order to ascertain the nature of that defect, the shape and form of the signs found on the angles occupied by the malefics, as well as of those wherein the luminaries are situated, must be taken into consideration: and, if in this instance also, no benefic planet should lend support to any one of the prescribed places, the offspring produced will be utterly void of reason, and indeed indefinable.[139] If, however, it should happen, that Jupiter or Venus [Pg 86]give support, the defect will be veiled by a specious outward appearance, similar to that of hermaphrodites, and of those persons called Harpocratiaci,[140] or others of like imperfections. And should Mercury also give support, in addition to that of Jupiter or Venus, the offspring will then become an interpreter of oracles and divinations; but, if Mercury support alone, it will be deaf and dumb,[141] although clever and ingenious in its intellect.

CHAPTER X

CHILDREN NOT REARED

The question which now remains to be considered, in order to complete the investigation of circumstances taking place simultaneously with the nativity, or immediately consequent thereon, is, whether the child, then born, will or will not be reared.

This inquiry is to be handled distinctly from that regarding the duration of life, although there is an apparent connection between them. The questions themselves are, indeed, similar; for it is much the same thing to inquire whether the child will be nurtured, or how long it will live; and the only distinction, between these two questions,

zaid n. adwan

arises from the different modes in which they are treated. For instance, the inquiry into the duration of life is to be pursued only in cases wherein there is allotted to the native some space of time, not less in duration than a solar period; that is to say, a year. Therefore, since time is also measured by smaller portions, such as months, days, and hours, and since the question, whether the native will or will not be reared, belongs to cases wherein some exuberance of evil influence threatens speedy destruction, and where life is not likely to endure throughout a whole year, the inquiry into the duration of life must consequently involve a more multifarious consideration, than that which relates to rearing; which may be at once disposed of, in a more general and summary manner.

Thus, if either of the two luminaries be in an angle, and one of the malefics be either in conjunction with that luminary, or else distant in longitude from each luminary, in an exactly equal space; so as to form the point of junction of two equal sides of a triangle, of which sides the two luminaries form the extremities, while, at the same time, no benefic star may partake in the configuration, and while the rulers [Pg 87]of the luminaries may be also posited in places belonging to, or controlled by, the malefics; the child, then born, will not be susceptible of nurture, but will immediately perish.

Should the configuration, made between the malefic planet and the luminaries, not exist precisely in the mode just mentioned; that is to say, should the said planet not be equally distant from both luminaries, so as to form the point of junction of two equal sides of a triangle; yet should it then happen that the rays of two malefics may nearly approach the places of the two luminaries, casting an injurious influence either on both, or only one of them, and if both the said malefics be together succedent, or in opposition, to the luminaries, or if one of them be succedent, and the other in opposition, or even if only one may particularly afflict one of the luminaries, then, in any such case, no duration of life will be allotted to the child: for the supremacy of the power of the

malefics extinguishes the influence favourable to human nature, and tending to prolong existence.

Mars is exceedingly pernicious when succedent to the Sun, and Saturn when succedent to the Moon. But a converse effect takes place when either of these planets may be in opposition to the Sun or Moon, or in elevation above them; for the Sun will then be afflicted by Saturn, and the Moon by Mars; and especially so, provided the said planets should have local prerogatives in the signs containing the luminaries, or in the sign on the ascendant. And, should a double opposition exist, by the circumstance of the luminaries being placed in two opposite angles, and by the two malefics being each so posited as to be equally distant from each luminary, the child will be born almost, if not quite, dead. Nevertheless, if the luminaries should be separating from, or be otherwise configurated with benefic planets, whose rays may be projected to parts preceding the said luminaries, the child will then live as many days, or hours, as there are degrees, numbered between the prorogator[142] and the nearest malefic.

If malefics should cast their rays to parts preceding the luminaries, and benefics to parts following them, the child will be abandoned at its birth; but will afterwards meet with adoption, and will live. Yet, if the malefics should be in elevation above those benefics which are thus configurated, the child, so adopted, will lead a life of misery and servitude: if, on the contrary, the benefics should be in elevation, then whoever may adopt the deserted child will supply the place of its parents. And, provided a benefic planet should either ascend with, or near in succession to the Moon, or be applying to her, [Pg 88]and one of the malefics be occidental, the child's own parents will, in that case, take it again under their protection.

Rules similar to the foregoing are to be observed, when more than one child is born; for, if any one of those planets, which may be configurated towards the production of two, or even more children, should be under the west, the children will be born half dead, or deformed, and imperfect in body. And, if the planet so situated should also be

beneath the malefics, the children will not be susceptible of nurture, or their life will be of the shortest span.

CHAPTER XI

THE DURATION OF LIFE

Of all events whatsoever, which take place after birth, the most essential is the continuance of life: and as it is, of course, useless to consider, in cases wherein the life of a child does not extend to the period of one year, what other events contingent on its birth might otherwise have subsequently happened, the inquiry into the duration of life consequently takes precedence of all other questions, as to the events subsequent to the birth.

The discussion of this inquiry is by no means simple, nor easy of execution; it is conducted in a diversified process, by means of the governance of the ruling places. And the method now about to be laid down seems, of all others, the most consonant with reason, and with nature: because the influence of the prorogatory places, as well as of the rulers of those places, and the disposal of the anæretic[143] places or stars, perform the whole operation of regulating the duration of life. Each of these influences is to be distinguished in the mode pointed out in the chapters immediately ensuing.

CHAPTER XII

THE PROROGATORY PLACES

Firstly, those places, only, are to be deemed prorogatory, to which the future assumption of the dominion of prorogation exclusively belongs. These several places

Zaid H. adwan

are the sign on the angle of the ascendant, from the fifth degree above the horizon, to the twenty-fifth degree below it; the thirty degrees in dexter sextile thereto, constituting the eleventh house, called the Good Dæmon; also the thirty degrees in dexter quartile, forming the mid-heaven above the earth; those in dexter [Pg 89]trine making the ninth house, called God; and lastly, those in opposition, belonging to the angle of the west.

Secondly, among these places, the degrees which constitute the mid-heaven are entitled to preference, as being of a more potent and paramount influence: the degrees in the ascendant are next in virtue; then the degrees in the eleventh house succedent to the mid-heaven; then those in the angle of the west; and, lastly, those in the ninth house, which precedes the mid-heaven.

No degrees under the earth are, in any manner, eligible to the dominion now in question; except such only as enter into light actually above the succedent, or, in other words, with the ascendant. And any sign, although it may be above the earth, is still incompetent to partake in this dominion, if it be inconjunct with the ascendant: hence the sign which precedes the ascendant, and constitutes the twelfth house (called that of the Evil Dæmon), is incompetent; and not only for the above reason, but also because it is cadent, and because the beams cast by the stars posited therein, towards the earth, are impaired by the thick and dark exhalations arising from the earth's vapours, which produce an unnatural colour and magnitude in the appearance of stars so posited, confusing, and in some measure annihilating, their beams.

Thus far with regard to the places of prorogation.

CHAPTER XIII

THE NUMBER OF PROROGATORS, AND
ALSO THE PART OF FORTUNE

zain.adwan

After due attention has been given to the instructions in the preceding chapter, the Sun, the Moon, the Ascendant, and the part of Fortune, are to be considered as the four principally liable to be elected to the office of prorogator; and their positions, together with those of such planets as rule in the places of their positions, are to be observed.

The part of Fortune is ascertained by computing the number of degrees between the Sun and the Moon; and it is placed at an equal number of degrees distant from the ascendant, in the order of the signs. It is in all cases, both by night and day, to be so computed and set down, that the Moon may hold with it the same relation as that which the Sun may hold with the ascendant; and it thus becomes, as it were, a lunar horoscope or ascendant.[144]

[Pg 90]Among the candidates for prorogation, as before-mentioned, by day the Sun is to be preferred, provided he be situated in a prorogatory place; and, if not, the Moon; but if the Moon, also, should not be so situated, then that planet is to be elected which may have most claims to dominion, in reference to the Sun, the antecedent new Moon, and the ascendant; that is to say, when such planet may be found to have dominion over any one of the places where these are situated, by at least three prorogatives, if not more; the whole number being five. If, however, no planet should be found so circumstanced, the Ascendant is then to be taken.[Pg 91]

By night, the Moon is to be elected as prorogator, provided, in like manner, she should be in some prorogatory place; and if she be not, the Sun: if he also be not in any prorogatory place, then that planet which may have most rights of dominion in reference to the Moon,[145] and the antecedent full Moon and the part of Fortune. But, if there be no planet claiming dominion in the mode prescribed, the Ascendant must be taken, in case a new Moon had last preceded the birth; but, if a full Moon, the part of Fortune.

If the two luminaries, and also some ruling planet of appropriate condition, should be each posited in a prorogatory place, then, provided one luminary may be found to occupy some place more important and influential than the others, that luminary must

be chosen; but should the ruling planet occupy the stronger place, and have prorogatives of dominion suitable to the conditions of both luminaries, the planet must then be preferred to either of them.[146]

CHAPTER XIV

NUMBER OF THE MODES OF PROROGATION

When the prorogator has been determined as above directed, it is also necessary to take into consideration the two modes of prorogation; one into succeeding signs, under the projection of rays, as it is called; and, when the prorogator may be in an oriental place, that is to say, in any place between the mid-heaven and the ascendant, this mode only is to be used. The other mode extends into signs preceding the prorogator, according to what is called horary proportion[147]; and, in cases when the prorogator may be situated in any place receding from the mid-heaven, or, in other words, between the mid-heaven and the angle of the west, both modes of prorogation are to be adopted.

It is next to be observed, that certain degrees are anæretic; though, in the prorogation made into signs preceding, the only degree which is strictly anæretic is that of the western horizon; and it becomes so [Pg 92]because it obscures the lord of life; while other degrees, of stars meeting with or testifying to the prorogator, both take away from and add to the aggregate amount of the prorogation, which would otherwise continue until the descension or setting of the prorogator. Of these last-mentioned degrees, however, there are none properly anæretic; since they are not borne to the prorogatory place, but, on the contrary, that place is carried to their positions.[148] In this manner the benefics increase the prorogation, but the malefics diminish it; and Mercury assists the influence of either party with which he may be configurated. The amount of the increase or diminution is indicated by the degree, in which each star, so operating, is exactly

situated; for the number of years will depend upon, and correspond with, the horary times[149] proper to each degree; and if the birth be by day, care must be taken to calculate the diurnal horary times; if by night, the nocturnal. These directions are to be understood as applicable to instances wherein the degrees in question may be in the ascendant; if farther advanced, a deduction proportionate to the distance is to be made, unless they should be on the occidental horizon, in which case there can be no remainder.

But, in the prorogation made into succeeding signs, the places of the malefics, Saturn and Mars, are anæretic, whether meeting the prorogator bodily, or by emission of rays in quartile, from either side, or in opposition: they are also sometimes anæretic, by a sextile ray, if in a sign of equal power, obeying or beholding the sign of the prorogator. And even the mere degree, in signs following, in quartile with the [Pg 93]prorogatory place, as also the degree in sextile, if badly afflicted, which is sometimes the case in signs of long ascension, and, still further, the degree in trine, if in signs of short ascension, are all anæretic: so also is the Sun's place, should the Moon be prorogatory. But, although the meetings, which occur in the course of prorogation thus made, have, respectively, some of them an anæretic, and other a preservative, power, in consequence of their occurring by means of an actual transmission to the prorogatory place[150]; yet their anæretic tendency is not always effectual, but only in cases where the places, so brought to the prorogatory place, may be badly afflicted. For should those places be situated within the terms of a benefic, the operation of their anæretic degree becomes impeded; and it will likewise be impeded, if either of the benefics should cast a ray in quartile, trine, or opposition,[151] to the said anæretic degree itself, or to some other degree near in succession, and not farther distant from it than twelve degrees, if the benefic be Jupiter; nor than eight, if Venus: the like impediment will also subsist, if both the prorogator and itsopponent[152] should be bodies,[153] and not have the same latitude.

Therefore, whenever there may be found two or more conflicting configurations, auxiliary on the one hand, and hostile on the other, due observation must be made to ascertain which party surpasses the other, in power as well as in number. The pre-eminence in number will be, of course, obvious, from the greater number[154] on one side than on the other; but, for pre-eminence in power, it must be seen whether the stars, auxiliary or hostile as the case may be, are, on the one side, in places appropriate to themselves, while they are not so on the other; and especially whether those on the one side may be oriental, and those on the other occidental. It is also to be observed, in all cases, that not any one of such stars, whether hostile or auxiliary, is to be left out of the present calculation, on account [Pg 94]of its casual position under the sunbeams.[155] This rule must be particularly attended to, because, even though the Moon be not prorogatory, the solar place itself becomes anæretic, if shackled by the simultaneous presence of a malefic, and not restored to freedom of operation by any benefic.

The number of years, depending on the distances between the prorogatory and anæretic places, cannot be always gathered simply and at once from the ascensional times[156] of each respective degree; but only in cases when the ascendant itself, or some other specific degree or body, actually ascending in the oriental horizon, may possess the prorogation. For, if it be desired to calculate agreeably to nature, every process of calculation that can be adopted must be directed to the attainment of one object; that is to say, to ascertain after how many equatorial times[157] the place of the succeeding body, or degree, will arrive at the position preoccupied at the birth by the preceding body, or degree: and, as equatorial time transits equally both the horizon and the meridian, the places in question[158] must be considered, in respect of their proportionate distances from both these; each equatorial degree[159] being taken to signify one solar year.

In conformity with the foregoing remarks, when it may happen that the prorogatory and preceding place may be actually on the oriental horizon, it will be proper to reckon, at once, the ascensional times which may intervene until the meeting of the degrees;

because, after the same number of equatorial times, the anæreta will arrive at the prorogatory place; that is to say, at the oriental horizon. Should the prorogatory place be found on the meridian, the whole number of degrees by right ascension, in which the whole intercepted arc will transit the meridian, must then be taken. And if the prorogatory place be on the occidental horizon, the number of descensions, in which every degree of the distance will be carried down (or, in other words, the number of ascensions, in which their opposite degrees will ascend), is in that case to be reckoned.[160]

[Pg 95]When, however, a prorogatory and preceding place may not be situated on any one of the three aforesaid points, but in some intermediate station, it must be observed that *other* times[161] will then bring the succeeding place to the preceding one; and *not* the times of ascension or descension, or transit of the mid-heaven, as above spoken of. For any places whatever, which have one particular position, on the same degree, in regard to the horizon and meridian, are alike and identical. This is the case, for instance, with all places lying on any one of those semicircles which are drawn through the arcs of the meridian and horizon; and each of these semicircles (all of which have position at the same equal distance from each other) marks one temporal hour[162]; and, as the time occupied in proceeding through the places[163] above described, and arriving at the same position of the horizon and meridian, is rendered unequal to and different from the time of transits in the zodiac; so, also, the transits of other spaces are made, agreeably to their position, in time again distinct from this.

There is, however, a method by which the proportion of time, occupied in the progress of a succeeding place to a prorogatory and preceding place, in whatever position, whether oriental, meridianal, or occidental, or any other, may be easily calculated. It is as follows:—

When it has been ascertained what degree of the zodiac is on the [Pg 96]mid-heaven, as also which are the preceding and succeeding degrees, the period of whose meeting

is to be calculated, the position of the preceding degree, and its distance in temporal hours from the meridian, are next to be noted; because any part of the zodiac, on becoming distant from the meridian in the same temporal hours, must fall on the same individual semicircle.[164] For ascertaining this distance, the number of ascensions, in a right sphere, found in the intermediate space between the said preceding degree and the mid-heaven, either above or under the earth, is to be divided by the number of the diurnal or nocturnal horary times of the said preceding degree: for instance, if that degree be above the earth, by its diurnal horary times; and, by its nocturnal, if it be under the earth. It is then to be discovered in what number of equatorial times the succeeding degree will be distant from the same meridian, by as many similar temporal hours as those by which the preceding degree is distant from it. And, to effect this, the hours in question must be noted, and it must first be observed, by the right ascensions again, how many equatorial times the succeeding degree, at its original position, is distant from the degree on the mid-heaven; and then it must be seen how many equatorial times it will be distant, on coming to the preceding degree's distance in temporal hours from the said mid-heaven: this will be found, by multiplying those hours by the succeeding degree's horary times; diurnal, if the future position be above the earth, and nocturnal if under; and the difference in amount, of these two distances, in equatorial times, will present the number of years inquired for.

CHAPTER XV

EXEMPLIFICATION

In order to exemplify the foregoing instructions, let the first point of Aries be supposed as the preceding place, and the first point in Gemini the succeeding; and let the latitude of the country, to which the operation relates, be such as will cause the longest day to consist of fourteen hours[165]; and where the horary magnitude of the beginning of Gemini will be about seventeen equatorial times.[166]

Let the first point of Aries be first placed on the ascendant, so that the beginning of Capricorn may be on the mid-heaven above the earth, and [Pg 97]the first point of Gemini be distant from the said mid-heaven 140 equatorial times.[167] Now, since the first point of Aries is distant six temporal hours from the mid-heaven above the earth, the times of that distance will be found, by multiplying the said six hours by the seventeen equatorial times of the horary magnitude of the first point of Gemini, to be 102.[168] The whole sum of the distance to the mid-heaven above the earth, is 148 times; and as 148 times exceed 102 by 46, the succeeding place will consequently devolve into the preceding place after 46 times (being the amount of the times of ascension of Aries and Taurus[169]); since, in this instance, the prorogatory place is established in the ascendant.

In like manner, let the first point of Aries be next placed on the mid-heaven, culminating; so that the first point of Gemini, in its first position, may be distant from the said mid-heaven 58 equatorial times.[170] Now, as it is required to bring the first point of Gemini, in its second position, to the mid-heaven, the whole distance is to be reckoned, viz. 58 times, in which Aries and Taurus pass the mid-heaven; because, again, the prorogatory place was culminating.[171]

In the same way, let the first point of Aries be descending[172]; so that the beginning of Cancer may occupy the mid-heaven, and the first point of Gemini precede the mid-heaven at the distance of 32 equatorial times.[173] Therefore, as the first point of Aries is on the west, and again distant six temporal hours from the meridian, let these six hours be multiplied by the seventeen times; which will produce 102, making the sum of the distance[174] of the first point of Gemini, at its future descension, from the meridian.[175] But, as the first point of Gemini, at its first position, was already distant from the meridian 32 times; which number 102 exceed by 70; it [Pg 98]will consequently arrive at its descension after 70 times, the amount of the excess; in which

space Aries and Taurus will have descended, and their opposite signs Libra and Scorpio arisen.[176]

Again, let the first point of Aries have another position, not in any angle,[177] but, for instance, at the distance of three temporal hours past the meridian; so that the 18th degree of Taurus may be on the mid-heaven, and the first point of Gemini be approaching the mid-heaven, at the distance of thirteen equatorial times. The seventeen times must, therefore, be again multiplied by the three hours, and the first point of Gemini, at its second position, will be found to be past the meridian, at the distance of 51 times.[178] The distance of 13 times of the first position and 51 times of the second position are then both to be taken; and they will produce 64 times. In the former instances the prorogatory place performed in the same succession; viz. occupying 46 times in coming to the ascendant, 58 in coming to the mid-heaven, and 70 in coming to the west; so that the present number of times, depending on the intermediate position between the mid-heaven and the west, and being 64, also differs from each of the other numbers, in proportion to the three hours' difference of position. For, in the other cases which proceeded by quadrants,[179] according to the angles, the times progressively differed by twelve, but, in the present case of a minor distance of three hours, they differ by six.[180]

There is, however, another method which may be used, and which is still more simple; for instance, should the preceding degree be on the ascendant, the following intermediate times of ascension,[181] between it and the succeeding degree, may be reckoned; should it be on the mid-heaven, the times of ascension must be reckoned on a right sphere; and, if it be on the west, descending, the intermediate times of descension[182] are to be reckoned. But, should the preceding degree be between any two of these angles, as, for instance, at the distance of Aries, just spoken of, the proper times for each angle must first be considered. And, since the first point of Aries was assigned a position between the two angles of the mid-heaven and the west, the proper times [Pg

99]of the distances from these angles to the first point of Gemini[183] would be found to be 58 from the mid-heaven, and 70 from the west. The distances, in temporal hours, of the preceding degree from each of these angles, are then to be ascertained; and whatever proportion these same temporal hours, contained in such distances between the said preceding degree and each angle, may bear to the temporal hours of the whole quadrant, the same proportion, out of the excess of the times of distance of one angle over those of the other, is either to be added to, or deducted from, the actual number of times of the respective angles. For instance, in the example before set forth, 70 times exceed 58 times by 12; and the preceding place was distant from the angles three equal temporal hours, which are the half of six, the number belonging to the whole quadrant. Now, three being the half of six, and 12 being the amount of the excess, the half of 12 is therefore to be taken, giving 6 to be either added to the 58 times, or subtracted from the 70: thus, in either way, producing 64, the required number of times.

If, however, the preceding place should be distant from either angle two temporal hours, which are the third part of 6, then, in that case, the third part of 12, the amount of the excess, must be taken, viz. 4: and, if the said two hours be the distance, as calculated from the mid-heaven, the said 4 times are to be added to the 58 times; but, if it be the distance from the occidental angle, the 4 times are to be subtracted from the 70.

In conformity with these rules now laid down, the amount of the times must necessarily be obtained.[184]

[Pg 100]The anæretic and critical influences of all meetings or descensions of prorogators[185] remain to be determined; beginning, in due order, with such as are accomplished in the shortest time. And whatever else may happen, by means of any affliction or assistance offered (in the manner heretofore prescribed) during the actual transit of the meeting, is also to be decided on, as well as whatever may occur through other circumstances, arising out of the ingresses taking place at the time: because,

should the places of both the significators be afflicted, and should the transit of the stars, at the then existing ingress, operate injuriously on the chief ruling places, it is then altogether probable that death will ensue;[186] and, even though one of the places[187] may be disposed favourably to human nature, the crisis will still be important and perilous; but, if both the places be so disposed favourably, some debility only, or transient malady, or hurt, will then happen. It is, however, necessary in these cases, to consider also what familiarity, or analogy, the peculiar properties of the places, thus meeting, may bear to the circumstances of the nativity.

In order to obviate the doubts which frequently arise, as to the particular star or place to which the anæretic dominion ought to be assigned, all the meetings should be duly contemplated and considered, each by each; and thus, after considering those chiefly corresponding with the events already past, and with the future events about to follow, or with the whole altogether, it will be practicable to found an observation on the equality or inequality of their influence.

CHAPTER XVI

THE FORM AND TEMPERAMENT OF THE BODY

The matters affecting and regulating the duration of life have now been disposed of; and it becomes proper to enter into further particulars, commencing, in due order, with the figure and conformation of the body; because Nature forms and moulds the body before she inspires it with a soul. In fact, the body, in its materiality, is endowed with suitable constitutional properties begotten with it, and almost apparent from its very birth; but the soul afterwards, and by degrees, develops the [Pg 101]appropriate qualities which it derives from the primary cause, and which become known much later than external attributes, and in process of time only.

In regard to the body, therefore, it is in all cases requisite to observe the oriental horizon, and to ascertain what planets may preside or have dominion over it, and also to pay particular attention to the Moon. For, from both these places,[188] and from their rulers, as well as from the natural formation and contemperament appertaining to every species of the human race, and also from the figure ascribed to those fixed stars which may be co-ascending, the conformation of the body is to be inferred. The planets possessing dominion have the chief influence, and the proper qualities of their places co-operate with them. And, in order to simplify these instructions, and as the planets are first to be treated of, each planet is individually to be considered as follows, viz.:

Saturn, when oriental, acts on the personal figure by producing a yellowish complexion and a good constitution; with black and curled hair, a broad and stout chest, eyes of ordinary quality, and a proportionate size of body, the temperament of which is compounded principally of moisture and cold. Should he be occidental, he makes the personal figure black or dark, thin and small, with scanty hair on the head; the body without hair, but well shaped; the eyes black or dark; and the bodily temperament consisting chiefly of dryness and cold.

Jupiter ruling, when oriental, makes the person white or fair, with a clear complexion, moderate growth of hair, and large eyes, and of good and dignified stature; the temperament being chiefly of heat and moisture. When occidental, he still causes a fair complexion, but not of equal clearness; and he produces long straight hair, with baldness on the forehead or on the crown of the head; and he then also gives a middle stature to the body, with a temperament of more moisture.

Mars, ascending, gives a fair ruddiness to the person, with large size, a healthy constitution, blue or grey eyes, a sturdy figure, and a moderate growth of hair, with a temperament principally of heat and dryness. When occidental, he makes the complexion simply ruddy, and the personal figure of moderate stature, with small eyes;

the body without hair, and the hair of the head light or red, and straight; the bodily temperament being chiefly dry.

Venus operates in a manner similar to that of Jupiter, but, at the same time, more becomingly and more gracefully; producing qualities of a nature more applicable to women and female beauty, such as softness, juiciness, and greater delicacy. She also peculiarly makes the eyes beautiful, and renders them of an azure tint.

Mercury, when oriental, makes the personal figure of a yellowish complexion, and of stature proportionate and well shaped, with small [Pg 102]eyes and a moderate growth of hair; and the bodily temperament is chiefly hot. If occidental, he gives a complexion white or fair, but not altogether clear; straight, dark hair, a thin and slight figure, some squint or defect in the eyes, and a long visage[189] faintly red; the temperament being chiefly dry.

The Sun and Moon, when configurated with any one of the planets, also co-operate: the Sun adds a greater nobleness to the figure, and increases the healthiness of the constitution; and the Moon, especially when holding or delaying her separation,[190] generally contributes better proportion and greater delicacy of figure, and greater moisture of temperament; but, at the same time, her influence in this latter particular is adapted to the proper ratio of her illumination; as referred to in the modes of temperament mentioned in the beginning of this treatise.[191]

Again, should the planets be matutine, and fully conspicuous,[192] they will cause the body to be large; if in their first station, they will make it strong and vigorous; if they should precede or be in advance, it will be disproportionate; if in their second station, it will be weaker, and, if vespertine, altogether mean and subservient to evil treatment and oppression. At the same time, the places of the planets,[193] as has been already said, co-operate especially in producing the shape of the personal figure, and contribute also towards the temperament.

And further, it is the general tendency of the quadrant comprised between the vernal equinox and the summer tropic to produce good complexions, advantageous stature, fine constitutions, and fine eyes; with a temperament abounding in heat and moisture. The quadrant from the summer tropic to the autumnal equinox tends to produce an ordinary complexion, proportionate stature, a healthy constitution, large eyes, a stout person, with curled hair, and a temperament abounding in heat and dryness. The quadrant from the autumnal equinox to the winter tropic causes yellowish complexions, slender, thin, and sickly persons, with a moderate growth of hair, fine eyes, and a temperament abundantly dry and cold. The other quadrant, from the winter tropic to the vernal equinox, gives a dark complexion, proper stature, straight hair on the head and none on the body, a goodly figure, and a temperament abounding in cold and moisture.[Pg 103]

To speak, however, more particularly, all constellations of human form, both those within and those without the zodiac, act in favour of giving a handsome shape to the body, and due proportion to the figure; while those not of human form vary its due proportions, and incline it towards their own shape; assimilating it, in some measure, to their own peculiarities, either by enlarging or diminishing its size, by giving it additional strength or weakness, or by otherwise improving or disfiguring it. Thus, for example, Leo, Virgo, and Sagittarius enlarge the person; and Pisces, Cancer, and Capricorn tend to make it diminutive; and thus, again, the upper and anterior parts of Aries, Taurus, and Leo increase its strength and their lower and posterior parts render it weaker: while, on the other hand, Sagittarius, Scorpio, and Gemini act conversely; for their anterior parts produce greater debility, and their posterior parts greater vigour. In like manner, Virgo, Libra, and Sagittarius contribute to render the person handsome and well-proportioned; and Scorpio, Pisces, and Taurus incline it to be misshapen and disfigured.

The other constellations[194] also operate on similar principles; and all these influences it is necessary to bear in mind, in order that the peculiar properties, observed

in their joint temperament, may be so compounded as to authorize an inference therefrom, concerning the form and temperament of the body.

CHAPTER XVII

THE HURTS, INJURIES, AND DISEASES OF THE BODY

Next in succession to the foregoing chapter, the circumstances relating to bodily hurts, injuries, and diseases, claim to be discussed; and they require to be considered in the following mode.

For the investigation of these circumstances, the two angles on the horizon, both the ascendant and the western, must in all cases be remarked; but more especially the western angle and its preceding house,[195] which is inconjunct with the ascendant. After these angles have been noted, it must be observed in what manner the malefic planets may be configurated with them: for, if both the malefics, or even if one of them, should be stationed bodily on any of the successive degrees composing the said angles, or be configurated with such degrees in quartile or in opposition, some bodily disorders or injuries will attach to the native or person then born: and this will especially happen if, also, both the luminaries, either together or in opposition, or even if one of them, should be angularly posited in the manner [Pg 104]described. Because, in such a case, not only a malefic which may have ascended in succession to the luminaries, but also any one which may have pre-ascended, if placed in an angle, has power to inflict certain diseases and injuries, such as may be indicated by the places of the horizon and of the signs, as well as by the natures of the planets themselves; whether malefics, or others evilly afflicted and configurated with them.

Such parts of the signs, as contain the afflicted part of the horizon, will show in what part of the body the misfortune will exist, whether it be a hurt, or disease, or both: and

the natures of the planets, in operating the misfortune, also regulate its particular form or species. For, among the chief parts of the human body, Saturn rules the right ear, the spleen, the bladder, the phlegm, and the bones; Jupiter governs the hand, the lungs, the arteries, and the seed; Mars, the left ear, the kidneys, the veins, and the privities; the Sun rules the eyes, the brain, the heart, the sinews or nerves, and all the right side; Venus, the nostrils, the liver, and the flesh; Mercury, the speech, the understanding, the bile, the tongue, and the fundament; and the Moon governs the palate, the throat, the stomach, the belly, the womb, and all the left parts.

It generally happens that some casual hurt, or injurious affection of the body, is the utmost that takes effect when the malefics may be oriental, and that considerable diseases occur only when the malefics may be occidental. And a hurt is distinct from a disease, inasmuch as the pain, which it induces at the time, is not afterwards continued; while a disease is, on the other hand, imposed on the sufferer either constantly or at repeated intervals. These remarks are applicable to all cases; but, in order to inquire particularly into the nature of the hurt or disease, a further attention must be paid to the figures, or schemes, with which the effects, about to be produced, will for the most part correspond in character.

For instance, blindness of one eye will ensue, when the Moon may be in the before-mentioned angles, either operating her conjunction, or being at the full: it will also happen should she be configurated with the Sun in any other proportional aspect, and be at the same time connected with any one of the nebulous collections in the zodiac; such as the cloudy spot of Cancer, the Pleiades of Taurus, the arrow-head of Sagittarius, the sting of Scorpio, the parts about the mane of Leo, or the urn of Aquarius. Moreover, both eyes will be injured should the Moon be in an angle, and in her decrease, and Mars or Saturn, being matutine, ascend in succession to her; or, again, if the Sun be in an angle, and these planets pre-ascend before him, and be configurated with both luminaries, whether the luminaries be in one and the same sign, or in opposition;

provided also the said planets, although oriental of the Sun, be occidental of the Moon. Under these circumstances, therefore, Mars will cause blindness by a stroke or blow, or by the sword or by burning; and, if he be configurated with [Pg 105]Mercury, it will be effected either in a place of exercise or sport, or by the assault of robbers. Saturn, however, under the same circumstances, produces blindness by cataract, or cold, by a white film, or by other similar disorders.

Venus, if in one of the angles before-mentioned, and especially if she be in that of the west, and Saturn be in conjunction or in configuration with her, or be changing place with her,[196] while Mars, at the same time, is in elevation above her, or in opposition to her, will produce impotence in the native, if a male; and, if a female, will render her liable to abortion, or to produce children stillborn, or not capable of being extracted except in mangled parts. Such misfortunes especially happen under Cancer, Virgo, and Capricorn; even though the Moon may be in the ascendant, in conjunction with Mars. And if, under the same circumstances, Venus be also configurated with Mercury, as well as Saturn, Mars again being in elevation above her, or in opposition to her, the native will be either an eunuch or hermaphrodite, or devoid of the natural channels and vents. And, when these positions occur, should the Sun also partake in the configuration, the luminaries and Venus being all masculinely constituted, the Moon in her decrease, and the malefics brought up in the degrees next successively ascending, the males will be born maimed or crippled, or injured in their private members (particularly under Aries, Leo, Scorpio, Capricorn, and Aquarius); and the females will remain childless and unprolific. And it also occasionally happens that the natives, under such a configuration, are likewise injured in the face or eyes.

If Saturn and Mercury, in conjunction with the Sun, be in the before-mentioned angles, the native will have some defect in the tongue, and stammer or speak with difficulty: especially if Mercury be occidental, and both he and Saturn configurated with the Moon. Should Mars, however, be found together with them, he will for the

most part remove the defect in the tongue, after the Moon shall have completed her approach to him.

Further, should the malefics be in angles, and the luminaries, either together or in opposition, be brought up to them; or, if the malefics be brought up to the luminaries, especially when the Moon may be in her nodes, or in her bend,[197] or in obnoxious signs, such as Aries, Taurus, Cancer, Scorpio, and Capricorn, the body will then be afflicted with excrescences, distortions, lameness or paralysis.

If the malefics be in conjunction with the luminaries, the calamity will take effect from the very moment of birth: but should they be in the mid-heaven, in elevation above the luminaries, or in opposition to each other, it will then arise out of some great and dangerous accident; [Pg 106]such as a fall from some height or precipice, an attack of robbers, or of quadrupeds. And thus, if Mars hold dominion, he will produce the misfortune by means of fire or wounds, through quarrels, or by robbers; and if Saturn, it will be caused by a fall, by shipwreck, or by convulsive fits or spasms.

The minor bodily disorders mostly occur on the Moon's being posited in a tropical or equinoctial sign; and, if in that of the vernal equinox, these disorders usually arise from the white leprosy; in that of the summer tropic, from tetters; in that of the autumnal equinox, from leprosy; and in that of the winter tropic, from the eruption of pimples, and similar inconveniences.

Considerable diseases, however, take effect when the malefics may be configurated in the same situations as those before prescribed, yet differing in one respect; that is to say, being occidental of the Sun and oriental of the Moon. In such cases, Saturn will generally produce cold in the bowels, excessive phlegm, rheumatism, emaciation, sickliness, jaundice, dysentery, cough, obstruction, colic, or scurvy; and, in women, besides these diseases, he produces complaints of the womb. Mars will cause expectoration of blood, atrabilarious attacks, pulmonary complaints, sores, and diseases in the private parts (which will be rendered still more painful by surgical burning or

incision), such as fistula, hæmorrhoids, or knots in the fundament, and also inflamed and putrifying ulcers. In women, to these calamities, he adds abortion, excision of the fœtus or its mortification.

And, even though these planets should not be properly configurated towards the particular parts of the body, their qualities will still operate. Mercury also will act with them, and contribute to the increase of the evil: thus, if he be in familiarity with Saturn, he will much augment the coldness, and promote the continuance of rheumatism, and the disturbance of the fluids; especially in the chest, throat, and stomach. If in familiarity with Mars, he will tend to produce greater dryness, and will increase ulcers, abscesses, loss of hair, scarified sores, erysipelas, tetters, blackness of bile, insanity, epilepsy,[198] and similar disorders.

Some of the properties, peculiar to disease, arise out of the various character of the signs which may contain the above mentioned configurations in the two angles. Thus Cancer, Capricorn, and Pisces, and, in short, all signs ascribed to terrestrial animals and fishes, appropriately cause diseases of putridity, tetters, excoriation, scrofula, fistula, leprosy, and the like; while Sagittarius and Gemini produce disease by falling fits and epilepsy. And if the planets happen to be posited in the latter degrees of the signs containing them, the [Pg 107]extremities of the body will then be chiefly affected by the disease or hurt; which will arise from humours or accidents, producing leprosy, gout, or other infirmities, in the hands and feet.

Under the circumstances above detailed, the disease or hurt will be incurable, provided there shall be not one of the benefics in configuration with the malefics which effect the evil, nor with the luminaries posited in angles; and even though the benefics may be so configurated, the misfortune will still be incapable of remedy, if the malefics be well fortified, and in elevation above them.

Should the benefics, however, hold principal situations, and be in elevation above the obnoxious malefics, the disease or hurt will then be moderate, and have neither

deformity nor disgrace attached to it; and it will sometimes be altogether prevented and set aside, if the benefics be oriental. Jupiter, for instance, by means of human aid, such as wealth or rank can command, will conceal and soothe hurts and diseases; and, if Mercury be joined with him, the assistance will be further improved by the addition of skilful physicians and good medicine. Venus, likewise, through the mediation of deities and oracles, will cause hurts to appear in a manner neither ungraceful nor unbecoming, and will ameliorate diseases by medicines granted by the gods.

Lastly, should Saturn be present in the configuration, the afflicted persons will move abroad to show their maladies, and to complain; and if Mercury also be present, they will do so for the sake of deriving support and profit from the exhibition.

CHAPTER XVIII

THE QUALITY OF THE MIND

The consideration of circumstances applicable to the body is practised under the foregoing rules.

Of the spiritual qualities, however, all those which are national and intellectual are contemplated by the situation of Mercury; while all others, which regard the mere sensitive faculties, and are independent of reason, are considered rather by other luminaries of a less subtle constitution and more ponderous body; for instance, by the Moon and such stars as she may be configurated with, as well by separation,[199] as by application.

Now the mind is liable to impulse in a multiplicity of directions, and the investigation of them cannot be summarily nor hastily performed, but must be conducted by means of many various observations: for the [Pg 108]different qualities of

the signs, containing Mercury and the Moon, or such stars as hold any influence over those two, are well competent to contribute towards the properties of the mind; so likewise are the configurations made with the Sun and the angles, by stars bearing any relation to the point in question; besides, also, the peculiar nature exercised by each star in operating upon the mental movements.

Thus, the tropical signs generally dispose the mind to enter much into political matters, rendering it eager to engage in public and turbulent affairs, fond of distinction, and busy in theology; at the same time, ingenious, acute, inquisitive, inventive, speculative, and studious of astronomy and divination.

Bicorporeal signs render the mind variable, versatile, not easy to be understood, volatile, and unsteady; inclined to duplicity, amorous, wily, fond of music, careless, full of expedients, and regretful.[200]

Fixed signs make the mind just, uncompromising, constant, firm of purpose, prudent, patient, industrious, strict, chaste, mindful of injuries, steady in pursuing its object, contentious, desirous of honour, seditious, avaricious, and pertinacious.

Oriental positions, and those in the ascendant, especially if made by planets in their proper faces,[201] make men liberal, frank, self-confident, brave, ingenious, unreserved, yet acute. Oriental stations, and positions on the mid-heaven, or culminations, make men reflective, constant, of good memory, firm, prudent, magnanimous, successful in pursuing their desires, inflexible, powerful in intellect, strict, not easily imposed upon, judicious, active, hostile to crime, and skilful in science.

Precedent and occidental positions make men unsteady, irreverent, imbecile, impatient of labour, easily impressed, humble, doubting, wavering, boastful, and cowardly, slothful, lazy, and hard to rouse. Occidental stations, and positions on the lower heaven (as well as Mercury and Venus, when making vespertine descension by day, and rising in the night), will render the mind ingenious and sagacious, but not

capable of great recollection, nor very industrious; yet inquisitive in occult matters, such as magic and sacred mysteries; also studious of mechanics, and mechanical instruments: addicted to the observation of meteors, to philosophy, to augury by means of birds, and to the judgment of dreams.

Further, should the planets having dominion be in places of their own, and in conditions suitable to their own qualities, the mental properties will be rendered exquisite, unimpeded, and successful: and especially if these planets rule at the same time over both places; that is to say, be by some mode configurated with Mercury, and holds [Pg 109]separation from, or application to the Moon. Should the said planets, however, not be thus constituted, but be posited in places not particularly appropriate to themselves, they will yet, even then, infuse into the composition of the mental energy the properties of their own nature; but obscurely and imperfectly, and not with such force and strong evidence as in the other case.

The peculiar qualities of planets in dominion, or in elevation, are powerfully impressed upon the mental energy: for instance, persons, who, in consequence of the familiarity of the malefics, become wicked and dishonest, have their impulse to commit evil, free and unrestrained, when the said familiarity is not governed by any contrary influence. But, should a contrary condition impede and govern that familiarity, the impulse will be frustrated, and the culprits will be easily overtaken, and undergo punishment. In like manner, persons endowed with goodness and virtue, by the familiarity between the benefics and the before-mentioned places,[202] and when no contrary influence in elevation may interpose, will exert themselves with cheerfulness and alacrity in performing good actions, will be subject to no injustice, but enjoy the advantages of their honesty and virtue. If, however, this familiarity should be superseded by some contrary condition, the very mildness and humanity of these persons will operate to their disadvantage, exposing them to contempt and accusation, and rendering them liable to be wronged by the multitude.

zain.adwan

The foregoing observations, relative to the moral habit, apply generally; and the particular properties, created in the mental energies by the actual nature of the planets, according to the respective dominion of each, remain to be treated of.

The planet Saturn, therefore, when alone possessing dominion of the mind, and governing Mercury and the Moon, and if posited in glory, both cosmically and with respect to the angles,[203] will make men careful of their bodies,[204] strong and profound in opinion, austere, singular in their modes of thinking, laborious, imperious, hostile to crime, avaricious, parsimonious, accumulators of wealth, violent, and envious: but, if he be not in glory, cosmically, and as regards the angles, he will debase the mind, making it penurious, pusillanimous, ill-disposed, indiscriminating, malignant, timorous, slanderous, fond of solitude, repining, incapable of shame, bigoted, fond of labour, void of natural affection, treacherous in friendship and in family connections, incapable of enjoyment, and regardless of the body.[205] Connected with Jupiter in the mode before-mentioned, being also situated [Pg 110]in glory, Saturn will render the mind virtuous, respectful, well-intentioned, ready to assist, judicious, frugal, magnanimous, obliging, solicitous of good, affectionate in all domestic ties, mild, prudent, patient, and philosophical: but, if thus connected and posited ingloriously, he makes men outrageous, incapable of learning, timorous, highly superstitious, yet regardless of religion, suspicious, averse to children, incapable of friendship, cunning, misjudging, faithless, foolishly wicked, irascible, hypocritical, idle and useless, without ambition, yet regretful, morose, highly reserved, over-cautious, and dull. Conciliated with Mars, and posited in glory, Saturn renders men reckless, over-diligent, free in speech, turbulent, boastful, austere in their dealings, pitiless, contemptuous, fierce, warlike, bold, fond of tumults, insidious, deceitful, and implacable; promoters of faction, tyrannical, rapacious, hostile to the commonwealth, delighting in strife, vindictive, profound in guilt, strenuous, impatient, insolent, mischievous, overbearing, evil, unjust, obstinate, inhuman, inflexible, immutable in opinion, busy, able in office,

active, submitting to no opposition, and on the whole successful in their undertakings; but, if thus connected, and not placed in glory, he will make men plunderers, robbers, adulterers, submissive to evil, seeking gain by their turpitude, infidels in religion, void of the common affections, mischievous, treacherous, thievish, perjurers, and sanguinary; eaters of unlawful food, familiar with guilt, assassins, sorcerers, sacrilegious, impious, violators of the tomb, and, in short, thoroughly depraved. Conciliated with Venus, and being again in glory, Saturn makes men averse to women, and renders them fond of governing, prone to solitude, highly reserved, regardless of rank, indifferent to beauty, envious, austere, unsociable, singular in opinion, addicted to divination and to religious services and mysteries; solicitous of the priesthood, fanatical, and subservient to religion; solemn, reverential, sedate, studious of wisdom, faithful in friendship, continent, reflective, circumspect, and scrupulous in regard to female virtue: but, if he be thus conciliated, and not posited in glory, he makes men licentious and libidinous, practisers of lewdness, careless, and impure in sexual intercourse; obscene, treacherous to women, especially to those of their own families; wanton, quarrelsome, sordid, hating elegance; slanderous, drunken, superstitious, adulterous, and impious; blasphemers of the gods, and scoffers at holy rites; calumniators, sorcerers, hesitating at nothing. If conciliated with Mercury, and if in a glorious position, Saturn makes men inquisitive, loquacious, studious of law and of medicine, mystical, confederate in secrecy, fabricators of miracles, impostors, improvident, cunning, familiar with business, quick in perception, petulant, accurate, vigilant, meditative, fond of employment, and tractable: but, if connected with Mercury, and not posited gloriously, he causes men to be frivolous, vindictive, laborious, alienated from their families, fond of tormenting, and void of enjoyment; night-wanderers, insidious, [Pg 111]treacherous, pitiless, and thievish; magicians, sorcerers, forgers of writings, cheats, unsuccessful in their undertakings, and quickly reduced to adversity. Such are the effects of Saturn.

When Jupiter alone has dominion of the mind, and is gloriously situated, he renders it generous, gracious, pious, reverent, joyous, courteous, lofty, liberal, just, magnanimous, noble, self-acting, compassionate, fond of learning, beneficent, benevolent, and calculated for government: and, if posited ingloriously, he will endow the mind with qualities apparently similar to these, but not of such virtue and lustre: as, instead, of generosity, he will then cause profusion; instead of piety, bigotry; for modesty, timidity; for nobleness, arrogance; for courteousness, folly; for elegance, voluptuousness; for magnanimity, carelessness; and for liberality, indifference. Conciliated with Mars, and being in glory, Jupiter will make men rough, warlike, skilful in military affairs, dictatorial, refractory, impetuous, daring, free in speech, able in action, fond of disputation, contentious, imperious, generous, ambitious, irascible, judicious, and fortunate: but, if thus connected, and not placed in glory, he makes men mischievous, reckless, cruel, pitiless, seditious, quarrelsome, perverse, calumnious, arrogant, avaricious, rapacious, inconstant, vain and empty, unsteady, precipitate, faithless, injudicious, inconsiderate, senseless, and officious; inculpators, prodigals, triflers, altogether without conduct, and giving way to every impulse. When conciliated with Venus, and in a glorious position, Jupiter will render the mind pure, joyous, delighting in elegance, in the arts and sciences, and in poetry and music; valuable in friendship, sincere, beneficent, compassionate, inoffensive, religious, fond of sports and exercises, prudent, amiable, and affectionate, gracious, noble, brilliant, candid, liberal, discreet, temperate, modest, pious, just, fond of glory, and in all respects honourable and worthy; but, if posited ingloriously, when so connected, he makes men luxurious, soft, effeminate, fond of dancing, indulgent in expenses, incapable of managing women, yet amorous and lascivious; mean, slanderous, adulterous, fond of dress, dissolute, dull, wasteful, without energy, enervated, fond of personal adornment, womanish in mind, yet observant of holy rites and ceremonies, faithful, harmless, pleasant, affable, cheerful, and liberal to misfortune. If connected with Mercury, and posited in glory, Jupiter will render men fit for much business, fond of learning, and of geometry and the

mathematics; poetical, public orators, acute, temperate, well-disposed, skilful in counsel, politic, beneficent, able in government, pious, religious, valuable in all useful professions, benevolent, affectionate in their families, ready in acquiring knowledge, philosophical, and dignified: but when so connected, and placed ingloriously, he will produce contrary effects, rendering men frivolous, empty, contemptible, credulous of falsehood, senseless, fanatical, trifling, petulant, affectors of wisdom, stupid, arrogant, pretenders in art, magicians, and vacillating: Yet he will [Pg 112]also produce men skilled in various learning, and of strong memory, capable of imparting instruction, and pure in their enjoyments.

Mars alone having dominion of the mind, and placed with glory, makes men noble, imperious, irascible, warlike, versatile, powerful in intellect, daring, bold, refractory, careless, obstinate, acute, self-confident, contemptuous, tyrannical, strenuous, stern and able in government: but, posited ingloriously, he makes men cruel, mischievous, sanguinary, tumultuous, extravagant in expense, boisterous, ruffian-like, precipitate, drunken, rapacious, pitiless, familiar with crime, restless, outrageous, hostile to their families, and infidels in religion. Should he be conciliated with Venus, and posited in glory, he renders the mind cheerful, docile, friendly, complacent, joyous, playful, frank, delighting in songs and dancing, amorous, fond of the arts, and of dramatic personation, voluptuous, brave, libidinous in desire, sensible, cautious, and discreet; disposed to free sexual intercourse,[206] quick in anger, extravagant in expense, and jealous: but, if he have an inglorious position when thus conciliated, he makes men overbearing, lascivious, sordid, opprobrious, adulterous, mischievous, liars, fabricators of deceit, cheats of their own families as well as others, eager in desire, and at the same time soon satiated, debauchers of wives and virgins, daring, impetuous, ungovernable, treacherous, faithless, dangerous, fickle and weak in mind; and occasionally also wasteful, fond of dress, audacious, and shameless. Connected with Mercury, and placed in glory, Mars renders men skilful in command, cautious, strenuous, active, obstinate,

yet versatile, inventive, sophistical, laborious, busy in all things, eloquent, imposing, deceitful, inconstant, overknowing, maliciously artful, quick witted, seductive, hypocritical, treacherous, habituated to evil, inquisitive, fond of strife, and successful; fair dealers with persons of habits similar to their own, and, in short, altogether mischievous to their enemies, though beneficial to their friends: but, if Mars be posited ingloriously, and thus connected, he makes men prodigal, yet avaricious, cruel, daring, bold, regretful and vacillating; liars, thieves, infidels in religion, perjurers, and impostors; seditious, incendiaries, frequenters of theatres, covered with infamy, robbers, housebreakers, sanguinary, forgers of writings, familiar with crime, jugglers, magicians, sorcerers, and assassins.

When Venus rules alone in a position of glory, she renders the mind benignant, good, voluptuous, copious in wit, pure, gay, fond of dancing, jealous, abhorring wickedness, delighting in the arts, pious, modest, well-disposed, happy in dreams, affectionate, beneficent, compassionate, refined in taste, easily reconciled, tractable, and entirely amiable: but, if contrarily posited, she renders the mind dull, amorous, effeminate, timorous, indiscriminating, sordid, faulty, obscure, and ignominious. Conciliated with Mercury, and posited with [Pg 113]glory, Venus makes men lovers of the arts, philosophical, of scientific mind and good genius, poetical, delighting in learning and elegance, polite, voluptuous, luxurious in their habits of life, joyous, friendly, pious, prudent, fitted for various arts, intelligent, not misled by error, quick in learning, self-teaching, emulous of worth, followers of virtue, copious and agreeable in speech, serene and sincere in manner, delighting in exercise, honest, judicious, high-minded, and continent in desire as regards women[207]; but, when so conciliated and posited adversely, she will make men oppressive, fit for various arts, evil-tongued, unsteady, malevolent, fraudulent, turbulent, liars, calumniators, faithless, crafty, insidious, practised in evil, uncourteous, debauchers of women, corrupters of youth,[208] fond of personal

adornment, dissolute, infamous, notoriously offensive and publicly complained of, yet striving after all things.

Mercury, alone, having dominion of the mind, and being in a glorious position, renders it prudent, clever, sensible, capable of great learning, inventive, expert, logical, studious of nature, speculative, of good genius, emulous, benevolent, skilful in argument, accurate in conjecture, adapted to sciences and mysteries, and tractable: but, when placed contrarily, he makes men busy in all things, precipitate, forgetful, impetuous, frivolous, variable, regretful, foolish, inconsiderate, void of truth, careless, inconstant, insatiable, avaricious, unjust; and altogether of slippery intellect, and predisposed to error.

To these influences and their effects, as above detailed, the Moon also contributes: for, should she be in the bends of her southern or northern boundary,[209] she will render the properties of the mind more various, more versatile in art, and more susceptible of change: if she be in her nodes, she will make them more acute, more practical, and more active. Also, when in the ascendant, and during the increase of her illumination, she augments their ingenuity, perspicuity, firmness and expansion; but, when found in her decrease, or in occultation, she renders them more heavy, more obtuse, more variable of purpose, more timid, and more obscure.

The Sun likewise co-operates, when conciliated with the lord of the mental temperament; contributing, if he be in a glorious position, to increase probity, industry, honour, and all laudable qualities; but, if adversely situated, he increases debasement, depravity, obscurity, cruelty, obstinacy, moroseness, and all other evil qualities.

[Pg 114]

CHAPTER XIX

THE DISEASES OF THE MIND

In connection with the foregoing discussion on the properties of the mind, the circumstances relating to eminent mental disorders, such as madness, epilepsy,[210] and others of the like formidable nature, duly claim attention.

Now, with reference to these, it is always essential to consider the planet Mercury and the Moon, and to observe in what mode they may be disposed towards each other, and towards the angles, and also towards the malefics: for, if the Moon and Mercury be unconnected with each other, or with the oriental horizon, and provided such planets as may be adversely and noxiously configurated should be in elevation above them, or overrule them, or be in opposition to them, the mental properties will then consequently become impregnated with various disorders: the characters of which may be clearly known by the qualities of the stars thus controlling the places.[211]

It is true that there are many disorders of a moderate nature, capable of being distinguished by what has been already stated, in the preceding chapter, regarding the mental qualities: for it is by the increase and growth of certain of those qualities, that an injurious excess is produced; and every irregularity of the moral habit, whether by deficiency or superabundance, may be fitly termed a moral disorder, But, at the same time, there are other disorders of so vast and manifold a disproportion, that they quite, as it were, overpower the natural course of the intellect and passions of the mind. And of these greater disorders it is now proposed to treat.

For example, epilepsy generally attaches to all persons born when Mercury and the Moon may be unconnected either with each other, or with the oriental horizon, while Saturn and Mars may be in angles and superintend the scheme; that is to say, provided Saturn be so posited by day, and Mars by night: otherwise, when the converse may happen in these schemes, viz. when Saturn may have dominion by night, but Mars by

day (especially if in Cancer, Virgo or Pisces), the persons born will become insane. And they will become demoniac, and afflicted with moisture of the brain, if the Moon, being in face to the Sun, should be governed by Saturn when operating her conjunction, but by Mars when effecting her opposition; and particularly when it may happen in Sagittarius and in Pisces.[Pg 115]

If the malefics, only, should have ruled the scheme, in the manner described, the said disorders of the mind will become irremediable, although at the same time not eminent, but doubtful, and not openly displayed; but, should the benefics, Jupiter and Venus, be conciliated, and be posited in eastern parts and in angles, while the malefics may be in western parts, the disorders, although highly conspicuous, will then be susceptible to cure. For instance, under Jupiter's influence, they will be healed by means of medical or surgical aid, and by diet and medicine; under Venus, by the guidance of oracles and by divine interposition.

Should the benefics, however, be occidental, and the malefics be found in eastern parts and in angles, the disorders will then become not only incurable, but most conspicuous: the epileptic persons will then be subjected to constant fits, and to danger of death; the insane will become outrageous and unmanageable, breaking away from their families, raving and wandering in nakedness: the demoniacs and those afflicted with moisture of the brain will become furious, uttering mysterious sayings, and wounding themselves.

The several places of position in the scheme also afford co-operation: for instance, those of the Sun and Mars contribute to insanity; those of Jupiter and Mercury, to epilepsy; those of Venus, to the fury of enthusiasm; and those of Saturn and the Moon, to demoniac affections and moisture of the brain.

It is by such configurations, as those just described, that any morbid deviation, occurring in the active or reasoning faculties of the mind, is produced; but a deviation of the passive, or merely sensitive faculties, is discernible chiefly in the excess and

deficiency (as the case may be) of the masculine and feminine genders; that is to say, in the superabundance, or deficiency, of the power of either gender, to produce a conformation agreeable to its own proper nature: and a knowledge of this latter deviation is to be acquired by means of the following rules.

When the Sun, instead of Mercury, may be with the Moon, and if Mars, together with Venus, be then in familiarity with them, in that case, provided the luminaries only be found in masculine signs, men will excel in their nature, or, in other words, will possess in full plenitude the properties becoming their sex; while the properties of women, who are thus constituted more masculinely and more actively, will deviate from the usual limits of nature. But, if both Mars and Venus, or if only one of them, be likewise masculinely situated, men will be freely and promptly inclined to natural intercourse and connexion; and women will be, in like manner, licentious and intemperate in intercourse beyond nature. Their desires will be practised in privacy, and not openly, should only Venus be situated masculinely; but shamelessly and publicly, if Mars also masculinely placed, together with Venus.

But, if the luminaries only be in feminine signs, women will then [Pg 116]possess their natural functions in greater plenitude, and men will deviate from the limits of nature towards effeminacy and wantonness. And, if Venus be femininely posited, women will be lustful and licentious, and men wanton and soft; seeking connexion contrary to nature; yet in privacy and not openly: but, if Mars be posited femininely, they will then put their desires in practice shamelessly and publicly.

The oriental and diurnal positions of Mars and Venus also contribute to more masculine and more reputable qualities; and their occidental and vespertine[212] positions to qualities more feminine, and more sordid.

Lastly, if Saturn be in familiarity with them, he will likewise co-operate, by tending to produce greater impurity and obscenity, and greater evil altogether; but Jupiter, if in

familiarity, tends to greater decency and modesty, and altogether to better conduct; and Mercury to greater mobility, diversity, activity, and notoriety of the passions.

END OF THE THIRD BOOK

[Pg 117]

BOOK THE FOURTH

CHAPTER I

PROEM

All those circumstances have now been set forth, which occur previously to the birth, as well as at the actual birth, and after it, and which it seemed necessary to mention, as conducing to a knowledge of the general quality of the contemperament produced. And of the other points, now remaining, by which extrinsic events[213] are contemplated, those regarding the several fortunes of wealth and of rank claim to be taken first into consideration. Each of these fortunes has a distinct relationship; for instance, that of wealth relates to the body, and that of rank to the mind.

CHAPTER II

THE FORTUNE OF WEALTH

The circumstances regulating the fortune of wealth are to be judged of from that part alone, which is expressly denominated the Part of Fortune; the position of which is, in all cases, whether arising in the day or in the night, always as far removed from the ascendant as the Sun is distant from the Moon.[214]

When the Part of Fortune has been determined, it must be ascertained to what planets the dominion of it belongs; and their power and connexion, as also the power and connexion of others configurated with them, or in elevation above them, whether of the same or of an adverse condition, are then to be observed: for, if the planets which assume dominion of the Part of Fortune be in full force, they will create much wealth, and especially should the luminaries also give them suitable testimony in addition.

In this manner, Saturn will effect the acquirement of wealth by means of buildings, agriculture, or navigation; Jupiter, by holding some government, or office of trust, or by the priesthood; Mars, by the army [Pg 118]and military command; Venus by means of friends, by the dowry of wives, or by other gifts proceeding from women[215]; and Mercury by the sciences and by trade.

Should Saturn, however, when thus in influence over the fortune of wealth, be also configurated with Jupiter, he particularly provides wealth through inheritance; especially, if the configuration should exist in the superior angles, Jupiter being also in a bicorporeal sign and receiving the application of the Moon; for, in such a case, the native will also be adopted by persons unallied to him, and will become heir to their property.

And, further, if other stars, of the same condition as those which rule the Part of Fortune, should likewise exhibit testimonies of dominion, the wealth will be permanent: but, on the other hand, if stars of an adverse condition should either be in elevation above the ruling places, or ascend in succession to them, the wealth will not continue. The general period of its duration is, however, to be calculated by means of the

declination of the stars, which operate the loss, in respect of the angles and succedent houses.[216]

CHAPTER III

THE FORTUNE OF RANK

The disposition of the luminaries and the respective familiarities, exercised by the stars attending them, are to be considered as indicative of the degree of rank or dignity.[217]

For example, should the two luminaries be found in masculine signs and in angles, or even if only one of them be in an angle,[218] they being at the same time specially attended by a doryphory[219] composed of all the five planets; the Sun by such as are oriental, but the Moon by occidental, the persons then about to be born will [Pg 119]consequently become kings or princes. And, if the attendant stars themselves should also be in angles, or configurated with the angle above the earth,[220] the said persons will become great, powerful, and mighty in the world: and even yet more abundantly so, provided the configurations, made by the attendant stars with the angles above the earth, be dexter. But, when both luminaries may not be found in masculine signs as aforesaid, but the Sun only in a masculine and the Moon in a feminine sign, and only one of them posited in an angle, the other concomitant circumstances still existing in the mode above described, the persons about to be born will then become merely chieftains, invested with the sovereignty of life and death.

And if the attendant stars, while the luminaries may be situated in the manner last-mentioned, should be neither actually in angles, nor bear any testimony to the angles, the persons then born, although they will still enjoy eminence, will attain only some

limited dignity or distinction; such as that of a delegated governor, or commander of an army, or dignitary of the priesthood; and they will not be invested with sovereignty.

If, however, neither of the luminaries be in an angle, and it happen that most of the attendant stars be either themselves in angles, or configurated with the angles, the persons then born will not attain to any very eminent rank; yet they will take a leading part in ordinary civil and municipal affairs: but, should the attendant stars have no configuration with the angles, they will then remain altogether undistinguished and without advancement; and provided, further, that neither of the luminaries be found situated in a masculine sign, nor in an angle, nor be attended by any benefics, they will be born to complete obscurity and adversity.

The general appearance of exaltation or debasement of rank is to be contemplated as before stated, but there are many gradations intermediate to those already specified, and requiring observation of the particular interchanges and variations, incidental to the luminaries themselves and their doryphory, and also to the dominion of [Pg 120]the planets which compose their doryphory. For instance, should the benefics, or stars of the same condition, exercise the chief dominion, the dignities to be acquired will be not only important, but also more securely established; and, on the other hand, if the chief dominion be claimed by the malefics, or by stars of an adverse condition, the dignities will be more subordinate, and more dangerous and evanescent.

The species of dignity may be inferred by observing the peculiar qualities of the attendant stars. And, if Saturn have chief dominion of the doryphory, the power and authority derived therefrom will lead to wealth and profit: authority proceeding from Jupiter and Venus will be pleasurable, and attended by presents and honours: that proceeding from Mars will consist in commanding armies, in obtaining victories, and in overawing the vanquished: and that proceeding from Mercury will be intellectual, superintending education and study, and directing the management of business.

CHAPTER IV

THE QUALITY OF EMPLOYMENT

The dominion of the employment, or profession, is claimed in two quarters; viz. by the Sun, and by the sign on the mid-heaven.

It is, therefore, necessary to observe whether any planet may be making its oriental appearance nearest to the Sun,[221] and whether any be posited in the mid-heaven; especially, when also receiving the application of the Moon. And if one and the same planet possess both these qualifications, that is to say, make its nearest appearance to the Sun, and be also in the mid-heaven, that one alone must be elected to determine the present inquiry: and, likewise, though the planet should not be thus doubly qualified, but only singly, in whichever respect, even then that planet alone must still be elected provided itself alone should possess such single qualification. If, however, there should be one planet presenting its nearest appearance, and another in the mid-heaven conciliating the Moon, both must then be noticed; and whichever of two may have greater sway, and possess greater rights of dominion, that one must be preferred. But where not any planet may be found so situated, neither making its appearance as above described, nor being in the mid-heaven, then that one, possessing the dominion of the mid-heaven,[222] is to be considered as lord of the[Pg 121] employment: it is, however, only some occasional occupation which can be thus denoted; because persons, born under such a configuration, most commonly remain at leisure and unemployed.

What has now been said, relates to the election of the lord of the employment or profession; but the species of the employment will be distinguished by means of the respective properties of the three planets, Mars, Venus, and Mercury, and of the signs in which they may be posited.

Mercury, for instance, produces writers, superintendents of business, accountants, teachers in the sciences, merchants and bankers: also, soothsayers, astrologers, and attendants on sacrifices, and, in short, all who live by the exercise of literature, and by furnishing explanation or interpretation; as well as by stipend and salary, or allowance. If Saturn bear testimony jointly with Mercury, persons then born will become managers of the affairs of others, or interpreters of dreams, or will be engaged in temples for the purpose of divination, and for the sake of their fanaticism. But, if Jupiter join testimony, they will be painters, orators, or pleaders in argument, and occupied with eminent personages.

Should Venus have dominion of the employment, she will cause persons to be engaged in the various perfumes of flowers, in unguents and wines, and also in colours, dyes, and in spices: thus she will produce vendors of unguents, garland-makers,[223] wine-merchants, dealers in medical drugs, weavers, dealers in spices, painters, dyers, and vendors of apparel. If Saturn add his testimony to hers, he will cause persons to be employed in matters belonging to amusement and decoration; and will also produce jugglers, sorcerers and charlatans, and all such as practise similarly. But, if Jupiter join testimony with Venus, persons will become prize-wrestlers, and garland-wearers,[224] and will be advanced in honour through female interest.

Mars, ruling the employment, and being configurated with the Sun, will produce persons who operate by means of fire; for instance, cooks, as [Pg 122]well as those who work in copper, brass, and other metals, by melting, burning, and casting: if Mars be separated from the Sun, he will make shipwrights, smiths, agriculturists, stonemasons, carpenters, and subordinate labourers. If Saturn bear testimony, in addition to Mars, persons will become mariners, workers in wells, vaults or mines, painters, keepers of beasts or cattle, cooks or butchers, and attendants on baths or on exhibitions. And, if Jupiter join testimony, they will be soldiers, or mechanics, collectors of revenue, inn-keepers, toll-gatherers, or attendants on sacrifices.

Further, should it happen that two arbiters of employment may be found together, and provided they should be Mercury and Venus, they will then produce musicians, melodists, and persons engaged in music, poetry, and songs: they will also produce (especially if changed in their places)[225], mimics, actors, dealers in slaves, makers of musical instruments, choristers and musical performers, dancers, weavers, modellers in wax, and painters. And if Saturn join testimony with Mercury and Venus, the preparation and sale of female ornaments will be added to the aforesaid occupations. But, if Jupiter give testimony, the persons will become administrators of justice, guardians of public affairs, instructors of youth, and magistrates of the people.

Should Mercury and Mars together be lords of the employment, persons will become statuaries, armour-makers, sculptors,[226] modellers of animals, wrestlers, surgeons, spies or informers, adulterers, busy in crime, and forgers. And, if Saturn also bear testimony in addition to Mercury and Mars, he will produce assassins, highwaymen, thieves, robbers lurking in ambush, marauders on cattle, and swindlers. But, if Jupiter afford testimony, he will engage persons in honourable warfare, and in industry; making them cautious and diligent in business, curious in foreign matters, and deriving profit from their pursuits.

When Venus and Mars exercise the dominion together, persons will become dyers, dealers in unguents and perfumes, workers in tin, lead, gold, and silver, mock combatants or dancers in armour, dealers in medical drugs, agriculturists, and physicians, healing by means of medicine. And if Saturn add testimony to Venus and Mars, he will produce persons attendant on animals consecrated to religion; also grave-diggers and undertakers, mourners and musicians at funerals, and fanatics occupied in religious ceremonies, lamentations, and blood. But, if Jupiter add testimony, the persons will become regulators of sacrifices, augurs, holders of sacred offices, governors placed over women, and interpreters; and they will derive support from such occupations.

zaid n. adwan

The properties of the signs, in which the lords of the employment may be posited, are also influential in varying the employment. For example, [Pg 123]the signs of human shape promote all scientific pursuits, and such as are of utility to mankind; the quadrupedal signs contribute to produce employment among metals, in business and trade, in house-building, and in the work of smiths and mechanics: the tropical and equinoctial signs tend to give employment in translation or interpretation, in matters of exchange, in mensuration and agriculture, and in religious duties: the terrestrial and watery signs tend to employment in water, and in connection with water, as well in regard to the nurture of plants, as to ship-building; they likewise contribute to employment in funerals, in embalming and preserving, and also in salt.

Moreover, should the Moon herself actually occupy the place regulating the employment,[227] and, after her conjunction, continue in course with Mercury, being at the same time in Taurus, Capricorn, or Cancer, she will then produce soothsayers, attendants on sacrifices, and diviners by the basin.[228] If she be in Sagittarius or Pisces, she will make necromancers, and evokers of dæmons: if in Virgo or Scorpio, magicians, astrologers, and oracular persons, possessing prescience: and, if in Libra, Aries, or Leo, she will produce fanatics, interpreters of dreams, and makers of false vows and adjurations.

From the foregoing rules, the various forms of employment are to be inferred; and its magnitude or importance will be manifested by the existing power of the ruling planets. For instance, if the said planets be oriental, or in angles, they will give the person eminence and authority in his employment; but, if occidental or cadent, they will render him subordinate. And should the benefics be in elevation, the employment will be important, lucrative, secure, honourable, and agreeable; but, on the other hand, if the malefics be in elevation above the lords of the employment, it will then be mean, disreputable, unprofitable, and insecure: thus, Saturn brings an adverse influence in coldness or tardiness, and in the composition or mixture of colours[229]; and Mars

produces opposition by audacity and publicity in enterprise: [Pg 124]and both planets are alike hostile to proficiency and prosperity.

The general period, at which any increase or diminution of the employment may take place, must, again in this case also, be determined by the disposition of the stars, which operate the effect towards the oriental and occidental angles.

CHAPTER V

MARRIAGE

The consideration of circumstances relating to marriage, or the cohabitation of husband and wife, as sanctioned by law, succeeds to the foregoing details, and must be pursued in the following method.

With regard to men, it is to be observed in what manner the Moon may be disposed; for, in the first place, if she be found in the oriental quadrants, she will cause men either to marry early in life, or, after having over-passed their prime, to marry young women; "but, should she be situated in either of the occidental quadrants, men will then marry either late in life, or to women advanced in age[230]": and if she be found under the Sun's beams, and configurated with Saturn, she then entirely denies marriage. Secondly, should she be in a sign of single form, and in application to only one of the planets, she will cause men to marry only once; but, if she be in a bicorporeal or multiform sign, or in application to several planets, she will cause them to be married several times; and, provided also that the planets, which thus, either by adjacency or by testimony,[231] receive her application, be benefic, men will then obtain good wives; but if, on the contrary, the said planets be malefic, bad. For example, if Saturn receive the Moon's application, the wives whom he will provide will be troublesome and morose; but, if Jupiter receive it, they will be decorous and economical; if Mars, bold and

refractory; if Venus, cheerful, handsome, and agreeable; and, if Mercury, sensible, prudent, and clever. Moreover, should Venus be found connected with Jupiter, Saturn,[232] or Mercury, she will render wives provident, and attached to their husbands and children; but, if she be found connected with Mars, they will be irascible, unsteady, and indiscreet. Thus far in reference to the marriage of men.

But, in the case of women, the Sun must be observed, instead of the Moon: and, should he be posited in the oriental quadrants, women will [Pg 125]be married either in their own youth, or to men younger than themselves; but, if he be in the occidental quadrants, they will either be married late in life, or to men who have passed their prime, and are advanced in years. And should the Sun be in a sign of single form, or configurated with only one oriental planet, he will cause them to enter into matrimony only once; but, if in a bicorporeal or multiform sign, or configurated with several oriental planets, he will then cause them to be often married. And Saturn, being configurated with the Sun, will provide husbands steadfast, advantageous, and industrious; Jupiter, such as are honourable and noble-minded; Mars, severe husbands void of affection and intractable; Venus, amiable and handsome husbands; and Mercury, such as are provident and expert in business. But, if Venus be found connected with Saturn, she will indicate dull and timid husbands; "if with Jupiter, the husbands will be good, just, and modest[233];" if with Mars, hasty, lustful, and adulterous; and if with Mercury, they will be extravagantly desirous of young persons.[234]

In regard to the Sun, those quadrants which precede the ascending and descending points of the zodiac, and, in respect of the Moon, those which are measured from her conjunction and opposition[235] to her intermediate quarters, are called oriental quadrants: the occidental quadrants are, of course, those lying opposite to the oriental.

Whenever both nativities, viz. that of the husband and that of the wife, may exhibit the luminaries configurated together in concord, that is to say, either in trine or in sextile to each other, the cohabitation will most usually be lasting; especially if the said concord

exist by means of interchange[236]; but its duration will be also much more securely established, provided the Moon in the husband's nativity should correspond or agree with the Sun in the wife's nativity.[237] If, however, the relative positions of the luminaries be in signs inconjunct, or in opposition, or in quartile, the cohabitation will be speedily dissolved upon slight causes, and the total separation of the parties will ensue.

And should the configuration of the luminaries, when made in concord, be aspected by the benefics, the cohabitation will continue in respectability, comfort, and advantage; but, on the other hand, it will abound in strife, contention, and misfortune, if the malefics be in aspect to the said configuration.

In like manner, even though the luminaries may not be favourably [Pg 126]configurated in concord, should the benefics still offer testimony to them, the cohabitation will then not be entirely broken off, nor totally destroyed for ever, but will be again renewed, and re-established as before. But if, on the contrary, the malefics bear testimony to such discordant disposition of the luminaries, a dissolution of the cohabitation will take place, accompanied by scorn and injury. Should Mercury alone be conjoined with the malefics, it will be effected by means of some public inculpation; and if Venus also be found with them, it will be on the ground of adultery, or sorcery, or some similar offence.

There are, however, other varieties in the married state, which are to be contemplated by means of Venus, Mars, and Saturn. And should these planets act in familiarity with the luminaries, the cohabitation will be appropriate and domestic, and authorised by law; because Venus holds a certain affinity both to Mars and Saturn: her affinity to Mars, for instance, consists in each having exaltation in a sign belonging to the other's triplicity,[238] and it operates in the cases of youthful and vigorous persons: while her affinity to Saturn arises from their respective houses being in the signs, again

also, belonging to each other's triplicity,[239] and relates to persons of more advanced age.

Hence, if Venus be in concurrence with Mars, she will produce entire love and affection in the cohabiting parties; and if Mercury also coincide with the said planets, such affection will become publicly notorious. Should Venus be found in a sign mutually common and familiar, such as Capricorn, or Pisces,[240] she will effect marriages between brothers and sisters and kindred by blood: and, provided she be also in the presence of the Moon, when the native may be male, she will cause him to connect himself with two sisters, or other near relatives; but, if the native be a female, a similar contract on her part, with two brothers or near relatives, will be indicated, when Venus may be also with Jupiter.[241]

Again, if Venus be with Saturn, the cohabitation will be established entirely in happiness and constancy; and if Mercury be present with them, it will be profitable; but, should Mars be present, it will be unsettled, calamitous, and afflicted by jealousy. And if Mars be configurated on equal terms with Venus, Saturn, and Mercury, he will effect marriage between persons of equal age; but, on the other hand, should he be more oriental, marriage will take place with a younger man or woman; and, if more occidental, with an older person. Should Venus [Pg 127]and Saturn be found in signs common to each other, that is to say, in Capricorn and Libra,[242] marriage will be contracted between persons kindred by blood: and, when the said position may happen in the ascendant, or in the mid-heaven, provided the Moon also should present herself there, men will become connected with their mothers, or maternal aunts, or with their mothers-in-law; and women with their own sons, or the sons of their brothers, or with their daughters' husbands. But if, instead of the Moon, the Sun should be in concurrence with the said position, and especially should it happen that the planets in question may be occidental, men will then connect themselves with their daughters, or the wives of

their sons; and women with their fathers, or paternal uncles, or the husbands of their daughters.

When the aforesaid configurations,[243] although not existing in signs of affinity to each other,[244] should be found in feminine places, they will render the parties obscene, lustful and shameless; for instance, when found in the anterior and hinder parts of Aries, and near the Hyades of Taurus, about the urn of Aquarius, in the hinder parts of Leo, and in the face of Capricorn. And should the last-named planets, Venus and Saturn, be posited in angles, they will then, if posited in the first two angles, the eastern and southern, produce a total exposure of the passions, and cause them to be publicly canvassed; but, if in the last two angles, the western and northern, they will produce eunuchs, or persons unprolific, and not possessing the proper channels of nature.

The passions, liable to operate in males, are to be considered by observation of Mars: for should he be separated from Venus and Saturn, but yet, at the same time, be supported by the testimony of Jupiter, he will make men pure and decorous in sexual intercourse, and incline them to natural usages only: and, if he attach himself to Saturn only, he will render them cold in blood and dull in appetite; if, however, when Saturn and Mars may be thus connected together, Venus and Jupiter should also be configurated with them, men will then become easily excited and eager in desire, although they will still be continent, and restrain themselves in order to avoid reproach. But should Saturn be absent, and Mars be with Venus alone, or even although Jupiter also be with her, men will become highly licentious, and attempt to gratify their desires in every mode.[245] And further, if Venus be found more occidental, men will connect [Pg 128]themselves with low women, female servants, and aliens or vagabonds; but, should Mars be found occidental, with women of rank, and gentlewomen; or with women living with their husbands, or under the protection of men. Thus far with regard to males.

In the case of females, Venus requires attention: for, if she be configurated with Jupiter, or with Mercury, she will cause women to be temperate and pure in sexual intercourse; still, however, when she may be thus connected with Mercury, if Saturn be not present also, she will cause them to be easily excited to desire; although they will control their desires, and avoid reproach. But, should Venus be conjoined or configurated with Mars alone, she will render women licentious and lustful; and if, to both these planets, when thus conjoined or configurated, Jupiter also present himself, Mars being at the same time under the rays of the Sun, women will then mingle in intercourse with servants, and persons meaner than themselves, or with aliens, or vagabonds: but, should it happen that Venus may be under the rays of the Sun, they will then connect themselves with their superiors or masters. And, further, should the planets be in feminine places, or configurated femininely, they will be content with their passive faculties only.[246]

Saturn, in being conciliated with such positions as those now described, tends to produce greater obscenity; Jupiter, greater decency; and Mercury, greater publicity, and greater fickleness, or instability.

CHAPTER VI

CHILDREN

The next point to be investigated is that concerning children: and, to accomplish this, observation must be made of the planets posited in, or configurated with the place on the zenith,[247] or its succedent house, which latter is called the place of the good dæmon. And should it happen that not any planets may be present in the said places, nor configurated with them, it will then be necessary to take into consideration such as may be in opposition thereto.

Now the Moon, Jupiter, and Venus are esteemed as givers of offspring; but the Sun, Mars, and Saturn are considered as denying children altogether, or as allowing but few:

while Mercury, being in quality common to both parties, lends co-operation to that with which he may be configurated, and gives offspring, when oriental, but withholds, when occidental.[Pg 129]

To speak briefly, if the planets, which grant progeny, be so posited as described,[248] and placed singly, the gift of progeny will be single only[249]; but should they be in bicorporeal or in feminine signs, they will grant double offsprings[250]: so likewise if they should be in prolific or seminal signs, such as Pisces, Cancer, and Scorpio, they will grant twins, or even more. And provided they should also be masculinely constituted, as well by configuration with the Sun, as by being in masculine signs, they will grant male children; but otherwise, if femininely constituted, female.

But, although the said planets, even if beneath the malefics in elevation, or, even if found in barren places, or in signs such as those of Leo and Virgo, will still grant children; yet such children, thus indicated, will neither be healthy, nor continue in life. Should it happen, however, that the Sun and the malefics may be in entire possession of the places above mentioned, viz. that on the zenith, or the succedent house allotted to the good dæmon; and provided they be, at the same time, in masculine or barren signs, and the benefics be not in elevation above them, a total privation of offspring is thereby indicated; but, should they be in feminine or prolific signs, or supported by the testimony of the benefics, children will then be granted; yet they will be liable to disease, and short-lived.

If, however, planets of each condition should be configurated with, and have prerogative in prolific signs, there will then ensue a loss of either all the children, or only few, or else the major part of them; in the same proportion as that in which the planets, bearing testimony to either condition, may preponderate on one side rather than the other; by excelling in number, or in influence, in consequence of being posited more orientally, more genuinely in angles, higher in elevation, or successively ascending.

When the lords of the aforesaid signs[251] may be such as are givers of offspring, and be either oriental, or in places proper to themselves, the children thus granted will become eminent and illustrious: but, if occidental, or in places not proper to themselves, the children will then become undistinguished and abject. Should the said lords also be in concord with the part of fortune, and with the ascendant, they will render the children amiable, and cause them to be beloved by their parents, and to inherit their parents' substance: but, if found inconjunct, and not in concord with the said parts, the children will then become odious and mischievous to their parents, and will forfeit the inheritance of their substance.[Pg 130]

Further, should the planets which grant progeny be appropriately configurated with each other, they will promote brotherly love, and mutual regard and affection among the children; but, if inconjunct, or in opposition, they will excite in them mutual hatred, deceit, and treachery.

The general investigation regarding children is to be conducted in the foregoing method: but, in order to enquire into particular circumstances consequent on the above, it will be necessary to assume, as an ascendant, the position of each planet which gives offspring, and to observe the separate schemes; drawing inferences therefrom as in the case of a nativity.

CHAPTER VII

FRIENDS AND ENEMIES

With respect to friendship and enmity, it may be observed that great and lasting familiarities, or disagreements, are respectively called sympathies and enmities; while the smaller, such as arise occasionally, and subsist for a short time only, are

zaid n. adwan

denominated casual intimacies and strifes: the whole are to be contemplated according to the following rules.

Indications of great and lasting friendships, or enmities, may be perceived by observation of the ruling places, exhibited in the respective nativities of both the persons, between whom the friendship or enmity may subsist. It is consequently essential to observe the places of the Sun, the Moon, the ascendant, and the part of fortune; for, should all these in both nativities be in the same signs, or should either all or most of them be counterchanged in position in each nativity, and especially should the two ascendants be within the distance of seventeen degrees from each other,[252] they will create fixed and indissoluble friendship. On the other hand, should they be in signs inconjunct, or in opposition, they will produce great and lasting enmity. If, however, they be not constituted in either of the modes above mentioned, but merely configurated in signs,[253] they will then produce minor friendship; provided such configuration exist by trine or sextile; but, if by quartile, they will excite minor enmity, so as to take effect at certain particular times, in which the friendship remains, as it were, inactive and subdued, while the malefics transit the configuration: and, in a similar manner, enmity also will be softened and abated, when the benefics may enter upon the configuration.[254]

[Pg 131]The friendship and enmity, which men bear towards each other, may be classed under three general heads. One kind is suggested by spontaneous wilfulness; another, by the idea of profit; and another, by pain and pleasure mutually excited.

And, therefore, should either all or most of the aforesaid places be in familiarity with each other, friendship of all the three kinds will be established: so, also, should the places be entirely without familiarity, similar enmity will be established. If, however, familiarity, or absence of familiarity (as the case may be), exist only as regards the places of the luminaries, friendship or enmity will then be established by spontaneous will; and friendship thus produced is the best and most secure; while, on the other hand, enmity so arising is, in like manner, the worst and most dangerous. The friendship, or

enmity, consequent on the familiarity or non-familiarity of the respective parts of Fortune, will be established on the idea of profit; and that, consequent on a similar disposition of the respective ascendants, will arise from pain or pleasure mutually excited between the parties.

It will, however, be necessary to pay still further attention to the places in question, in order to observe whether any and what planets may be in elevation above them, or in aspect to them; because, among all the said places, that particular one, to which any planet in elevation, or in succession, may be adjacent, whether in the same sign, or in the next, will possess the more powerful influence over friendship or enmity: and whichever place may have its aspecting planets more powerfully benefic, will operate in a greater degree[255] to advantage in friendship, and to the relaxation of enmity. The foregoing instructions are applicable to such friendships or enmities as are great and lasting.

But, in the case of others, which subsist only occasionally, and which have been defined as casual intimacies and strifes, it is essential to make observation of the motions of the planets, as exhibited by each nativity; that is to say, the times are to be calculated, on the completion of which the motions of the planets of one nativity will cause them to enter on certain places of the other nativity; for it is at such periods that certain particular friendships and enmities occur, continuing for a short time, until the said ingress of the planets shall have passed over.

For instance, Saturn and Jupiter, when making ingress upon each other's places, produce friendship by certain agreements, or engagements, relating either to agriculture or to inheritance: Saturn and Mars create contention and treachery spontaneously entertained: Saturn and Venus, friendship between kindred; liable, however, soon to grow cool: Saturn and Mercury, friendship on account of business, or profit, or some secret art or mystery.

Jupiter and Mars create friendship in the direction of affairs, and by means of dignities; Jupiter and Venus also create friendship by means of [Pg 132]female persons, or attendants on religion, or on oracles: Jupiter and Mercury, friendship by means of eloquence and science, and philosophical inclinations.

Mars and Venus cause friendship in the course of amours, adultery, and fornication: Mars and Mercury excite hatred and strife by offences committed in business and trade, or by sorcery.

And Venus and Mercury produce communion by means of the arts and sciences, by a mutual interest in literature, or by female persons.

It is in this manner that the planets operate in producing friendship or enmity. And their comparative intensity or relaxation of vigour is to be distinguished by the situation of the places, which they occupy, with regard to the four principal and ruling places[256]: for, should they be posited in angles, at the places of the respective parts of Fortune, or at those of the luminaries, they will render the casual intimacies or strifes more eminent and remarkable; but, if they be remote from these places, their effects will not be highly conspicuous. The comparative degree of injury or advantage, liable to be received, is to be discerned by means of the good or evil properties of such planets as may be thus in aspect to the aforesaid places.

With respect to servants,[257] the sign of the evil dæmon[258] is considered as the place to which the disposition ruling over them must be referred; and it is to be observed what planets are in aspect to that place, both at the actual time of nativity, and at that of any ingresses made upon it, or oppositions to it; and also, especially, whether the lords of the said sign may be configurated in familiarity with the ruling places of the nativity, or not in familiarity.

CHAPTER VIII

TRAVELLING

The circumstances indicative of travel are to be considered by means of the situation held by both the luminaries, in respect to the angles, and especially, by means of that held by the Moon. For, should she be descending, or cadent from the angles, she will cause journeys and changes of residence: Mars, also, if descending, or cadent from the zenith, will sometimes do the same, provided he may occupy a situation in quartile, or in opposition to the luminaries. And, if the part of Fortune, also, should happen to be placed in signs which produce travelling, the course and practice of the whole life will be engaged [Pg 133]in foreign lands. And further, provided the benefics superintend the aforesaid places, or ascend in succession to them, the engagements abroad will be honourable and lucrative, and the return home speedy and unobstructed: but if, on the contrary, the malefics superintend or ascend in succession to those places, the journey outward will then lead to peril and misfortune, and the return will be replete with difficulty. But it is, at the same time, necessary in all cases to consider the contemperament also, and to observe such of the existing configurations as are more predominant.

It most usually happens, that, if the luminaries be posited in the cadent houses of the oriental quadrants, the travel will take place in the eastern or southern quarters of the world; and that, if placed in western situations, or in an occidental quadrant, travel will be then prosecuted in the northern or western parts. And, should the signs, which operate travel, be themselves single in form, or should the planets, having dominion of them, be singly posited, the journeys will then take place after long intervals, and occasionally only: but, if the said signs be bicorporeal, or double in form or figure, travel will be constantly repeated and continued.

Thus, when Jupiter and Venus may be in dominion over the luminaries, and over the places producing travel, they will render the journeys agreeable, as well as free from

danger: for the traveller will be joyfully forwarded on his way by the magistrates of the country, and by the concurrent assistance of friendly persons; the state of the atmosphere will also be favourable, and he will meet with abundance of accommodation. And, provided Mercury also be present with the planets above specified, utility, profit, presents and honours will likewise be derived from the journey.

Saturn and Mars, if controlling the luminaries, and, especially, if placed distant from each other,[259] will produce great dangers, and at the same time render the journey fruitless and unavailing. Should they be in watery signs, the dangers will arise by shipwreck, or among deserts and wilderness[260]; if in fixed signs, by precipices, and adverse blasts of wind; in tropical and equinoctial signs, by want of food and other necessaries, and by some unwholesome state of the atmosphere; in signs of human form, by robbery, treachery, and various depredations; and, if in terrestrial signs, by the attack of wild beasts, or from earthquakes. And, should Mercury also lend concurrence, the traveller will incur further danger from accusations made against him, as well as from reptiles and venomous stings or bites.

The question, whether the events will be advantageous or injurious in quality, must, however, be further considered by observation (made in [Pg 134]the forms already detailed), of the peculiar properties of the places, in which the lords of employment, of wealth, of the body, or of rank, may be posited. And the periods, at which travelling will take place, are to be considered by the occasional ingress of the five planets.[261]

CHAPTER IX

THE KIND OF DEATH

It now remains to treat of the kind and species of death. It is, however, first to be determined, by the rules already delivered regarding the duration of life,[262] whether

death will ensue from an oriental or occidental position of the predominating influence. And, if death ensue from some oriental position, or meeting of rays, the place of such meeting must be observed, and by means of that place the kind of death is to be distinguished; if from the descension, or setting, of the significator, or prorogator, the place of descension[263] must be considered: because death is to be expected conformable in character to the influences, whatever they may be, which preside over the said places; or, if not any influences should directly preside, it will then be conformable to the influences, of whatever kind, which may be brought first in succession to the places in question: the configuration of the stars, the property of the aforesaid anæretic places, and the nature of the signs and of the terms,[264] are, also, all of them co-operative.

Thus, for example, if the dominion of death be vested in Saturn, he will produce death by means of lingering diseases; cough, rheumatism, flux, ague, disorder of the spleen, dropsy, colic, and complaints in the womb; and, in short, by all such diseases as proceed from the superabundance of cold.

Jupiter effects death by quinsey, inflammation of the lungs, apoplexy, spasm, pains in the head, morbid performance of the heart, and by all diseases arising from the superabundance of air, and from immoderate and impure respiration.

Mars causes death by constant fevers, semitertians, sudden and spontaneous wounds, diseases of the kidneys, expectoration of blood, and hæmorrhages of various kinds; by miscarriage, or abortion, and by childbirth, by erysipelas, and, in short, by such diseases as proceed from abundant and immediate heat.

Venus produces death by disorders of the stomach, and of the liver, by [Pg 135]scurvy and dysentry: also by consumption or wasting away,[265] and by fistula and poison, and by all diseases incident on the superabundance or poverty of moisture, and its corruption.

Lastly, Mercury causes death to proceed from fury, madness, melancholy, epilepsy, falling fits, coughs, and obstructions, and by such diseases as arise from superabundant or disproportionate dryness.

When the lords of death may fully possess their own peculiar and natural properties, and when neither of the malefics may be in elevation above them, death will ensue in the modes above detailed, and in the ordinary course of nature. But a violent and remarkable death will occur when both the malefics, either in conjunction, or in quartile or opposition to each other, may be lords of the anæretic places; or if both, or only one of the two, should attack either both the luminaries, or even only the Sun or the Moon. In such a case, the evil character of the death will proceed from the concurrence of the malefic influence, and its magnitude or remarkable nature from the additional testimony of the luminaries: its quality, also, will be known by means of the rest of the planets and stars in configuration, and by the signs which contain the malefic influence.[266]

Hence, if it happen that Saturn be in fixed signs, and in quartile or opposition to the Sun, and contrary in condition, he will produce death by suffocation, occasioned either by multitudes of people, or by hanging or strangulation: so, likewise, should he be occidental, and the Moon be succedent to him, he will operate the same effects. If he be posited in places or signs of bestial form, the native will be destroyed by wild beasts: and, if Jupiter also offer testimony, being at the same time badly afflicted, the death will then occur in public, and by day; for example, by being exposed to combats with wild beasts. If Saturn be posited in opposition to either of the luminaries in the [Pg 136]ascendant,[267] he will cause death in prison: if he be configurated with Mercury, and especially if near the constellation of the Serpent in the sphere, and in terrestrial signs of the zodiac, he will produce death by venomous wounds or bites, and by reptiles and wild beasts. And, should Venus also attach herself to Saturn and Mercury thus combined, death will then ensue by poison or female treachery. If Saturn be in Virgo or Pisces, or watery signs, and configurated with the Moon, he will operate death by means

of water, by drowning and suffocation; and, if found near Argo, by shipwreck. Should he be in tropical or quadrupedal signs, and the Sun be either in conjunction with him, or in opposition; or if, instead of the Sun, Mars should so present himself, death will be caused by the fall of houses or buildings; and, if posited in the mid-heaven, death will happen by falls from heights or precipices. These are the various effects of Saturn, when configurated as described.

Mars, if in signs of human form, and posited in quartile or in opposition to the Sun or Moon, and contrary in condition, will operate death by slaughter, either in civil or foreign war, or by suicide: if Venus add her testimony, death will be inflicted by women, or by assassins in the employment of women: and, should Mercury also be configurated with them, death will happen from robbers, thieves, or highwaymen. If Mars be in mutilated or imperfect signs, or near the Gorgon[268] of Perseus, he will produce death by decapitation, or by mutilation of limb. If found in Scorpio or Taurus, he will cause death by surgical amputation, burning or searing, or also by spasms or convulsions. Should he be found in the mid-heaven, either above or below the earth, death will be inflicted by crucifixion or impalement, and especially if he be in the vicinity of Cepheus or Andromeda. If descending, or in opposition to the ascendant,[269] he will produce death by fire: and, if in quadrupedal signs, by falls and fractures. Should Jupiter, however, bear testimony to Mars, and be at the same time afflicted, death will ensue from the wrath of princes and kings, and from judicial condemnation.

If it happen that the malefics be in concurrence with each other in the first instance, and afterwards in mutual opposition, in any of the aforesaid situations, the evil character of the death will be yet further augmented; but its species or quality, and its dominion, will depend upon that one which may be in occupation of the anæretic place. And, if both the malefics claim prerogative in the anæretic places, the bodies of persons who thus die will be cast abroad without interment, and will be devoured by beasts and birds: these circumstances will especially ensue, when the malefics may be found in signs

similar in form to beasts and birds; and provided not any one of the benefics should offer testimony to the place below the earth,[270] nor to the anæretic places.[Pg 137]

Lastly, death will occur in foreign lands, when it may happen that the planets controlling the anæretic places may be posited in cadent houses; especially if the Moon be present in the said places also, or if she be found in quartile or in opposition.[271]

CHAPTER X

THE PERIODICAL DIVISIONS OF TIME

In addition to the foregoing brief observations, applicable to the various forms of death, further attention is demanded with respect to the division of time, which requires to be contemplated in its natural order and succession.

Now as, in all genethlialogical cases, a certain common and general arrangement, affecting the region or country and the race or generation, is pre-supposed to be in operation, to which arrangement particular inferences, relating to the form of the body, the properties of the mind, and national habits and variations, must each be subservient; and as, in these respects, certain causes more general and predominating are pre-supposed in existence before particular causes, due care must consequently be taken, in order to make an inference consistent with the course of nature, to observe always the original and predominating cause, and never to lose sight of it; lest some similarity in nativities (if any such should exist) might induce an assertion when the original predominating cause proceeding from the region itself has been overlooked, that the native of Æthiopia will be born of white complexion, and with long and straight hair; or, on the other hand, that the native of Germany or of Gaul will be black in [Pg 138]complexion, and have curled hair; or, that the said nations are polished in manners, and cultivate learning, but that the people of Greece are barbarous and illiterate: and so,

in short, of any other countries; without duly considering the national differences and variations in their several courses of life. So also, with regard to the division of time, it is in the same manner essential to consider the different qualities of the several ages of life, and to pre-determine the appropriate fitness of every age to such events as may be expected: in order to avoid the gross error which might arise from a merely vague consideration of the subject, by attributing to infancy some deed or circumstance of too complete a nature and belonging rather to manhood, or by ascribing to extreme old age the procreation of children, or some other action belonging to youth; and to adapt, on the contrary, to each separate age such circumstances as seem, by due observation of the periods, to be suitable and appropriate thereto.

The mode of consideration[272] applicable to human nature is universally one and the same; and it is analogous to the arrangement of the seven planetary orbs.[273] It, therefore, duly commences with the first age of human life, and the first sphere next above the earth, that of the Moon; and it terminates with the final age of man, and the last of the planetary spheres, which is that of Saturn; and, in fact, it accordingly happens that the appropriate qualities of each sphere take effect in a corresponding age of life, each age being subjected to one particular sphere. These observations are necessary, because the general divisions of time must be considered by means of the spheres, as a primary arrangement; although minor distinctions are to be made by means of the existing peculiarities found in nativities.

Hence, the first age of infancy, which endures for four years, agreeing in number with the quadrennial period of the Moon, is consequently adapted to her; being in its nature moist and incompact, presenting rapidity of growth, being nourished by moist things, and possessing a highly variable habit. Its mental incompleteness is likewise in accordance with its familiar relation to the Moon, and her operative influence.

The age after this continues for ten years, and accommodates itself to the second sphere, that of Mercury. In this period, the intellectual and reasoning faculties of the

zain.adwan

mind begin to take their character, imbibing the seeds of learning, and developing, as it were, the elements and germs of the genius and abilities, and their peculiar quality. The mind is also roused to discipline and instruction, and to its first exercises.

Venus corresponds with the next and third age, which lasts throughout the following eight years, the number of her own period: from her, the movement of the seminal vessels originates, as well as an unrestrained impetuosity and precipitancy in amours.[Pg 139]

The fourth and adult age next succeeds, and is subject to the fourth sphere, that of the Sun: it endures for nineteen years, according to the Sun's number. Authority of action now commences in the mind, the career of life is entered upon, distinction and glory are desired, and puerile irregularities are relinquished for more orderly conduct, and the pursuit of honour.

Mars, next after the Sun, claims the fifth age, that of manhood, agreeing in duration with his own period, viz. fifteen years. He induces greater austerity of life, together with vexation, care, and trouble.

Jupiter occupies the sixth sphere, and influences the maturer age, during the twelve years corresponding to his own period. He operates the relinquishment of labour, of hazardous employment and tumult, and produces greater gravity, foresight, prudence, and sagacity, favouring the claim to honour, respect, and privilege.

Saturn, moving in the last sphere, regulates the final old age, as agreeing with its chilliness. He obstructs the mental movements, the appetites and enjoyments; rendering them imbecile and dull, in conformity with the dullness of his own motion.

The common properties attributable to the various times of life are subject, in a general manner, to this previous adaptation; but there are particular periods, arising from the respective peculiarities of nativities, which also require determination, and must be ascertained from the ruling prorogations; that is to say, from the whole of them,

and not from any single one only, as in the case of the duration of life. For example, prorogation made from the ascendant is to be applied to events affecting the body, and to travelling, or change of residence; that from the part of Fortune, to incidents affecting the substance or wealth; that from the Moon, to actions of the mind, and to communion[274] and cohabitation; that from the Sun, to dignities and glory; and that from the mid-heaven, to other particular circumstances of life, such as employment, friendship, and the possession of children. So that thus, at one and the same time any single planet, whether benefic or malefic, will not possess the sole dominion; for many conflicting events frequently occur at the same period, and a person may, at one and the same time, lose a kinsman, yet inherit his substance; or be at once ill in health, yet prosperous and advantageously established in regard to fortune; or be struggling with adversity and in want, yet, notwithstanding, be also a father and beget children; or he may experience other similar contrarieties: because individuals are subject to occurrences which may affect either the body, the mind, the rank, or the condition of wealth, and which are not altogether fortunate or unfortunate at the same period. Something of the kind will, however, frequently happen in cases of perfect good fortune or distress, when [Pg 140]meetings of all the benefics or malefics may concur in all or most of the prorogations. Still such cases are but rare, because human nature in general is not subjected to the extremity either of good or evil, but rather to their moderate alteration and counter-change.

The prorogatory places must, therefore, be separately distinguished in the mode before pointed out; and the planets meeting the prorogations must again be all taken into consideration: not only those which may be anæretic (as in the case of the duration of life), nor those only which may be configurated bodily,[275] or in opposition or quartile, but also those in trine or sextile. And, first, the times in each prorogation will be governed by the planet occupying or configurated with the actual prorogatory degree itself: if, however, there be found no planet thus constituted, the nearest preceding

planet will govern the times until another, which may be in aspect to the degree following in the order of the signs, shall take them; and this one, again, will do the same until the next in succession shall take them.[276] The like rule obtains with respect to any other planets received into dominion, and with respect to those in occupation of the terms.

Further, in prorogations of the ascendant, the degrees of distances will be equal in number to the ascensional times of the particular latitude; but, in prorogation, from the mid-heaven, to the times of culmination; and, in other prorogations, they will be in proportion to the ascensions, or descensions, or culminations, and will depend on their proximity to the angles; as has been already said in treating of the duration of life.[277]

The arbiters of general times are to be determined by the foregoing method; but arbiters of annual periods as follows: viz. after the number of years which have elapsed since the birth has been ascertained, the amount is to be projected from each place of prorogation, in the succession of the signs, at the rate of one sign for a year,[278] and the lord[Pg 141] of the last sign[279] is to be assumed as arbiter. And, with regard to periods reckoned by months, the same rule is to be observed: for in this case also, the number of the month, as counted from the month of the nativity, is to be projected from such places as possess the dominion of the year, in the proportion of twenty-eight days per sign. So, likewise, in the case of periods reckoned by days, the number of the day, counted from the day of birth, must be projected from the monthly places of dominion, allowing for each sign two days and a third.[280]

It is, however, necessary to notice the ingresses made on places allotted to different periods; for they take effect in no small degree on the events of the period. Thus, the ingresses made by Saturn, on places of general periods, require special observation; those made by Jupiter, on places of annual periods; those made by the Sun, Mars, Venus, and Mercury, on monthly places; and the Moon’s transit over daily places. It must also be remembered, that arbiters of general periods are chiefly paramount over

the events; and that, to their influence, the arbiters of particular periods (each of whom acting by its own proper nature) present either co-operation or obstruction; and that the ingresses also operate on events, by increasing or diminishing their force and extent.[281]

The general characteristic property, and the duration of the period, will be indicated by the place of prorogation, as also by the lord of the general times, and by the planet in possession of the terms; by means of the familiarity subsisting, from the actual birth, between each planet, and the places of which they may have respectively and originally taken dominion. The arbiters of time will also give indication whether the event will be good or evil, by means of their own naturally benefic or malefic property and temperament, and by their original familiarity or variance with the place of which they have become lords. But the period, at which the event will become more [Pg 142]strongly evident, is shown by the relative positions of the annual and monthly signs towards the places wherein the causes exist, and also by the ingresses of the planets.[282]

The mode in which the Sun and Moon may be disposed, in reference to the signs relating to annual and monthly periods, is also indicative. For example, should they, from the date of the nativity, be posited in concord with the operative places, and keep a position of concord at the ingresses, they will produce good; but, if adversely posited, evil. And also, if they be not in concord with the said places, and provided they be contrary in condition, and in opposition or in quartile, to the transits, they will cause evil: should they, however, not be in quartile, nor in opposition, but otherwise configurated, their influence then will not be equally malefic.

Should it happen that the same planets may be lords of the times,[283] as well as of the ingresses, the effect will be extreme and unalloyed, if of a favourable nature; and more particularly unmitigated, if evil. And should the said planets be not only lords of the times, but likewise hold dominion from the date of the nativity, and provided also that all the prorogations, or most of them, should tend to, or depend on, one and the same place, or, should the prorogations not be so constituted, yet notwithstanding, if the

meetings occurring at the periods be found to be either all, or most of them, benefic or malefic, they will wholly produce, in all respects, good or evil fortune, respectively.

It is in this method, which preserves a natural order and succession, that times and seasons require to be contemplated.[Pg 143]

And now, in adverting to the scope allotted to this work in its commencement, all further adaptation of the forms of events liable to take effect at particular times will here be relinquished; because the operative influences which the stars exercise in all events, whether general or particular, may be arranged in proper order, if care be taken that the causes set forth by the Rules of Science, and the causes arising from any existing commixture, be duly combined and blended together.

THE END

[Pg 144]

APPENDIX

NO. I

ALMAGEST;

BOOK VIII, CHAP. IV

The various constellations of the fixed stars having now been duly described, their aspects remain to be investigated.

Independently of the steadfast and immutable aspects which the said stars preserve among themselves, either rectilinearly, or triangularly, or by other similar forms,[284] they have also certain aspects considered as referring exclusively to the

zaid n. adwan

planets and the Sun and Moon, or parts of the zodiac; certain others to the earth only; and others, again, to the earth, the planets and the Sun and Moon, or parts of the zodiac, combined.

With regard to the planets only, and parts of the zodiac, aspects are properly considered as made to them by the fixed stars, when the said planets and fixed stars may be posited on one and the same of those circles which are drawn through the poles of the zodiac; or, also, if they be posited on different circles, provided a trinal or sextile distance between them may be preserved; that is to say, a distance equal to a right angle and a third part more, or a distance equal to two-thirds of a right angle; and provided, also, that the fixed stars be on such parts of the circle as are liable to be transited by any one of the planets. These parts are situated within the latitude of the zodiac, which circumscribes the planetary motions. And as far as the five planets are concerned, the aspects of the fixed stars depend upon the visible mutual conjunctions, or configurations, made in the forms above prescribed; but, with respect to the Sun and Moon, they depend on occultations, conjunctions, and succedent risings of the stars. Occultation is when a star becomes invisible by being carried under the rays of the luminary; conjunction, when it is placed under the luminary's centre; and succedent rising, when it begins to reappear on issuing out beyond the rays.

In regard to the earth only, the aspects of the fixed stars are four in number, and are known by the common term of angles: to speak, however, more particularly, they are the oriental horizon, the meridian or mid-heaven above the earth, the occidental horizon, and the meridian or mid-heaven below the earth. And in that part of the earth where the equator is in the zenith, the whole of the fixed stars are found to rise [Pg 145]and set, and to be above as well as below the earth, once in each revolution; because the situation of the poles of the equator, being in this manner on the plane of the horizon, thereby prevents the constant visibility or invisibility of any one of the parallel circles. But in other parts of the earth, where the pole of the equator is in the zenith, the fixed stars can

zaid n. adwan

never set nor rise; because the equator itself is then on the plane of the horizon, and circumscribes the two hemispheres (which it thus creates, one above and the other below the earth) in such a manner, that in one revolution every star must twice transit the meridian, some of them above, others below the earth. In other declinations, however, between these extreme positions of the equator, as just mentioned, there are certain of the circles always visible, and others never visible; consequently, the stars intercepted between the first of such circles and the poles can neither rise not set, but must, in the course of one revolution, twice transit the meridian; above the earth, if the said stars be on a circle always visible; but below the earth, if on a circle never visible. The other stars, however, situated on the greater parallels, both rise and set, and are found in each revolution once on the meridian above the earth, and once on that below the earth. In all these cases, the time occupied in proceeding round from any angle to the same again, must be everywhere equal in its duration, for it is marked by one sensible revolution; and the time occupied in passing from either meridianal angle to the angle diametrically opposite, is also everywhere equal; because it is marked by the half of one revolution. So, also, the passage from either horizontal angle to its opposite angle is again effected in the same equal portion of time, wherever the equator may be in the zenith, for it is then likewise marked by the half of an entire revolution; because on such a position of the equator, all the parallels are then divided, as well by the horizon as by the meridian, into two equal parts. But in all other declinations, the time of passage of a semicircle above the earth is not equal to that of its passage below the earth, except only in the case of the equinoctial circle itself, which, in an oblique sphere, is the only one divided by the horizon into two equal parts, all others (its parallels) being bisected into dissimilar and unequal arcs. It follows, accordingly, that the time contained in the space between rising or setting, and either meridian, must be equal to the time between the *same* meridian and rising and setting; because the meridian divides equally such portions of the parallels as are above or under the earth. But in proceeding in an *oblique* sphere, from rising or setting to *either* meridian, the time occupied must be

Zain-adwan

unequal; and in a right sphere, equal, because the entire portions above the earth are, in a *right* sphere only, equal to those below the earth; whence, for instance, in a right sphere, whatever stars may be together on the meridian must also all rise and set together, until their progress becomes perceptible by the poles of the zodiac; while, on the other hand, in an oblique sphere, whatever stars may be together on the [Pg 146]meridian can neither all rise together nor set together; for the more southern stars must always rise later than those which are more northern, and set earlier.[285]

The aspects made by the fixed stars, in regard to the planets or parts of the zodiac, and the earth combined, are considered, in a general manner, by the rising, or meridianal position, or setting of the same fixed stars in conjunction with any planet or part of the zodiac; but their aspects are properly distinguishable, by means of the Sun, in the nine following modes:—

1. The first is called matutine subsolar, when the star is found together with the Sun in the oriental horizon. Of this aspect, one species is called the oriental, invisible, and succedent rising; when the star, at the commencement of its occultation, rises immediately after the Sun: another is called the precise oriental co-rising; when the star is found in partile conjunction with the Sun in the oriental horizon: another is the oriental, precedent, and visible rising; when the star, beginning to appear, rises before the Sun.

2. The second aspect is termed matutine location in the mid-heaven; when the star is found on the meridian, either above or below the earth, while the Sun is on the oriental horizon. And of this aspect, one species is called a succedent and oriental location in the mid-heaven, invisible; when, immediately after the Sun's rising, the star shall be found on the meridian: another is the precise oriental location in the mid-heaven; when, exactly as the Sun rises, the star is at the same time on the meridian; another is the oriental precedent location in the mid-heaven; when the star first shall come to the meridian above the earth, and the Sun may then immediately rise.

3. The third, called matutine setting, is when the Sun may be actually in the oriental horizon, but the star in the occidental. One of the forms of this aspect is called the oriental, succedent setting, invisible; when the star sets immediately after the Sun's rising: another is the precise oriental co-setting, when the star sets at the moment of the Sun's rising: another is the oriental, precedent, and visible setting, when the Sun does not rise until immediately after the setting of the star.

4. The fourth aspect is named meridianal subsolar, and takes place when the Sun is actually on the meridian, but the star on the oriental horizon. Of this, one is diurnal and invisible; when the star rises while the Sun is posited on the meridian above the earth: another is nocturnal and visible; when the star rises while the Sun is placed on the meridian below the earth.

5. The fifth is called meridianal location in the mid-heaven; when the Sun, as well as the star, may be at the same time on the meridian. Of this aspect, two sorts are diurnal and invisible; when the star is on the meridian above the earth, together with the Sun, or on that below [Pg 147]the earth, diametrically opposite to the Sun. Two also are nocturnal, and of these, one is invisible; when the star is on the meridian under the earth, together with the Sun: the other, however, is visible; when the star is on the meridian above the earth, diametrically opposite to the Sun.

6. The sixth is meridianal setting; when the star is found on the occidental horizon, while the Sun is on the meridian. Of this, one species is diurnal and invisible; when the star sets while the Sun is above the earth on the meridian: the other is nocturnal and visible; when the star sets while the Sun is on the meridian below the earth.

7. The seventh aspect is called vespertine subsolar; when the star is found on the oriental horizon, while the Sun is posited on the occidental horizon. One form of this aspect is the vespertine succedent rising, visible; when the star rises immediately after sunset: another is the precise vespertine co-rising; when the star rises and the Sun sets

at one and the same time: another is the precedent, vespertine rising, invisible; when the star rises immediately before the Sun sets.

8. The eighth is named vespertine location in the mid-heaven; when the star is on the meridian, either above or below the earth, while the Sun is placed on the occidental horizon. Of this aspect, one kind is called a visible vespertine location in the mid-heaven; when the star is found there immediately after sunset: another is the precise vespertine location in the mid-heaven; when the star is found there at the moment of sunset; another is the vespertine precedent location in the mid-heaven, invisible; when the star arrives there immediately before sunset.

9. The ninth aspect is called vespertine setting; when the star, together with the Sun, is on the occidental horizon. One form of this aspect is the vespertine, succedent and visible setting; when the star, at the commencement of its occultation, sets immediately after the Sun: another is the precise vespertine setting; when the star sets at the same moment with the Sun: another is the precedent, invisible setting; when the star, before it emerges from its occultation, sets before the Sun.

NO. II

ALMAGEST; BOOK II.

EXTRACT FROM CHAP. IX

Of Circumstances regulated by Ascensions

In any climate whatever, the magnitude of a given day or night is to be computed by the number of ascensional times proper to that particular climate. For example, the magnitude of the day will be ascertained by numbering the times between the Sun's zodiacal degree and the degree [Pg 148]diametrically opposite, in the succession of the

zaid n. adwan

signs; and that of the night, by numbering the times, from the degree diametrically opposite to the Sun, onwards, in the order of the signs, to be the degree actually occupied by the Sun: because, by dividing the respective amounts of these times so obtained, by fifteen, the number of equatorial hours belonging to each space will be exhibited; and if the division be made by twelve, instead of fifteen, the result will show the numbers of degrees equivalent to one temporal hour of either of the said spaces respectively.[286]

The magnitude of any temporal hour may be, however, more easily found by referring to the annexed Table of Ascensions, and taking the difference between the respective aggregate numbers, inserted therein under the heads of the equinoctial parallel or right sphere, and of any particular climate for which the magnitude of the temporal hour is required; and, if the said hour be a diurnal hour, the aggregate times as stated against the zodiacal degree occupied by the Sun; but, if nocturnal, those stated against the degree diametrically opposite, are to be compared; and the sixth part of the difference between them is to be added, if the said degree be in the northern signs, to the fifteen times of an equatorial hour; but subtracted therefrom, if in the southern signs. The amount thus obtained will be the required number of degrees of the temporal hour in question.[287]

[Pg 149]And if it be required to reduce the temporal hours of any given day or night, in a certain climate, into equatorial hours, they must be multiplied by their proper horary times, whether diurnal or nocturnal, as the case may be; the product is then to be divided by fifteen, and the quotient will necessarily be the number of equatorial hours in the climate in question, on the given day or night.[288] On the other hand, equatorial hours are also to be reduced into temporal hours by being multiplied by fifteen, the product of which is to be divided by the horary times proper to the given day or night in the said climate.

The degree ascending in the ecliptic, at any given temporal hour, may also be ascertained by multiplying the number of temporal hours since sunrise, if the given hour be diurnal, but if nocturnal, since sunset, by their proper horary times; and the product is to be added, in the succession of the signs, to the aggregate number (as shown by the ascensions proper to the climate) of the Sun's degree, if the given hour be diurnal, but, if nocturnal, to that of the degree diametrically opposite, and that particular degree of the ecliptic which shall correspond with the total number thus found in the ascensions of the climate will be the degree then ascending.[289]

But, in order to ascertain the degree on the meridian above the earth, the number of temporal hours since the preceding noon are also to be multiplied by their proper horary times, and the product is to be added to the aggregate number of the Sun's right ascension; and that degree of the ecliptic, with which the total number as found in the aggregate [Pg 150]times of right ascension shall correspond, will then be on the meridian.[290] The degree on the oriental horizon will, however, also show what degrees occupy the meridian; for, by subtracting 90 times (the amount of the quadrant) from the aggregate number ascribed to the said ascending degree in the Table proper to the climate, the number so reduced will be found, in the aggregate times of the Table of Right Ascension, to correspond with the degree on the meridian. And again, on the other hand, by adding 90 to the aggregate times ascribed by right of ascension to the degree on the meridian above the earth, the degree ascending may be obtained, for it will be that degree which corresponds to that total number, as stated in the Table proper to the climate.[291]

The Sun always preserves an equal distance in equatorial hours from all parts of the same meridian; but his distance in equatorial hours from different meridians varies according to the degrees of distance between meridian and meridian.

The foregoing extracts have been made to show the entire agreement between the astronomy of the Tetrabiblos and that of the Almagest. The Tables herein given from

Zaid H. Adwan

the latter work are, of course, now, in some degree, superseded by others of modern calculation, infinitely more complete.[Pg 151]

[Pg 153]

NO. III

THE CENTILOQUY,

OR

HUNDRED APHORISMS OF CLAUDIUS PTOLEMY[294];

OTHERWISE CALLED,

THE FRUIT OF HIS FOUR BOOKS

I. Judgment must be regulated by thyself, as well as by the science; for it is not possible that particular forms of events should be declared by any person, however scientific; since the understanding conceives only a certain general idea of some sensible event, and not its particular form. It is, therefore, necessary for him who practices herein to adopt inference. They only who are inspired by the deity can predict particulars.

II. When an enquirer shall make mature search into an expected event, there will be found no material difference between the event itself and his idea of it.

III. Whosoever may be adapted to any particular event or pursuit, will assuredly have the star indicative thereof very potent in his nativity.

IV. A mind apt in knowledge will discover truth more readily than one practised in the highest branches of science.

zain.adwan

V. A skilful person, acquainted with the nature of the stars, is enabled to avert many of their effects, and to prepare himself for those effects before they arrive.

VI. It is advantageous to make choice of days and hours at a time well constituted by the nativity. Should the time be adverse, the choice will in no respect avail, however favourable an issue it may chance to promise.

VII. The mingled influences of the stars can be understood by no one who has not previously acquired knowledge of the combinations and varieties existing in nature.

VIII. A sagacious mind improves the operation of the heavens, as a skilful farmer, by cultivation, improves nature.

[Pg 154]

IX. In their generation and corruption forms are influenced by the celestial forms, of which the framers of talismans consequently avail themselves, by observing the ingresses of the stars thereupon.

X. In the election of days and hours, make use of the malefics, to the same moderate extent as the skilful physician would use poisons in order to perform cures.

XI. A day and hour are not to be elected until the quality of the object proposed shall be known.

zaid n. adwan

XII. Love and hatred prohibit the true accomplishment of judgments; and, inasmuch as they lessen the most important, so likewise they magnify the most trivial things.

XIII. In every indication made by the constitution of the heavens, secondary stars, whether auxiliary or injurious thereto, are also to be used.

XIV. The astrologer will be entangled in a labyrinth of error, when the seventh house and its lord shall be afflicted.

XV. Signs cadent from the ascendant of any kingdom are the ascendants of that kingdom's enemies. But the angles and succedent houses are the ascendants of its friends. It is the same in all doctrines and institutions.

XVI. When the benefics may be controlled in the eighth house, they bring mischief by means of good men: if, on the other hand, they be well affected, they will prevent mischief.

XVII. Give no judgment as to the future life of an aged person, until the number of years he may live shall have been reckoned.

XVIII. If, while a benefic may ascend, both the luminaries should be in the same minute[295], the native will be equally and highly prosperous in all things which can befall him. So, likewise, if the luminaries be mutually opposed by the east and west. But the

zain adwan

contrary effect will be produced, should a malefic be on the ascendant.

XIX. The efficacy of purgation is impeded by the Moon's conjunction with Jupiter.

XX. Pierce not with iron that part of the body which may be governed by the sign actually occupied by the Moon.

XXI. When the Moon may be in Scorpio or Pisces, purgation may be advantageously used, provided the lord of the ascendant be coupled with some star posited below the earth. If he be coupled with a star placed above the earth, the potion swallowed will be vomited up.

XXII. Neither put on nor lay aside any garment for the first time, when the Moon may be located in Leo. And it will be still worse to do so, should she be badly affected.

[Pg 155]

XXIII. Aspects between the Moon and stars give the native much activity; and, if the stars be in power, they indicate an efficient, but if weak an inert, excitation to action.

XXIV. An eclipse of the luminaries, if in the angles of the nativity, or of an annual revolution, is noxious; and the effects take place according to the space between the ascendant and the place of eclipse. And

zaid n. adwan

as, in a solar eclipse, a year is reckoned for an hour, so likewise, in a lunar eclipse, a month is reckoned for an hour.

XXV. The progression of a significator, posited in the mid-heaven, is to be made by right ascension; of another posited in the ascendant, by the oblique ascension of the particular latitude.

XXVI. There is obvious concealment in the case, if the star significative of any particular affair be in conjunction with the Sun, either under the earth or in a place foreign to its own nature. On the other hand, there is manifestation, should the star be raised to elevation out of its depression, and be located in its own place.

XXVII. Venus gives pleasure to the native in that part of the body which may be ruled by the sign she occupies. It is the same with other stars.

XXVIII. When the Moon may not hold a familiarity with two planets, as is desirable, care should be taken to connect her, if possible, with some fixed star combining their qualities.

XXIX. The fixed stars grant extremely good fortune, unconnected with the understanding; but it is most commonly marked by calamities, unless the planets also agree in the felicity.

zain adwan

XXX. Observe the creation of the first king of any dynasty; for if the ascendant at that creation should agree with the ascendant of the nativity of the king's son, he will succeed his father.

XXXI. When the star ruling over any kingdom shall enter into a climacterical place, either the king, or some one of the chief men of his kingdom, will die.

XXXII. Concord between two persons is produced by an harmonious figuration of the stars, indicative of the matter whereby good will is constituted, in the nativity of either person.

XXXIII. Love and hatred are discernible, as well from the concord and discord of the luminaries, as from the ascendants of both nativities: but obeying signs increase good will.

XXXIV. If the lord of the place of the new Moon be in an angle, he is indicative of the events liable to happen in that month.

XXXV. When the Sun arrives at the place of any star, he excites the influence of that star in the atmosphere.

XXXVI. In the foundation of cities, consider the fixed stars which may seem to contribute thereto; but in the erection of houses, observe the planets. The kings of every city which has Mars in culmination will most commonly perish by the sword.

[Pg 156]

zain adwan

XXXVII. If Virgo or Pisces be on the ascendant, the native will create his own dignity; but if Aries or Libra is on the ascendant, he will cause his own death. The other signs are to be contemplated in the same way.

XXXVIII. Mercury, if established in either house of Saturn, and in power, gives the native a speculative and inquisitive intellect: if in a house of Mars, and especially if in Aries, he gives eloquence.

XXXIX. Affliction of the eleventh house, in the creation of a king, indicates damage in his household and his treasury: affliction of the second house denotes the detriment of his subject's wealth.

XL. When the ascendant is oppressed by the malefics, the native will delight in sordid things, and approve ill-favoured odours.

XLI. Beware the affliction of the eighth house and its lord, at a time of departure; and that of the second house and its lord, at a time of return.

XLII. Should a disease begin when the Moon may be in a sign occupied at the birth by some malefic, or in quartile or opposition to any such sign, such disease will be most severe; and if the malefic also behold the said sign, it will be dangerous. On the other hand, there will be no danger if the Moon be in a place held at the time of birth by some benefic.

zain.adwan

XLIII. The malefic figures of a nation are strengthened by adverse figurations of existing times.

XLIV. It is an evil case if the ascendant of a sick person resist the figuration of his own nativity; and if the time should not bring up any benefic.

XLV. If the ascendant, or principal significators, be not in human signs, the native himself will be also estranged from human nature.

XLVI. In nativities much happiness is conferred by the fixed stars; and also by the angles of the new Moon, and by the place of a kingdom's Part of Fortune, should the ascendant be found in any of them.

XLVII. If a malefic in one nativity fall on the place of a benefic in another nativity, he who has the benefic will suffer damage from him who has the malefic.

XLVIII. If the mid-heaven of a prince be the ascendant of his subject, or if their respective significators be configurated in a benevolent form, they will continue long inseparable. It will be the same, also, should the sixth house of a subject or servant be the ascendant of his prince or master.

[Pg 157]

XLIX. If the ascendant of a servant be the mid-heaven in his master's nativity, the master will place so much confidence in that servant as to be ruled by him.

zain.adwan

L. Overlook none of the hundred and nineteen conjunctions; for on them depends the knowledge of worldly operations, whether of generation or of corruption.

LI. Make the sign occupied by the Moon at the time of birth the sign ascending at the conception; and consider that in which she may be posited at the conception, or the opposite one, as the sign ascending at the birth.

LII. Men of tall stature have their lords of nativity in elevation, and their ascendants in the beginnings of signs; but the lords of men of short stature will be found in declination.[296] It must also be seen whether the signs be right or oblique.

LIII. The lords of nativity of slight or thin men have no latitude, but those of stout or fat men have; and, if the latitude be south, the native will be active; if north, inactive.

LIV. In the construction of a building, the principal rulers, if coupled with a star below the earth, will impede the erection.

LV. Mars' evil influence over ships is diminished if he be neither in the mid-heaven nor in the eleventh house; but if in either of those places, he renders the ship liable to be captured by pirates. And if the

zain adwan

ascendant be afflicted by any fixed star of the nature of Mars, the ship will be burned.

LVI. While the Moon is in her first quarter, withdrawing from her conjunction with the Sun, the bodily humours expand until her second quarter: in her other quarters they decrease.

LVII. If, during a sickness, the seventh house and its lord be afflicted, change the physician.

LVIII. Observe the place of an aspect, and its distance from the ascendant of the year; for the event will happen when the profection may arrive thither.

LIX. Before pronouncing that an absent person shall die, observe whether he may not become intoxicated; before declaring that he shall receive a wound, see whether he may not be let blood; and before saying that he shall find treasure, examine whether he may not receive his own deposit; for the figures of all these things may be similar.

LX. In cases of sickness, observe the critical days, and the Moon's progress in the angles of a figure of sixteen sides. If those angles be well affected, it is favourable for the invalid; if they be afflicted, unfavourable.

[Pg 158]

LXI. The Moon is significative of bodily matters, which, in respect of motion, resemble her.

zaid n. adwan

LXII. By marking exactly the beginning of a conjunction,[297] judgment may be made of the variation of the weather in the ensuing month. It will depend upon the lord of the angle of every figure, for he controls the nature of the atmosphere; assuming also at these times the quality of the existing weather.

LXIII. In the conjunction of Saturn and Jupiter, pronounce according to the nature of that one which may be higher in elevation. Follow the same rule with other stars.

LXIV. After ascertaining the lord of the inquiry, see what power he may have in the annual revolution, or in the ascendant of the new Moon; and pronounce accordingly.

LXV. In the least conjunction, the difference of the mean conjunction, and in the mean conjunction the difference of the greatest conjunction.[298]

LXVI. Consider no profection by itself alone, but make reference also to the qualifications and impediments of the stars.

LXVII. Years are diminished by the imbecility of the receiver.

LXVIII. A malefic, when matutine, signifies an accident; when vespertine, a disease.

LXIX. The native's sight will be impaired if the Moon be opposed to the Sun, and joined with nebulous stars;

zain adwan

and if the Moon be in the western angle, and both the malefic stars in the eastern angle, the Sun being in an angle also, the native will become blind.

LXX. Insanity is produced if the Moon have no connection with Mercury; and, if neither of them be connected with the ascendant, Saturn being in occupation of the angle by night, but Mars by day, especially if in Cancer, Virgo, or Pisces, a dæmoniac affection will be produced.

LXXI. If both luminaries may be in masculine signs, in the nativities of males, their actions will be consonant with nature; but if so placed in the nativities of females, they increase their action. And Mars and Venus, if matutine, incline to the masculine gender; if vespertine, to the feminine.

LXXII. Matters of education are to be considered by the ascending lords of triplicity; matters of life, by the lords of the conditionary luminary's triplicity.

[Pg 159]

LXXIII. If the Sun be found with the Gorgon's head (*Caput Medusæ*), and not aspected by any benefic star, and if there be no benefic present in the eighth house, and the lord of the conditionary luminary be opposed to Mars, or in quartile to him, the native will be beheaded. If the luminary culminate, his body will be maimed or mangled; and if the aspect in quartile

zain.adwan

be from Gemini or Pisces, his hands and feet will be amputated.

LXXIV. Mars, if ascending, uniformly gives a scar in the face.

LXXV. If the Sun be in conjunction with the lord of the ascendant, in Leo, and Mars has no prerogative in the ascendant, and if there be no benefic in the eighth house, the native will be burned.

LXXVI. If Saturn hold the mid-heaven, and the conditionary luminary be opposed to him, the native will perish in the ruins of buildings, provided the sign on the lower heaven be an earthly sign; if it be a watery sign, he will be drowned or suffocated by water: if a human sign, he will be strangled by men, or will perish by the halter or the scourge. Should there, however, be a benefic in the eighth house, he will not suffer death, although he will be brought near it.

LXXVII. Profection of the ascendant is to be made for matters affecting the body; of the Part of Fortune, for extrinsic circumstances; of the Moon, for the connection between the body and the spirit; and of the mid-heaven, for the employment or profession.

LXXVIII. A star often dispenses influence in a place in which it has no prerogative, thus bringing unexpected advantage to the native.

zaid n. adwan

LXXIX. Whoever has Mars in the eleventh house, does not govern his master.

LXXX. If Venus be in conjunction with Saturn, and have any lord of house in the seventh house, the native will be of spurious origin.

LXXXI. Times are reckoned in seven ways; viz. by the space between two significators; by the space between their mutual aspects; by the approach of one to the other; by the space between either of them and the place appropriated to the proposed event; by the descension of a star, with its addition or diminution; by the changing of a significator; and by the approach of a planet to its place.

LXXXII. When a figure may be equipoised, observe the horoscope (or figure) at the new or full moon, and, if that also be equipoised, be not hasty in giving judgment.

LXXXIII. The time of obtaining a grant indicates the affection between the applicant and his prince; but the seat[299] shows the nature of the office;—

[Pg 160]

LXXXIV. And if Mars be lord of the ascendant at the time of entering on possession, and posited in the second house, or coupled with the lord of the second, he brings much mischief.

zain n. adwan

LXXXV. Should the lord of the ascendant be configurated with the lord of the second house, the prince will spontaneously create many charges.

LXXXVI. The Sun is the source of the vital power; the Moon, of the natural power.

LXXXVII. Monthly revolutions are made in twenty-eight days, two hours and about eighteen minutes. Judgment is also made by some persons by means of the Sun's progress; that is to say, by his partial equations to that degree and minute which he might hold at the beginning.

LXXXVIII. In making profection of the part of Fortune for a whole annual revolution, a space equal to that between the Sun and Moon is to be reckoned from the ascendant.

LXXXIX. Consider the grandfather's affairs from the seventh house and the uncle's from the sixth.

XC. Should the significator be in aspect to the ascendant, the hidden event or object will correspond in its nature with the ascendant; but if the ascendant be not so aspected, the nature of the event will accord with that of the place in which the significator is posited. The lord of the hour shows its colour; the place of the Moon its time; and, if above the earth, it will be a novel thing; if below, old. The part of Fortune indicates its quantity, whether long or short. The lords

Zain Adwan

of the terms, and of the lower heaven and mid-heaven, and of the Moon, shows its substance or value.

XCI. Should the ruler of a sick person be combust, it is an evil portent; and especially if the part of Fortune be afflicted.

XCII. Saturn, if oriental, is not so highly noxious to a sick person; nor Mars, if occidental.

XCIII. Judgment is not to be drawn from any figure until the next conjunction shall have been considered: for principles are varied by every conjunction; and therefore, to avoid error, both the last and the next should be combined.

XCIV. The place of the more potent significator indicates the thoughts of the inquirer.

XCV. The stars rising with the tenth house prove how far the native may be fitted to the occupation which he follows.

XCVI. In an eclipse, such significations as are made nearest the angles, show the events decreed. The nature of the stars in accordance with the eclipse, plants as well as fixed stars, and also the appearances co-ascending, are likewise to be considered, and judgment is to be given accordingly.

[Pg 161]

zaid n. adwan

XCVII. The event inquired about will be speedily accomplished, should the lord of the new or full Moon be in an angle.

XCVIII. Shooting stars, and meteors like flowing hair, bear a secondary part in judgments.

XCIX. Shooting stars denote the dryness of the air; and, if they are projected to one part only, they indicate wind therefrom: if to various parts, they indicate diminution of waters, a turbulent atmosphere, and incursions of armies.

C. If comets, whose distance is eleven signs behind the Sun, appear in angles, the king of some kingdom, or one of the princes or chief men of a kingdom, will die. If in a succedent house, the affairs of the kingdom's treasury will prosper, but the governor or ruler will be changed. If in a cadent house, there will be diseases and sudden deaths. And if comets be in motion from the west towards the east, a foreign foe will invade the country: if not in motion, the foe will be provincial, or domestic.

END OF THE CENTILOQUY

NO. IV

THE ZODIACAL PLANISPHERE

zain.adwan

The Reader is desired to refer to the Plate at end of book containing diagrams of the Zodiacal Planisphere, which has been spoken of in the Note in p. 99.

Fig. 1 is the Planisphere adjusted for the northern latitude of 30° 22′ (where the longest day consists of fourteen equatorial hours), agreeably to the "Exemplification" given by Ptolemy in Chapter XV, Book 3. It represents that portion of the celestial sphere which is contained between the tropics: the central horizontal line is the equator; the curved line extending longitudinally from east to west is the ecliptic; the central perpendicular line is the meridian, or cusp of the 10th house; the other short lines, cutting the equator transversely, are the cusps of the other houses; that of the 1st house being the eastern horizon; that of the 7th, the western horizon. Hence, the distance from the 1st house to the meridian, or from the meridian to the 7th house, shows the semi-diurnal arc of any parallel of declination in the ecliptic; and the distance of the 7th house to the 4th, or from the 4th to the 1st, shows the semi-nocturnal arc. The distance from the cusp of one house to that of the next, taken on the [Pg 162]same parallel, is also equal to two temporal hours; thus, for instance, in the latitude above quoted, the semi-diurnal arc of 0° ♊ is 6 h. 50 m., or 102° 39′ of the equator; consequently the diurnal temporal hour is equal to one equatorial hour and eight minutes, or to 17° 6′ of the equator.

In his first example, Ptolemy directs 0° ♉ to be placed on the ascendant, so that the beginning of ♑ may be on the mid-heaven; 0° ♊ must, therefore, fall on the point A, distant from the mid-heaven 147° 44′ of the equator, as measured by the line AB; because every point in the sphere always preserves one and the same parallel with the equator; and 0° ♊, in passing to the mid-heaven, must proceed along the line AB. In the present case, however, it is required to know how long 0° ♊ will be in coming to the ascendant, the given position of 0° ♉. Now 0° ♊ will be on the ascendant when it arrives at the point G; therefore the distance from A to C is the amount of the prorogation between 0° ♉ (when posited on the ascendant) and 0° ♊, and it is equal

to 45° 5′ of the equator. In the second example, 0° ♉ is placed on the mid-heaven, which position must be at D, so that 0° ♊ must necessarily be at E; and the distance from E to B, equal to 57° 44′ of the equator, is the prorogation between 0° ♉ and 0° ♊, when 0⁴ ♉ is on the mid-heaven. In the third example, 0° ♉ is supposed to be on the 7th house, descending, at F, so that ♓ is on the mid-heaven, and 0° ♊ at the point G, in advance of the mid-heaven 32° 16′ of the equator, as shown by the distance BG. Now it is required to bring 0° ♊ to the 7th house (the place of 0° ♉), and it will be there on arriving at H, distant from B 102° 39′ of the equator; but as 0° ♊ is already at G, the distance from G to H, equal to 70° 23′ of the equator, is the amount of the prorogation between 0° ♉ and 0° ♊, when 0° ♉ is on the 7th house. The fourth example places 0° ♉ at I, three temporal hours past the meridian; 0° ♊ therefore falls on the point K, at the distance of 13 equatorial degrees before the meridian or mid-heaven, and will be three temporal hours past the meridian (the position of 0° ♉) on arriving at L, distant 51 equatorial degrees from the mid-heaven: the whole distance from K (the first position of 0° ♊) to L, its second position, equal to 64 degrees of the equator, is therefore the prorogation between 0° ♉ and 0° ♊, when 0° ♉ is past the meridian at the distance of three temporal hours. Ptolemy has also instanced two other positions for 0° ♉; viz. at two temporal hours past the meridian, and at two temporal hours before the occidental angle; or, in other words, on the cusp of the 9th house, and on that of the 8th. Now, if 0° ♉ be on the cusp of the 9th house, it must be at M, and 0° ♊ will be at N, distant 62 equatorial degrees from Q, which is also on the cusp of the 9th. If 0° ♉ be on the cusp of the 8th, it must be at O, and 0° ♊ will be at P, distant 66 equatorial degrees from R, which is also on the cusp of the 8th: these two several numbers of degrees will be the respective prorogations between 0° ♉ and 0° ♊, when 0° ♉ is placed on the 9th and 8th houses.[Pg 163]

Ptolemy's "Exemplification" has been followed thus minutely in order to show how perfectly Mr. Ranger's invention is adapted to assist (if not to supersede) arithmetical calculation; for, after the Planisphere has once been accurately laid down, a line drawn parallel to the equator, from the significator to the promittor, or to the promittor's pole of position, and measured by degrees of the equator, will accomplish the whole operation of ascertaining the amount of prorogation.

Fig. 2 is the Equator extended, *in plano*, on a scale proportionate to the planispheres in Figs. 1 and 3: it is divided into 360 degrees, and into equal time, as measured by the 24 hours of the earth's daily rotation on its axis, and by smaller portions of four minutes each, corresponding with degrees of the equator.

Fig. 3 is the Planisphere set for the latitude of Southern Britain, 51° 30′ N., where the longest day is 16 h. 30 m., the semi-diurnal arc of 0° ♊ being consequently 7 h. 52 m., or 118° of the equator, and its diurnal temporal hour equal to one hour and nearly nineteen minutes of equatorial time, or to 19° 40′ of the equator. In applying Ptolemy's examples, given in Chapter XV, Book 3, to this latitude, it will follow that, when 0° ♉ may be on the ascendant, 0° ♊ will be at A, and will subsequently arrive at the ascendant at C, after the passage of 29° 43′ of the equator. When 0° ♉ may be on the mid-heaven at D, 0° ♊ will be at E, and will arrive at B, on the mid-heaven, after the passage of 57° 44′ of the equator, as in Fig. 1. When 0° ♉ may be on the 7th house, at F, 0° ♊ will be at G, and will come to the 7th house, at H, after the passage of 85° 45′ of the equator. If 0° ♉ be three temporal hours past the meridian, at I, 0° ♊ would be at K, again 13 equatorial degrees before the meridian, as in Fig. 1, and will be three temporal hours past the meridian, a position similar to that assumed for 0° ♉, on arriving at L, distant from the mid-heaven 59 equatorial degrees; thus making the whole distance, from K to L, 17 equatorial degrees. If 0° ♉ be on the 9th house, at M, 0° ♊ will be at N, distant from Q (also on the 9th house) about 67 equatorial degrees. If 0°

♉ be on the 8th house, at O, 0° ♊ will be at P, distant from R (also on the 8th house) about 76 equatorial degrees.

By taking the trouble to calculate the distances between the several positions given by Ptolemy, the Reader may satisfy himself of the sufficiency of this Planisphere for the purpose for which it was first projected; viz. for the more expeditious measurement of the arcs of direction. The Tables of Ascensions, extracted from the Almagest, in p. 152, will show that the arcs, as measured in Figs. 1 and 2 of the plate, exactly tally with the amounts of distance obtained by calculating arithmetically, according to the respective latitudes, as quoted in the Tables.

The slight view which has been here given of the Zodiacal Planisphere invented by Mr. Ranger, must not be considered as pretending to offer a [Pg 164]complete idea of its powers: they are so manifold and various, that another volume would be required to detail them fully; and it has now been used only in order to give a better illustration of Ptolemy's examples of the spaces of prorogation than mere words can do. To persons conversant with the mathematical part of astronomy, the facility with which a complete representation of zodiacal latitude, declination, the poles of position, crepusculine circles, and other phenomena, may be made by this Planisphere, will be sufficiently obvious from the accompanying Figures.

FINIS

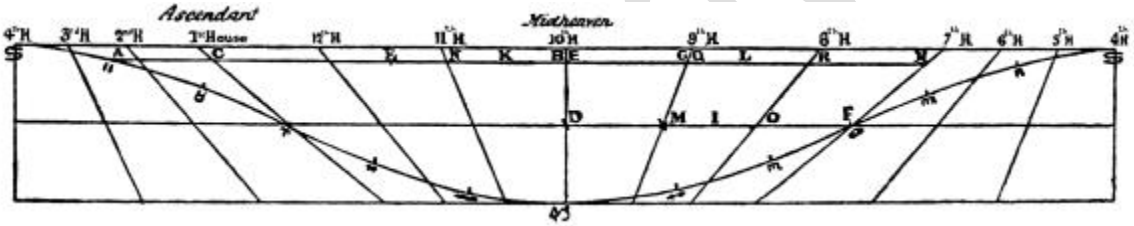
Fig. 3.



Footnotes:

[1]Sir Isaac Newton has the following remarks in regard to the origin of Astrology:—"After the study of Astronomy was set on foot for the use of navigation, and the Ægyptians, by the heliacal risings and settings of the stars, had determined the length of the solar year of 365 days, and by other observations had fixed the solstices, and formed the fixed stars into asterisms, all which was done in the reigns of Ammon, Sesac, Orus, and Memnon," (about 1000 years before Christ), "it may be presumed that they continued to observe the motions of the planets, for they called them after the names of their gods; and Nechepsos, or Nicepsos, King of Sais," (772 B.C.), "by the assistance of Petosiris, a priest of Ægypt, invented astrology, grounding it upon the aspects of the planets, and the qualities of the men and women to whom they were dedicated;† and in the

beginning of the reign of Nabonassar, King of Babylon, about which time the Æthiopians, under Sabacon, invaded Ægypt" (751 B.C.), "those Ægyptians who fled from him to Babylon, carried thither the Ægyptian year of 365 days, and the study of astronomy and astrology, and founded the æra of Nabonassar, dating it from the first year of that king's reign" (747 B.C.), "and beginning the year on the same day with the Ægyptians for the sake of their calculations. So Diodorus: '*they say that the Chaldæan in Babylon, being colonies of the Ægyptians, became famous for astrology, having learned it from the priests of Ægypt.*'"—Newton's Chronology, pp. 251, 252.

Again, in p. 327: "The practice of observing the stars began in Ægypt in the days of Ammon, as above, and was propagated from thence, in the reign of his son Sesac, into Afric, Europe, and Asia, by conquest; and then Atlas formed the sphere of the Libyans" (956 B.C.), "and Chiron that of the Greeks (939 B.C.); and the Chaldæans also made a sphere of their own. But astrology was invented in Ægypt by Nichepsos, or Necepsos, one of the Kings of the Lower Ægypt, and Petosiris his priest, a little before the days of Sabacon, and propagated thence into Chaldæa, where Zoroaster, the legislator of the Magi, met with it: so Paulinus;

'*Quique magos docuit mysteria vana Necepsos.*'"

The arcana of Astrology constituted a main feature in the doctrines of the Persian Magi; and it further appears, by Newton's Chronology, p. 347, that Zoroaster (although the æra of his life has been erroneously assigned to various remoter periods) lived in the reign of Darius Hystaspis, about 520 B.C., and assisted Hystaspes, the father of Darius, in reforming the Magi, of whom the said Hystaspes was Master. Newton adds, p. 352, that "about the same time with Hystaspes and Zoroaster, lived also Ostanes, another eminent Magus: Pliny places him under Darius Hystaspis, and Suidas makes him the follower of Zoroaster: he came into Greece with Xerxes about 480 B.C., and seems to be the Otanes of Herodotus. In his book, called the Octateuchus, he taught the same doctrine of the Deity as Zoroaster."

Having quoted thus far from Newton, it seems proper to subjoin the following extract from the "Ancient Universal History:"—"In the reign of Gushtasp" (the oriental name of Darius Hystaspis), "King of Persia, flourished a celebrated astrologer, whose name was Gjamasp, surnamed Al Hakim, or the wise. The most credible writers say that he was the brother of King Gushtasp, and his confidant and chief minister. He is said to have predicted the coming of the Messiah; and some treatises under his name are yet current in the East. Dr. Thomas Hyde, in speaking of this

philosopher, cites a passage from a very ancient author, having before told us that this author asserted there had been among the Persians ten doctors of such consummate wisdom as the whole world could not boast the like. He then gives the author's words: 'Of these, the sixth was Gjamasp, an astrologer, who was counsellor to Hystaspis. He is the author of a book intitled *Judicia Gjamaspis*, in which is contained his judgment on the planetary conjunctions. And therein he gave notice that Jesus should appear; that Mohammed should be born; that the Magian religion should be abolished, etc.; nor did any astrologer ever come up to him.' (*E. lib. Mucj. apud Hyde.*) Of this book there is an Arabic version, the title of which runs thus: The Book of the Philosopher Gjamasp, containing Judgments on the Grand Conjunctions of the Planets, and on the Events produced by them. This version was made by Lali; the title he gave it in Arabic was Al Keranai, and he published it A.D. 1280. In the preface of his version it is said that, after the times of Zoroaster, or Zerdusht, reigned Gushtasp, the son of Lohrasp,†† a very powerful prince; and that in his reign flourished in the city of Balch, on the borders of Chorassan, a most excellent philosopher, whose name was Gjamasp, author of this book; wherein is contained an account of all the great conjunctions of the planets which had happened before his time, and which were to happen in succeeding ages; and wherein the appearances of new religions and the rise of new monarchies were exactly set down. This author, throughout his whole piece, styles Zerdusht, or Zoroaster, our Prophet. (D'Herbelot, Bibl. Orient. Art. Gjamasp.) The notion of predicting the rise and progress of religions from the grand conjunctions of the planets, has been likewise propagated in our western parts: Cardan was a bold assertor of this doctrine. The modern Persians are still great votaries of astrology, and although they distinguish between it and astronomy, they have but one word to express astronomer and astrologer; viz. *manegjim*, which is exactly equivalent to the Greek word αςτρολογος. Of all the provinces of Persia, Chorassan is the most famous for producing great men in that art; and in Chorassan there is a little town called Genabed, and in that town a certain family which, for 6 or 700 years past, has produced the most famous astrologers in Persia; and the king's astrologer is always either a native of Genabed, or one brought up there. Sir John Chardin affirms that the appointments in his time for these sages amounted to six millions of French livres per annum.—Albumazar of Balch scholar of Alkendi, a Jew, who was professor of judicial astrology at Bagdad, in the Caliphate of Almamoum††† became wonderfully famous. He wrote expressly from the Persian astrologers, and it may be from the works of Gjamasp, since he also reports a prediction of the coming of Christ in the following words: viz. 'In the sphere of

Persia, saith Aben Ezra, there ariseth upon the face of the sign Virgo a beautiful maiden, she holding two ears of corn in her hand, and a child in her arm: she feedeth him, and giveth him suck, &c. This maiden,' saith Albumazar, 'we call Adrenedefa, the pure Virgin. She bringeth up a child in a place which is called Abrie (the Hebrew land), and the child's name is called Eisi (Jesus).' This made Albertus Magnus believe that our Saviour, Christ, was born in Virgo; and therefore Cardinal Alliac, erecting our Lord's nativity by his description, casteth this sign into the horoscope. But the meaning of Albumazar was, saith Friar Bacon, that the said virgin was born, the Sun being in that sign, and so it is noted in the calendar; and that she was to bring up her son in the Hebrew land. (Mr. John Gregory's Notes on various Passages of Scripture.)"—*Ancient Universal History, vol. 5, pp. 415 to 419.*

† It is maintained by astrologers, that the planets, *having been observed* to produce certain effects, were *consequently* dedicated to the several personages whose names they respectively bear.

†† This caliph reigned in the earlier part of the 9th century, and caused Ptolemy's Great Construction to be translated into Arabic, as hereafter mentioned.

††† This seems to be a mistake of the Arabian author, for Gushtasp was identical with Darius Hystaspis, and Lohrasp (otherwise Cyaxares) was father of Darius the Mede, who was overcome by Cyrus, 536 B.C.—See Newton.

[2]To this view of the case, the following remarks seem not inapplicable: they are taken from a periodical work of deserved reputation:—

"The study of astrology itself, as professing to discover, by celestial phenomena, future mutations in the elements and terrestrial bodies, ought, perhaps, not to be despised.† The theory of the tides, for example, is altogether an astrological doctrine, and, long before the days of Sir Isaac Newton, was as well understood as it is at this moment. The correspondence alleged by the ancient physicians to exist between the positions of the Moon and the stages of various diseases, is so far from being rejected by the modern faculty, that it has been openly maintained."†† The writer then recounts sundry incidents, asserted by the astrologers to be dependent on the Moon, and he adds these words: "The fact of these allegations might be so easily ascertained, that it is surprising they should still be pronounced incredible, and *denied* rather than *contradicted*."

† "Sir Christopher Heydon's Defence of Astrology, p. 2, edit. 1603."

†† "Dr. Mead on the Influence of the Sun and Moon upon Human Bodies. See also Edinb. Rev. vol. 12, p. 36—Balfour on Sol-Lunar Influence." *Blackwood's Magazine for Dec., 1821, Part 2, No. 59.*

[3]In the 51st No. of the Quarterly Review, Art. "*Astrology and Alchymy*," the following observations are made:—

"Certainly, if man may ever found his glory on the achievements of his wisdom, he may reasonably exult in the discoveries of astronomy; but the knowledge which avails us has been created solely by the absurdities which it has extirpated. Delusion became the basis of truth. Horoscopes and nativities have taught us to place the planet in its sure and silent path; and the acquirements which, of all others, now testify the might of the human intellect, derived their origin from weakness and credulity" (p. 181). Again; "Astrology, like alchymy, derives no protection from sober reason; yet, with all its vanity and idleness, it was not a corrupting weakness. Tokens, predictions, prognostics, possess a psychological reality. All events are but the consummation of preceding causes, clearly felt, but not distinctly apprehended. When the strain is sounded, the most untutored listener can tell that it will end with the key-note, though he cannot explain why each successive bar must at last lead to the concluding chord. The omen embodies the presentiment, and receives its consistency from our hopes or fears." (p. 208).

It may, perhaps, be difficult to assent to all of the propositions involved in these extracts; but there are among them some which are clearly unquestionable.

[4]This edition was printed in double columns, one containing Proclus's Greek Paraphrase, the other the Latin translation of Leo Allatius; and William Lilly (no light authority in these matters) thus wrote of it in the year 1647: "Indeed Ptolemy hath been printed in folio, in quarto, in octavo, in sixteens: that lately printed at Leyden" (where cthe Elzevirs were established) "I conceive to be most exact; it was performed by Allatius." To the said edition is prefixed an anonymous address to the reader, in Latin, and to the following effect:—

"I have reckoned it part of my duty to give you, benevolent reader, some short information as to the publication of this little work, which, having hitherto existed only in Greek,† is now, in its Latin dress, accessible to the curiosity of all persons. This Paraphrase of Proclus on the Tetrabiblos of Ptolemy was translated a few years ago by Leo Allatius, a Greek by birth, eminently skilled in the learning of his own nation, as well as in Latin literature, and already celebrated for other

writings in both languages. He lives, I have understood, in Rome, in the family of Cardinal Biscia, and holds some office in the Vatican Library. He undertook his present work, however, for his own private gratification, and that of certain friends; but when writings compiled with this view have once quitted their author's hands, it will often happen that they have also, at the same time, escaped his control. So this offspring of Allatius, having emerged from Rome, arrived at Venice, from whence it was forwarded to me by a certain great personage of illustrious rank, in order that I might cause it to be printed. The names of Ptolemy and Proclus, so celebrated among mathematicians and philosophers, besides the subject of the work itself, seemed to me a sufficient warrant for committing it to the press. Whereupon I delayed not to avail myself of the advantages I possessed in having access to our excellent and most accurate typographers, the Elzevirs, and I earnestly solicited them to publish it: they, in their love for the commonwealth of letters, took upon themselves the charge of printing it in the form you see. You will learn from it, inquisitive Reader, how much power the stars have over the atmosphere and all sublunary things: for the stars, and those brighter bodies of heaven, must not be imagined to be idle. The whole doctrine of the stars is not, however, here treated of, but only that distinct part of it which the Greeks call judicial and prognostic, and which, while confined within certain limits is as entertaining as it is useful, and is partly considered to be agreeable to nature. But should it pretend to subject to the skies such things as do not depend thereupon, and should it invite us to foresee by the stars such things as are above the weakness of our apprehension, it will assuredly deserve to be reprehended as a vain and empty art, which has been demonstrated in many learned books by the great Picus of Mirandola. The Chaldæans, Genethliacs, and Planetarians, have been always held in disrepute, because they professed to know not only more than they actually did know, but also more than is allowed to man to know. Even Ptolemy, while he employs himself in his present work upon the Doctrine of Nativities, is scarcely free from the charge of superstition and vanity: perhaps, in a Pagan, this may be forgiven; but it is hardly to be tolerated, that persons professing Christianity should be led away by such an empty study, in which there is no solid utility, and the whole pleasure of which is puerile. Finally, I warn you that some persons doubt whether this was really produced by Ptolemy††: nevertheless, it has certainly appeared to Porphyry and Proclus (who were doubtless great philosophers, although hostile to the Christian faith) to be worthy of receiving elucidation by their Commentaries upon it.††† Peruse it, however, friendly reader, with caution, having first shaken off the weakness of credulity, for the sinew of wisdom is not to believe rashly. Farewell."

In addition to the remarks made in the foregoing address regarding Leo Allatius, it may be observed that he was appointed Keeper of the Vatican Library by Pope Alexander VII, with whom he was in high favour. It is said of him, that he had a pen with which he had written Greek for forty years, and that he shed tears on losing it. Another story of him states, that the Pope had often urged him to take holy orders, that he might be advanced in the church, and one day asked him why he had not done so: "Because," said Allatius, "I would be free to marry."—"Why, then, do you not marry?"—"Because I would be free to take orders."—*Chalmer's Biographical Dictionary.*

† This assertion is applicable only to Proclus's Paraphrase. There were several prior translations of the original Tetrabiblos in Latin and Arabic; and it appears by an extract from the Bibliotheca Græca of Fabricius (which will be found in a subsequent page), that a Latin version, done from the Arabic, was printed at Venice as early as the year 1493.

†† The reader is again referred to the extract from Fabricius (inserted in a subsequent page), containing that learned person's account of this book among the other works of Ptolemy.

††† Their Commentaries were printed at Basle, in 1559.

[5]This translation from the Perugio press has been serviceable in presenting certain various readings; but it does not seem to possess any other peculiar merit. It professes to be a translation from the original text of Ptolemy; and so likewise does the translation printed at Basle, as above quoted.

[6]It appears by the printed works of this author, that he was named Didacus Placidus de Titis. He was a native of Bologna, by profession a monk, and was styled Mathematician to the Archduke Leopold William of Austria. He wrote in the earlier part of the 17th century, and his work, now cited, is considered to contain the most successful application of Ptolemy's astrological rules to practice. The original is extremely scarce; but a new English edition, by Cooper, may be had of the Publishers of this work.

[7]Printed at Basle, 1541.

[8]Chalmer's Biographical Dictionary.

[9]In France, about the beginning of the 16th century, Oronce Finé, the Royal Reader, attempted, under the patronage of Francis I, to produce an astronomical clock, in which everything moved according to the principles of Ptolemy. It was kept, about fifty years ago, in the monastery of St.

Geneviéve, at Paris. In Lilly's Catalogue of Astrological Authors, Orontius Finæus is mentioned as the writer of a work on the twelve houses of heaven, printed in Paris, 1553.

[10]*Spectacle de la Nature.*

[11]The objection which has been urged against astrology, that the signs are continually moving from their positions, cannot invalidate this conclusion. That objection has, in fact, no real existence; for Ptolemy seems to have been aware of this motion of the signs, and has fully provided for it in the 25th Chapter of the 1st Book of the Tetrabiblos. From that chapter it is clear that the respective influences he ascribes to the twelve signs (or divisions of the zodiac) were considered by him as appurtenant to the *places* they occupied, and not to the *stars* of which they were composed. He has expressly and repeatedly declared that the point of the vernal equinox is ever the beginning of the zodiac, and that the 30 degrees following it ever retain the same virtue as that which he has in this work attributed to Aries, although the stars forming Aries may have quitted those degrees: the next 30 degrees are still be accounted as Taurus, and so of the rest. There is abundant proof throughout the Tetrabiblos, that Ptolemy considered the virtues of the *constellations* of the zodiac distinctly from those of the *spaces* they occupied.

[12]The French say 813, but 827 is the date given by English chronologists.

[13]This scientific man was a Mathurine Friar, and a professor in the University of Paris: he died in 1256. It is pointed out in the Edinburgh Review, No. 68, that he was a native of Yorkshire, and his real name John Holywood, euphonized, in Paris, into Sacrobosco.

[14]Chalmers.—The Tetrabiblos was among these works.

[15]To such readers as may be curious to know in what manner this book was promulgated in Europe, after the revival of letters, the following extract from the Bibliotheca Græca of Fabricius will furnish information:—

"Lib. IV. Cap. XIV. §4. Τετραβιβλος, Συνταξις Μαθηματικη *Quadripartitum, sive quatuor libri de apotelesmatibus et judiciis astrorum, ad Syrum* (h). Græce primum editi a *Joachimo Camerario*, cum versione suâ duorum priorum librorum, et præcipuorum e reliquis locorum. Norimb. 1535, 4to.—Hinc cum versione *Phil.* Melancthonis, qui in præfat, ad Erasmum Ebnerum Senatorem Norimbergensem testatur se editionem Camerarii multis mendis purgasse, tum numeros in locis apheticis tam Græci quam Latini textus emendasse. Viderit porro Gassendus qui in Philosophia Epicuri, ubi contra Astrologos disputat. t. 2, p. 501, contendit tetrabiblon indignum esse Ptolemæi genio et subdititum. Equidem Jo. Pico

judice, l. 1, contra Astrologos, p. 285, Ptolemæus *malorum* sive Apotelesmaticorum est *optimus*."

† "Nechepsos and Petosiris are anciently spoken of, for they first explained prognostication by Astrology."

†† This was perhaps a reprint of the edition of 1635, from which the present translation has been made; unless there may have been an error of the press in stating 1654 instead of 1635, which seems probable, as the edition of 1635 is unnoticed by Fabricius.

[16]It will be seen by the preceding note, that Proclus's Paraphrase of the Tetrabiblos should properly be considered as superior to the other readings of that book; since it appears, on the authority of Fabricius, that Melancthon, after having been at the pains of correcting and republishing, in 1553 (with his own emendations), the edition of Camerarius, containing the reputed original text, still deemed it advisible, in the following year, to edit Proclus's Paraphrase. This Paraphrase must, therefore, necessarily have had claims to his attention not found in the text he had previously edited.†

† "Ptolemy addresses the book to Syrus, to whom he has also addressed all his other treatises. Some say that this name of Syrus was feigned; others, that it was not feigned, but that he was a physician, and educated in these sciences."

[17]Chalmer's Biographical Dictionary.

[18]It will, of course, be understood that this Commentary is distinct from his Paraphrase, now translated.

[19]The Almagest, or *Magna Constructio*.

[20]The following extract from an old geographical work, framed on the rules of Ptolemy, explains the system on which this action of the æther is made to depend:—

"Chap. 2. The world is divided into two parts, the elemental region and the æthereal. The elemental region is constantly subject to alteration, and comprises the four elements; earth, water, air and fire. The æthereal region, which philosophers call the fifth essence, encompasses, by its concavity, the elemental; its substance remains always unvaried, and consists of ten spheres; of

zaid n. adwan

which the greater one always spherically environs the next smaller, and so on in consecutive order. First, therefore, around the sphere of fire, GOD, the creator of the world, placed the sphere of the Moon, then that of Mercury, then that of Venus, then that of the Sun, and afterwards those of Mars, of Jupiter, and of Saturn. Each of these spheres, however, contains but one star: and these stars, in passing through the zodiac, always struggle against the *primum mobile*, or the motion of the tenth sphere; they are also entirely luminous. In the next place follows the firmament, which is the eighth or starry sphere, and which trembles or vibrates (*trepidat*) in two small circles at the beginning of Aries and Libra (as placed in the ninth sphere); this motion is called by astronomers the motion of the access and recess of the fixed stars." (Probably in order to account for the procession of the equinoxes.) "This is surrounded by the ninth sphere, called the chrystalline or watery heaven, because no star is discovered in it. Lastly, the *primum mobile*, styled also the tenth sphere, encompasses all the before-mentioned æthereal spheres, and is continually turned upon the poles of the world, by one revolution in twenty-four hours, from the east through the meridian to the west, again coming round to the east. At the same time, it rolls all the inferior spheres round with it, by its own force; and there is no star in it. Against this *primum mobile*, the motion of the other spheres, running from the west through the meridian to the east, contends. Whatever is beyond this, is fixed and immovable, and the professors of our orthodox faith affirm it to be the empyrean heaven which GOD inhabits with the elect."—Cosmographia of Peter Apianus (named Benewitz), dedicated to the Archbishop of Salzburg, edited by Gemma Frisius, and printed at Antwerp 1574.

[21]It will be recollected that the Ptolemaic astronomy attributes motion and a regular course to those stars which we now call fixed, but which the Greeks merely termed απλανεις, *undeviating*.

[22]There seems reason to suppose that this was a favourite speculation among the ancients. In Scipio's Dream, as related by Cicero, the phantom of his illustrious grandfather is made to speak of this entire return of all the celestial bodies to some original position which they once held, as being the completion of the revolution of one great universal year: and the phantom adds, "but I must acquaint you that not one-twentieth part of that great year has been yet accomplished."

This quotation is from memory, and perhaps may not be verbally correct.

[23]In this passage the author seems to have anticipated, and exposed the absurdity of an argument now considered very forcible against astrology: viz. that "if the art were true, then any two individuals born under the same meridian, in the same latitude, and at the same moment of time,

must have one and the same destiny; although one were born a prince, and the other a mendicant." Such a monstrous conclusion is nowhere authorized by any astrological writer; it is, on the contrary, always maintained by all of them, that the worldly differences and distinctions, alluded to in the text, inevitably prevent this exact resemblance of destiny; and all that they presume to assert is, that, in their respective degrees, any two individuals, so born, will have a partial similarity in the leading features of their fate. Whether their assertion is *uniformly* borne out, I will not take upon me to determine, but it would be unfair not to subjoin the following fact:—

In the newspapers of the month of February, 1820, the death of a Mr. Samuel Hemmings is noticed: it was stated that he had been an ironmonger, and prosperous in trade; that he was born on the 4th of June, 1738, at nearly the same moment as his late Majesty, and in the same parish of St. Martin's-in-the-Fields; that he went into business for himself in October, 1760; that he married on the 8th September, 1761; and finally, after other events of his life had resembled those which happened to the late King, that he died on Saturday, the 29th January, 1820.

These coincidences are, at least, highly remarkable.

[24]The Greek word for this, γοναι, though found in the Elzevir edition from which this translation is made, does not appear in other copies; the Basle edition of 1553 says merely, η τε τιμη και το αξιωμα, "*honour and rank*," which is the sense also given in the Latin translation of Perugio, 1646, without any mention of "*offspring*."

[25]In allusion to the sympathetic powers anciently attributed to certain stones.

[26]Whalley, in translating this chapter, makes the following remark on this mention of the magnet: "However much later it was that the loadstone became known in Europe, what is mentioned of it in this chapter makes it evident that it was known in Ægypt, where Ptolemy lived, in his time."—That worthy translator forgot (if indeed he ever knew) that the loadstone's property of attracting iron was known to Thales, and commented on by Plato and Aristotle, all of whom lived some centuries, more or less, before Ptolemy. It is its polarity that was not known until the 11th or 12th century; and the French say that the earliest notice of that polarity is found in a poem of Guyot of Provence, who was at the Emperor Frederick's Court at Mentz in 1181.—See the French Encyclopædia, &c.

[27]Respecting the effect here asserted to be produced on the magnet by garlick, I have found the following mention in a book called "The Gardener's Labyrinth," printed at London in 1586. "Here also I thought not to ouerpasse the maruellous discord of the adamant-stone and garlike, which the Greeks name to be an Antipatheia or naturall contrarietie betweene them; for such is the hatred or contrarietie between these two bodies (lacking both hearing and feeling), that the adamant rather putteth away, than draweth to it, iron, if the same afore be rubbed with garlike; as Plutarchus hath noted, and, after him, Claudius Ptolemæus. Which matter, examined by divers learned, and founde the contrarie, caused them to judge, that those skilful men (especially Ptolemie) ment the same to be done with the Egyptian Garlike; which Dioscorides wrote to be small garlike, and the same sweete in taste, possessing a bewtifull head, tending unto a purple colour. There be which attribute the same to Ophioscoridon, which Antonius Microphonius Biturix, a singular learned man, and wel practised in sundry skilles, uttered this approoued secrete to a friend whom he loued."

In the same book, the "Ophioscoridon" is thus spoken of: "There is another wild garlike which the Greeks name Ophioscoridon; in English Ramsies; growing of the owne accord in the fallow fieldes."

Cornelius Agrippa (according to the English translation) has stated that the presence of the diamond also neutralizes the attractive power of the magnet. But as that great magician was somewhat inclined to quibbling, it is not impossible that by the word he uses for "diamond" (viz. *adamas*) he may mean the adamant or loadstone; which would reduce his assertion merely to this, that one magnet will counteract another.

[28]This seems to explain the origin of the old alliance between medicine and astrology, so universally preserved until almost within the last century.

[29]It will be recollected that the Ptolemaic hypothesis considers the Sun as a planetary orb, in consequence of his apparent progress through the zodiac.

[30]"Astronomers call the planets matutine, when, being oriental from the Sun, they are above the earth when he rises; and vespertine, when they set after him." Moxon's Mathematical Dictionary.

[31]Whalley here appends the following note: "To this chapter may be properly added, that a planet is said to be diurnal, when, in a diurnal nativity, above the earth; and, in a nocturnal nativity, under

the earth: but nocturnal, when, in a nocturnal nativity, above the earth; or, in a diurnal nativity, under the earth."

[32]Although all the positions mentioned in this paragraph are not applicable to Venus and Mercury, which can never rise at night, that is to say, at sunset, and although the author in the beginning of the chapter speaks only of the Moon and the three superior planets, there yet seems no reason why the orbits of Venus and Mercury should not be similarly divided by their inferior and superior conjunctions, and their greatest elongations.

The following is from Whalley: "The first station, in this chapter mentioned, is when a planet begins to be retrograde; and the second station when, from retrogradation, a planet becomes direct. They" (the planets) "begin to rise at night when in opposition to the Sun."

[33]The little Torch; now known by the name of Aldebaran.

[34]Castor.

[35]Pollux.

[36]Cor Leonis.

[37]Called by the ancients χηλαι, Chelæ, or the *claws* of Scorpio; which sign they made to consist of 60 degrees, omitting Libra. Thus Virgil in the first Georgic, line 33, &c.

Quo locus Erigonen inter, Chelasque sequentes
Panditur: ipse tibi jam brachia contrahit ardens
Scorpius, et cœli justâ plus parte reliquit.

Ovid, likewise, takes the following notice of Scorpio:—

Porrigit in spatium signorum membra duorum.

Met. 2, l. 198.

[38]Adams's Treatise on the Globes calls this star "Kalb al Akrab, or the Scorpion's heart," and adds, that "the word Antares (if it is not a corruption) has no signification." But it should be observed that Ptolemy states that this star partakes of the nature of Mars: it seems therefore not improbable that Antares may be a regular Greek word, compounded of αντι *pro* and αρης *Mars*, and signifying *Mars's deputy*, or *lieutenant*, or *one acting for Mars*.

[39]Salmon, in his "Horæ Mathematicæ, or Soul of Astrology" (printed by Dawks, 1679) divides each sign of the zodiac into six faces of five degrees each, "because that in every sign there are various stars of differing natures"; and he gives a particular description to each face, depending on its ascension or culmination. This seems an attempt to adapt Ptolemy's signification of the several stars, composing the different signs, to some general rule or mode of judgment: but it does not merit the implicit assent of astrologers. It is understood that Salmon was not the inventor of this division of the signs into faces, but that it came originally from the Arabian schools.

[40]Canis Minor.

[41]"Of the fixed stars in general," Whalley says, "Those of the greatest magnitude are the most efficacious; and those in, or near, the ecliptic, more powerful than those more remote from it. Those with north latitude and declination affect us most. Those in the zenith, influence more than others, more remote. Likewise such as are in partial conjunction with, or in the antiscions of any planets, or which rise and set, or culminate with any planet, or are beheld by any planet, have an increase of power: but of themselves the fixed stars emit no rays."

[42]This sentence shows the futility of the objection raised against astrology (and mentioned in the Preface to this translation) that the signs have changed and are changing places. It is clear from this sentence that Ptolemy ascribes to the 30 degrees after the vernal equinox, that influence which he has herein mentioned to belong to Aries; to the next 30 degrees, the influence herein said to belong to Taurus; and so of the rest of the zodiac. We should rather say that the stars have changed places, than that the parts of heaven, in which they were once situated, have done so. Ptolemy himself seems to have foreseen this groundless objection of the moderns, and has written, in the 25th chapter of this book, what ought completely to have prevented it. It has certainly been one of the misfortunes of astrology to be attacked by people entirely ignorant of its principles.

[43]In other words, the Sun then begins to diminish his declination, which, at the first points of the said signs, is at its greatest amount.

[44]Whalley, in his note upon this chapter, seems to have been surprised that no mention is made here by Ptolemy of the *conjunction*; but he overlooked the fact that the chapter treats only of parts of the zodiac configurated *with each other*; and that it was not possible for Ptolemy to conceive how any part could be configurated *with itself*. It is, therefore, by no means wonderful that the

conjunction is not inserted here along with the rest of the aspects; although it is frequently adverted to in subsequent chapters, and its efficacy particularly described.

[45]From the tenor of this chapter it was formerly doubted whether the author intended to admit in his theory only zodiacal aspects, and to reject those which are called mundane; but Placidus has referred to the 4th Chapter of the 8th Book of the Almagest (which will be found in the Appendix to this translation) to prove that Ptolemy distinctly taught two kinds of aspect; one in the zodiac and one in the world. Whalley quotes the opinion of Placidus, which he says is farther confirmed by the 12th Chapter of the 3rd Book of this very treatise, where it is stated that the ascendant and the eleventh house are in sextile to each other; the ascendant and the mid-heaven in quartile; the ascendant and the ninth house in trine; and the ascendant and the occidental angle in opposition; all which certainly seems to be applicable to mundane aspects in particular.

[46]Whalley has a very lengthy note upon this and the preceding chapter, to show that Ptolemy here speaks of zodiacal parallels, or parallels of declination, and to point out the necessity of observing a planet's latitude, in order to ascertain its true parallels. It is, however, to be recollected, that the parallels now alluded to are distinct from the *mundane parallels*, which are equal distances from the horizon or meridian, and are considered by Ptolemy in the 14th and 15th Chapters of the 3rd Book of this work; although not under the express name of mundane parallels.

[47]It has never been very clearly shown how the followers of Ptolemy have reconciled the new aspects (called the semiquadrate, quintile, sesquiquadrate, biquintile, &c.) with the *veto* pronounced in this chapter. Kepler is said to have invented them, and they have been universally adopted; even Placidus, who has applied Ptolemy's doctrine to practice better than any other writer, has availed himself of them,† and, if the nativities published by him are to be credited, he has fully established their importance.

Salmon, in his "Horæ Mathematicæ," before-mentioned, gives a long dissertation (from p. 403 to p. 414) on the old Ptolemaic aspects, illustrative of their foundation in nature and in mathematics; and, although his conclusions are not quite satisfactorily drawn, some of his arguments would seem appropriate, if he had but handled them more fully and expertly; particularly where he says that the aspects are derived "from the aliquot parts of a circle, wherein observe that, although the zodiac may have many more aliquot parts than these four (the sextile, quartile, trine, and opposition), yet those other aliquot parts of the circle, or 360 degrees, will not

make an aliquot division of the signs also, which in this design was sought to answer, as well in the number 12, as in the number 360." The passage in which he endeavours to show that they are authorized by their projection, also deserves attention.

All Salmon's arguments, however, in support of the old Ptolemaic aspects, militate against the new Keplerian ones; and so does the following extract from the "Astrological Discourse" of Sir Christopher Heydon: "For thus, amongst all ordinate planes that may be inscribed, there are two whose sides, joined together, have pre-eminence to take up a semicircle, but only the hexagon, quadrate, and equilateral triangle, answering to the sextile, quartile, and trine irradiated. The subtense, therefore, of a sextile aspect consisteth of two signs, which, joined to the subtense of a trine, composed of four, being regular and equilateral, take up six signs, which is a complete semicircle. In like manner, the sides of a quadrate inscribed, subtending three signs, twice reckoned, do occupy likewise the mediety of a circle. And what those figures are before said to perform" (that is, to take up a semicircle) "either doubled or joined together, may also be truly ascribed unto the opposite aspect by itself; for that the diametral line, which passeth from the place of conjunction to the opposite point, divideth a circle into two equal parts: the like whereof cannot be found in any other inscripts; for example, the *side of a regular pentagon*" (the quintile) "*subtendeth 72 degrees, of an octagon*" (the semiquadrate) "*but 45; the remainders of which arcs, viz. 108 and 135 degrees, are not subtended by the sides of any ordinate figure*."

† Except the semiquadrate, which he has not at all noticed.

[48]Saturn being also malefic in his nature.

[49]The planets, having two houses, are said to be more powerful in one by day and in the other by night: thus,

Saturn's	day house is	Aquarius,	his night house	Capricorn
Jupiter's		Sagittarius		Pisces
Mars's		Aries		Scorpio
Venus's		Taurus		Libra
Mercury's		Gemini		Virgo

The above is from Whalley; but the same disposition is to be found in all modern astrological writers.

[50]The “lunar condition” here spoken of refers to the position of Aries (Mars’s house) in the lunar semicircle.

[51]Capricorn being in the solar semicircle.

[52]The reason for making Saturn diurnal lord of this triplicity may be found in Chap. vii.

[53]This familiarity seems to arise from the sextile aspect between Aquarius, the diurnal house of Saturn, and Sagittarius, the diurnal house of Jupiter.

[54]In reference to the terms of the planets, Placidus has these words (according to Cooper’s translation): “The dignity of the planets in the signs and their parts, which are called the bounds and terminations” (*quasi*, terms), “have a real and natural foundation; to wit, the powerful aspect or proportional influxes to the movable points in which the stars begin to produce the primary qualities. So that, according to those things we have explained in the philosophy of the heavens, these are found to agree so well with the Ægyptian boundaries” (terms), “that they are highly deserving of admiration.”

[55]This total is the 360 degrees of the zodiac, requiring to be divided according to correspondent portions of the equator; by which all time is reckoned.

[56]The degrees here mentioned are degrees of the equator.

[57]See, in the Appendix, an extract from these tables; the whole of which are to be found in the Almagest.

[58]The cause of this disposition is that Cancer, the house of the Moon, partakes of moisture, and counteracts Mars’s dryness; while Leo, the Sun’s house, is hot, and counteracts Saturn’s cold.—Vide Chap. iv, and conclusion of Chap. vii of this book.

It may further be observed, that Jupiter’s right, by triplicity, to the first degrees in Leo, is of course surrendered to Saturn, on the principle that the malefics have greater potency in the houses of the luminaries.

[59]*Vide* Chapters xii and xiv of this Book.

[60]*Vide* Chapter xx. It of course follows that Saturn is in his proper face when he is five signs, or in quintile, after the Sun or before the Moon; that Jupiter is so when in trine; Mars when in quartile;

Venus when in sextile; and Mercury when only one sign (or in modern phrase, in semi-sextile), after the Sun or before the Moon.

[61]This has been understood to mean, when the planets or luminaries are within each other's orbs; Saturn's orb being 10 degrees, Jupiter's 12, Mars's 7 degrees 30 minutes, the Sun's 17 degrees, Venus's 8, Mercury's 7 degrees 30 minutes, and the Moon's 12 degrees 30 minutes.

[62]Astrologers generally agree, that the inferior planets always apply to the superior, but the superior never to the inferior, except when the inferior be retrograde. In the present instance it seems most probable that the author means the planet which is more occidental, by "the planet which precedes." He often uses "precedent" as equivalent to "occidental" in regard to the daily revolution of the heavens: and thus a planet in the first degree of Aries would precede, and be more occidental than one in the sixth degree of Aries, to which latter it would, by the regular planetary motion, be applying.

[63]On this, Whalley says that "the less the difference of latitude of the planets in conjunction, the more powerful will be the influence: for if two planets in conjunction have each considerable latitude of different denomination, the influence of such conjunction will be much lessened."

[64]Τουτ εσι επι το κεντρον της γης. The precise meaning of the word κεντρον is "centre," rather than "angle"; but Ptolemy uses it throughout this work, in speaking of the four angles of heaven, and I conceive he uses it here to signify an angle at, or on, the earth. The following definition of an aspect, by Kepler, strengthens my opinion: "An aspect is an angle formed on the earth, by the luminous rays of two planets; efficacious in stimulating sublunary nature."

[65]Placidus (Cooper's translation) says that "the three superiors are supposed to be stronger, if they are found to be matutine, or eastern, from the Sun; the three inferiors, vespertine, or western; for then they have a greater degree of light, in which consists their virtual influence, and then they are called oriental; but occidental if otherwise. Every one knows how largely, yet to no purpose, authors have treated of the orientality of the planets."

Moxon's Mathematical Dictionary has the following words on the same subject: "Now the three superior planets are strongest, being oriental and matutine; but the three inferior when they are occidental and vespertine. The reason is, because the first in the first case, but the last in the second, do then descend to the lowest part of their orbit, are increased in light, and approaching

nearer the earth; and so on the contrary, the inferiors matutine, the superiors vespertine are weakened."

[66]In a note on the 6th Chapter of this Book, Whalley says that, "according to Ptolemy, such as are between the ascendant and mid-heaven obtain the first place of strength, and are said to be in their oriental orientality: but, between the western horizon and the lower heaven, in their occidental orientality, which is the second place of strength: between the lower heaven and the ascendant, in their oriental occidentality, the first degree of weakness; and between the mid-heaven and western horizon, in their occidental occidentality, the weakest place of all." This is all very pretty jargon, but certainly NOT "according to Ptolemy," who distinctly says, on the contrary, that if a planet "is on the actual horizon, or succedent to the horizon, it is also *powerful, and particularly* if in the eastern quarter." The last member of this sentence, as well as the conclusion of this 27th Chapter, shows that Ptolemy did not consider a situation between the mid-heaven and western horizon to be "the weakest place of all."

[67]*Vide* Chap. iii, Book I, pp. 13-14.

[68]"Under the Bears," in the Greek.

[69]Or, perhaps, Bastarnia, a part of the ancient European Sarmatia.

[70]This should probably be understood to mean in a mundane point of view, agreeably to Chaps. VI and XV, Book I. For when Aries is on the ascendant, it is, of course, oriental and masculine; and Sagittarius must consequently then be in the eighth house, occidental, and therefore feminine.

[71]The customs of nations have, in some degree, altered since Ptolemy made this severe charge against us and our brethren in the north and west of Europe. The following passage also occurs in this part of the original text:—Προς δε τας συνουσιας των αρσενικων ανακινουμενοι και ζηλουντες, και μητε αισχρον μητε αναλδρον τουτο νομιζοντες. δια τουτο ουδε εκλυονται, οτι ουδε ως πασχοντες διακεινται επι τοντω, αλλα φυλαττουσι τας ψυχας ανδρειους.

[72]The Greek is as follows: και τα μορια αυτων τα γεννητικα ανατιθεασι τοις θεοις· διοτι ο σχηματισμος των ειρημενων αςερων φυσει σπερματικος εσιν· Follies, similar in their kind to these, are still practised by the Faquirs of Hindostan, and by other religious sects in Asia.

[73]Φανερως ποιουμενοι τας προς τας γυναικας συνουσιας·

[74]The author gives a singular reason for this incest: μισουσι δε τας (συνουσιας) προς τους αρσενας. δια τουτο και οι πλειοι αυτων εκ των μητερων τεκνοποιουσι·

[75]The epithet is remarkable, not only as being, in the opinion of a Gentile, merited by the Jews, among other nations, but also at a period scarcely exceeding a century after their most heinous crime had been committed, expressly under the cloak of religion. It seems, however, that the Jews were charged with atheism by other writers also, and on account of their neglect of the false gods of the heathens; viz. "*falsorium deorum neglectus*: quam candem causam etiam Judæis maledicendi Tacitus habuit, et Plinius Major, cui Judæi dicuntur *gens contumeliâ numinum insignis*." See Clark's Notes on Grotius de Verit. Relig. Christ. Lib. 2, §2.

[76]Other editions say "Saturn."

[77]It is usually understood that the male deity, coupled by the Phrygians with Cybele, "the mother of the Gods," was called by them Atys; and that Adonis was the name used by the Phœnicians in addressing the associate of Venus. It has been said that these divinities were identical with the Isis and Osiris of the Ægyptians.

[78]The name of Africa was, in Ptolemy's time, limited to those parts of the coast on the Mediterranean which contained the ancient Utica, and in which Tunis now stands. Josephus says the name is derived from Afer (one of the posterity of Abraham by Cethurah), who is stated to have led an army into Libya, and to have established himself in the country. This Afer is, of course, the same with Epher, mentioned in the fourth verse of the 25th chapter of Genesis, as a son of Midian, one of the sons of Abraham by his concubine Keturah.

[79]It does not appear why this practice should have been remarked as a national peculiarity, unless in distinction from the custom of burning the dead among the Greeks and Romans. Interment is recorded as having been usual among the Jews, and it is known to have been common among many ancient barbarous nations.

A conjecture may perhaps be allowed, that the author, when he wrote this passage, had in his mind the magnificent subterranean palaces, constructed for the dead, in parts of the region in question; some of which have been recently made known to the modern world by the sagacity and enterprise of the celebrated Belzoni.

[80]Τινες δε και καταφρονουσι των γεννητικων μελων.—The "contempt" here expressed by καταφρονουσι has been taken by all translators (except Whalley) to signify "mutilation."

[81]History warrants the high enconium here given to the natives of these countries. Ægypt was the acknowledged mother of the arts and sciences, and at one time the great depot of all the learning of the world: her school of astronomy (a science which our author may be supposed to have placed in the first rank), founded at Alexandria by Ptol. Philadelphus, maintained its superior reputation for a thousand years. Cyrenaica gave birth to many illustrious philosophers, and, among them, to Eratosthenes, who is said to have invented the armillary sphere. This great man measured the obliquity of the ecliptic, and, though he erroneously reckoned it at only 20½ degrees, it should be recollected that he lived 200 years before the Christian æra. He also measured a degree of the meridian, and determined the extent of the earth, by means similar to those adopted by the moderns.

[82]Whalley remarks on this passage, that the gradual progress of the fixed stars "from one sign to another, is in an especial manner to be regarded in considering the mutations, manners, customs, laws, government, and fortune of a kingdom."

[83]As shown in the Table at page 51.

[84]It does not appear that the text here warrants the conclusion which Whalley has drawn from it, viz. "that wherever eclipses are not visible, they have no influence, and therefore subterranean eclipses cannot have any." Ptolemy declares, that *all* countries in familiarity with the ecliptical place will be comprehended in the event; and, with regard to the visibility or invisibility of the eclipse, he says merely that its effects will be *principally* felt in such of the said countries as might have obtained a view of the eclipse.

[85]Temporal or solar hours are duodecimal parts of the Sun's diurnal or nocturnal arc, and are numbered by day from sunrise to sunset; by night, from sunset to sunrise.

[86]Equatorial hours are the twenty-four hours of the earth's revolution on its axis. Each of them is equal in duration to the passage of 15 degrees of the Equator; and they are numbered from noon to noon. A particular explanation of the astronomical use, both of temporal and equatorial hours, is to be found in the 9th Chapter of the second Book of the Almagest; an extract from which is given in the Appendix.

[87]The three periods of four months each, stated in this paragraph, are applicable to solar eclipses only; for lunar eclipses, these periods may be reckoned at ten days each; that number of days bearing the same proportion to a month, as four months to a year. On this point, Whalley, with his usual inaccuracy, has asserted, that "in eclipses of the Moon, two days, or thereabouts, are equal to the four months" here reckoned in eclipses of the Sun. He adds, however, what perhaps may be true, that "lunar eclipses are by no means so powerful as those of the Sun, although more so than any other lunation."

[88]That is to say, from any combinations of the Sun and Moon which may take place after the date of the eclipse, but before the close of its effect.

[89]The edition of Allatius does not contain the words here marked by inverted commas; but they are found in other editions of the text, and seem necessary to complete the sense of the passage.

[90]"When planets, in election for Lords of the eclipse, are found of equal strength and dignity, those which are direct are to be preferred before those which are retrograde; and the oriental before the occidental."—*Whalley's "Annotations."*

[91]That is to say, in the Almagest, Book VIII, Chap. IV; which chapter is given, entire, in the Appendix.

[92]"In electing fixed stars, Cardan directs to observe the angle which the eclipse follows, and that which it precedes: as, if the eclipse be between the seventh house" (or occidental angle) "and the mid-heaven, the stars which are in the seventh shall be preferred; and next, those in the mid-heaven; but, if between the mid-heaven and the ascendant, those in the mid-heaven shall have the preference; and next, those in the ascendant."—*Whalley's "Annotations."*

[93]It is perhaps unnecessary to remark, that, in speaking of ruling places, as liable to be situated in Aquila, Delphinus or Argo, Ptolemy alludes only to the places of the fixed stars in dominion: since the ecliptical place and the planets must be confined to the zodiacal signs.

[94]According to Whalley, Cardan, in reference to the nine modes of configuration, applicable to the fixed stars, says, "When a fixed star is with any planet, or in any angle, consider whether it be by any of these ways; if not, it is most weak; if it be, consider whether it be with the Sun, and not to be seen; then it is very weak. Or if it is to be seen, and is with the Sun occidental, it is indifferent.

Or if it be seen, and is not with the Sun, it is stronger; or if it be seen, and is oriental, then it is strongest."

[95]That is to say (technically speaking), by reception, or by being posited in a sign in which another planet has a certain dignity or prerogative.

[96]In conformity to the rule laid down in Chap. VI of this Book, those individuals whose nativities may thus resemble the position of the heavens at the time of an eclipse, and who are here stated to be chiefly liable to the effects of the eclipse, will be more affected by it, if it should be visible to them.

To the precepts contained in this chapter, Placidus makes the following allusion in his remarks on the nativity of Cardinal Pancirole. "Any significator whatever, together with the other stars, whilst they are moved by a converse universal motion, change the aspect alternately, and consequently the mundane rays, as it likewise happens when they acquire parallels: the rays thus acquired are of a long continuance, and denote a certain universal disposition of the things signified, either good or bad, according to the nature of the aspecting stars; as it happened to this Cardinal, who some years before his death was always sickly: and this observation is wonderful in the changes of the times and weather; for this principle Ptolemy adhered to in the Almagest, lib. VIII, cap. 4; and this doctrine he also mentions in the 2nd Book of Judgments, in the chapter on the Nature of Events."—(Cooper's Translation, p. 272.)

[97]When a comet appears out of the zodiac, a line should be drawn from one zodiacal pole to the other, through the spot where it appears; and that spot is to be considered as being in familiarity with the same countries as those parts of the zodiac which may be on the same line.—*Vide* Chap. IV of this Book, relative to the manner in which fixed stars out of the zodiac hold familiarity with certain regions and countries.

[98]The Neomenia, or new Moon, was observed as a festival with much solemnity in earlier ages and by the most ancient nations. It was celebrated by the Israelites, as well as by Pagan; and it may perhaps be gathered from the 5th and 6th verses of the 20th Chapter of the 1st Book of Samuel, that it was kept once in a year with greater ceremony than at other times: this was done, probably, at the "New Moon of the Year," as Ptolemy calls it; or, in other words, at the new Moon nearest to the vernal equinox.

[99]That is to say, at the new and full Moon taking place during the Sun's progress through each sign.

[100]The passage marked thus " " is not in the Greek, but is found in two Latin translations.

[101]According to Wing, in his "Instructions to the Ephemerides," printed in 1652, the signs, as mentioned in this chapter by Ptolemy, are to be considered in their quality as constellations, and not as spaces of the heavens. This opinion, however, seems to me to be erroneous; for Ptolemy has already devoted a chapter in the 1st Book to the detail of the influences of the several stars in the respective constellations of the zodiac; and he moreover speaks, in the present chapter, of the operation of Aries, as owing to the presence of the Equinox. This he could not have done, had he spoken of the signs as constellations instead of spaces.

[102]The temperaments here alluded to are, probably, heat and cold.

[103]"*Before*." Although I have thus Englished the word, προ, I think it properly requires to be here rendered, by "*at*" or "*near to*" rather than "*before*." Firstly, because my author (in speaking of the commencement of each quarter of the year, in the 11th Chapter, p. 93), has expressly stated that "the spring is to be dated from the new or full Moon taking place when the Sun is *nearest* (εγγιζα) to the first point of Aries; the summer from that, when he is *nearest* the first point of Cancer," &c., &c.; and (in p. 94) he states that certain general effects are brought about by the new or full Moon occurring *at* (κατα) the aforesaid points. Secondly, because, in a few lines further on, in speaking of the monthly consideration, p. 98, he again uses only εγγιζα, in reference to the present passage, in which, however, he has used only προ. Thirdly, it is a proper inference that he meant to point out here the new or full Moon which may happen *nearest* to the tropical or equinoctial points, because he has previously and explicitly taught that the principal variation of all things depends upon those points. Lastly, Allatius has here rendered the word by no other than *proximé*, which is also the word given in the Perugio Latin of 1646.

On the other hand, Whalley, in his note on the present chapter, says, that "according to this Prince of Astrologers" (meaning Ptolemy), "we are to observe the new or full Moon preceding the ingress, only, for our judgment on the succeeding quarter, and not the lunation succeeding: and the reason I conceive to be, because the lunation, which immediately precedes the ingress, carries its influence to the very position of the ingress itself, but not so that which follows the ingress." Wing, in his Introduction to the Ephemerides (London, 1652) also says, that "for the knowledge of the

weather, it is requisite to observe the conjunction or opposition of the luminaries next *preceding* the Sun's ingress into the first point of Aries."

Now, if a new or full Moon happen *immediately after* the Sun's transit or ingress, the previous full or new Moon must have happened *a fortnight before* the said transit or ingress; and, after considering the other parts of Ptolemy's doctrine, I do not conceive, that he intended to teach, in this chapter, that a *previous* lunation, when at so great a distance before the important ingress, would have a greater influence over the ensuing quarter of the year, than a *subsequent* lunation taking place so closely after the said ingress.

[104]"*Both the places.*" These are the places of the new or full Moon, and of the following angle; as before mentioned with regard to the quarterly consideration.

[105]Similar precepts may be found finely illustrated in Virgil's 1st Georgic, *vide* I, 433 *et infra*:

"Sol quoque et exoriens et cum se condit in undas
Signa dabit:"——

[106]Virgil has said almost the same thing in these beautiful lines:

"At si virgineum suffuderit ore ruborem
Ventus erit: vento semper rubet aurea Phœbe."—*Georg.* I, l. 430.

See also the whole passage, beginning at l. 424:

"Si vero Solem ad rapidum Lunasque sequentes
Ordine respicies," &c.

[107]At this place, the following sentence, not found in the Greek, is inserted in a Latin translation:

"If the northern of the two stars, situated one on each side of the Præsepe, and called the Asini, should not appear, the north wind will blow: but, if the southern one be invisible, the south wind."

[108]These coruscations are, perhaps, similar to those now known by the name of the Aurora Borealis.

[109]Virgil again:

"Sæpe etiam stellas vento impendente videbis
Præcipites cœlo labi."—&c. *Georg.* I, l. 365.

Zaid n. adwan

A great part of the 1st Georgic consists of astrological rules for predicting the weather, closely resembling the precepts here given by Ptolemy. Virgil is said to have adopted his doctrine from Aratus.

[110]The Division of Time is subsequently laid down by the author, in the last Chapter of the fourth Book.

[111]The words, thus marked " ", are not in the Greek, but in two Latin translations.

[112]It is, perhaps, needless to remark that modern improvements in science have superseded the use of this and other ancient instruments here mentioned.

[113]Although the "clepsydra," or water-clock, was commonly used among the ancients for various purposes, it appears, from Martian (a Latin writer, who lived about A. D. 490), that there was also a clepsydra in special use as an astrological engine.

[114]"*The Doctrine of Ascensions*," in allusion to the method of calculating the actual position of the ecliptic.

[115]"*Phase or configuration.*" Or, holding some authorized aspect to the degree in question.

[116]Or, on the ascendant.

[117]The precepts delivered in this Chapter have obtained the name of Ptolemy's Animodar: the term is probably Arabic, if it be not a corruption of the Latin words *animum*, or *animam*, *dare*, "giving animation or life"; yet this meaning seems scarcely close enough.

[118]In House, Triplicity, Exaltation, Term or Face.

[119]Δορυφορια· This word has been heretofore rendered "*satellitium*" and "satellites," but, as these terms do not seem sufficiently precise in their meaning, and are already in use to signify the minor orbs which revolve round a principal planet, I have ventured to anglicize the Greek word; the usual signification of which is a "bodyguard."

[120]Or, in other words, "should the stars, which attend the Sun, be such as rise *before him*; and those, which attend the Moon, such as rise *after* her."

[121]As described in Chap. XXVI, Book I.

[122]Saturn being applicable to the father, and Venus to the mother.

[123]The Perugio Latin translation, of 1646, inserts here, “and provided Saturn and the Sun are not impeded by being posited in unfortunate or unsuitable places.”

[124]“*Elevated.*” Moxon’s Mathematical Dictionary gives the following definition of this astrological term. “*Elevated.* A certain pre-eminence of one planet above another; or, a concurrence of two to a certain act, wherein one being stronger, is carried above the weaker, and does alter and depress its nature and influence: But wherein this being *elevated* consists, there are several opinions; some say when a planet is nearest the zenith, or meridian; others will have it only that planet is highest; or nearest to the Apogæon of his eccentric or epicycle. And Argol admits of all these, and several other advantages, and thence advises to collect the several testimonies, and that that planet, who has most, shall be said to be elevated above the other.” According to Whalley, Cardan’s opinion was that “that planet is most elevated which is more occidental and ponderous.” For myself, I conceive this opinion to be inaccurate, because, if Ptolemy meant to signify only the greater occidentality of the planet, he would (as in other instances) have used the word “*preceding*” instead of “*elevated above*”; and I incline to think, that *greater proximity to the zenith* is the truer, as well as more simple, meaning of the term “elevated.”

[125]By the quartile or opposition, as before mentioned.

[126]On this passage, Whalley remarks that “Ptolemy teacheth, from the child’s nativity, to erect schemes for the father and mother, and thence to give judgment, as if it were their proper nativities; the rule is this: If the nativity be diurnal, for the father, observe the degree the Sun is in, in the child’s nativity; and make that the degree ascending for the father; and conformable to that, order the cusps of all the other houses. If for the mother, use Venus. But if the nativity be nocturnal, for the father, take the place of Saturn; and for the mother, that of the Moon.” Whalley adds, that what in this chapter hath relation to the parents, is what shall happen to them *after* the nativity, and not *before*.

[127]Or, at the actual time of nativity.

[128]In spite of this declaration of the author, it seems, by Whalley’s note on this chapter, that Cardan maintained that the particular circumstances, liable to affect the brothers and sisters, might be inferred by adopting, as an ascendant, the degree of the planet holding chief dominion over the place of brethren, and erecting a scheme thereby; in a mode similar to that allowed by Ptolemy in the case of the parents.

[129]That is to say, from the angles in quartile (and therefore hostile also) to the mid-heaven.

[130]The text does not show whether it be necessary that Saturn and Mars should *both* be in the ascendant, in order to produce the effect described; nor whether the same effect would not follow, if one of them should be in the ascendant, and the other in the occidental angle, or even in some other position.

[131]*Vide* Chapter VI, Book I.

[132]The planet here alluded to, seems to be that which may be connected with most of the ruling places.

[133]I have looked in many other books for this word "*Anactores*" (plural of ανακτωρ), as designating three particular individuals born at the same birth; for which signification it is here used by Ptolemy; but my search has been in vain. Cicero has, however, written a passage, in which a word, very nearly resembling it, occurs, and which would seem to relate to the very persons alluded to by Ptolemy: viz. "The godship of the Dioscuri was established in various modes among the Greeks, and applied to various persons. One set consisted of three persons, who were styled at Athens the *Anactes*, and were the sons of Jupiter, the most ancient king, and Proserpine; their several names were Tritopatreus, Eubuleus and Dionysius." *De Nat. Deor.*, lib. 3, cap. 21.

[134]This is the second set of the Dioscuri, as stated by Cicero: they were the children of the third, or Cretan Jupiter (the son of Saturn) and Leda; their names were Castor, Pollux, and Helena. Helena, however, is not mentioned by Cicero.

[135]Core is a name of Proserpine; Liber, of Bacchus. And, although the mention here made of Ceres, Proserpine and Bacchus, as being the offspring of one and the same birth, does not accord with the usual notion of the genealogy of these divinities, it seems that Ptolemy did not so represent them without some reason. For, in cap. 24, lib. 2, *De Nat. Deor.*, Cicero speaks of Liber as having been deified conjointly with Ceres and Libera (another name of Proserpine); and adds, that "it may be understood, from the rites and mysteries of the worship, how the deification took place." It appears also, by Davies's notes on Cicero, that Livy and Tacitus both speak of the copartnership in divinity exercised by Liber, Libera and Ceres. There is not, however, any occasion at present to dive deeper into the question of the generation of these deities; for our author has advertised to

zaidn.aowan

them only to point out that so many males or females will be produced at one birth, under certain configurations of the stars.

[136]Whalley says here, “chiefly the ascendant and mid-heaven.”

[137]Whichever might have been nearer in time.

[138]It is perhaps superfluous to mention that the two kinds of animals here named (as well as many others) were venerated by the Ægyptians.

[139]The Greek says “enigmatical.”

[140]One Latin translation has rendered this word “stammerers”; and, as Harpocrates was the god of silence, Ptolemy has probably used the epithet to signify defect of speech.

[141]“Dumb.” The Greek is οδοντων εξερημενον, “*deprived of teeth*,” and Allatius has so translated it: but other translations render these words by *dumb*, which, considering the nature of Mercury, seems their preferable signification.

[142]A prorogator is either a luminary, planet, or a certain degree of the zodiac, which determines the duration of life, or the time of the accomplishment of any event: it is hereafter fully treated of in the 13th Chapter of this Book; which shows that, in the instance now mentioned, it would be a luminary, either in the ascendant, or in the mid-heaven.

[143]The epithet *anæretic* is a term of art, adopted from the Greek, signifying fatal, or destructive.

[144]The Latin translation, printed at Perugio in 1646, has here the following passage in addition: “But it must be seen which luminary may follow the other in the succession of the signs; for if the Moon should so follow the Sun, the part of Fortune is also to be numbered from the horoscope or ascendant, *according* to the succession of the signs. But if the Moon precede the Sun, the part of Fortune must be numbered from the ascendant, *contrary* to the succession of the signs.”

There is a long dissertation on the part of Fortune, in Cooper’s Placidus, from pp. 308 to 318; and, among the directions there given for computing its situation, the following seem the most accurate and simple: viz. “In the diurnal geniture, the Sun’s true distance from the east is to be added to the Moon’s right ascension, and in the nocturnal, subtracted; for the number thence arising will be the place and right ascension of the part of Fortune: and it always has the same declination with the Moon, both in number and name, wherever it is found. Again, let the Sun’s oblique

ascension, taken in the ascendant, be subtracted always from the oblique ascendant of the ascendant, as well in the day as in the night, and the remaining difference be added to the Moon's right ascension; the sum will be the right ascension of the part of Fortune, which will have the Moon's declination." It is shown also by this dissertation, that the situation of the part of Fortune must be necessarily confined to the lunar parallels; that it can but rarely be in the ecliptic; and that its latitude is ever varying. Cooper also adds, from Cardan's Commentaries on the Tetrabiblos, that "if the Moon is going from the conjunction to the opposition of the Sun, then the Moon follows the Sun, and the part of Fortune is always under the Earth, from the ascendant; but if the Moon has passed the opposition, she goes before the Sun, and the part of Fortune is before the ascendant, and always above the earth." This remark of Cardan's is, in effect, exactly equivalent to what is stated in the additional passage inserted in the Perugio Latin translation, and given above.

In the Primum Mobile of Placidus (Cooper's translation, p. 45), the following remark and example are given: "The part of Fortune is placed according to the Moon's distance from the Sun; and you must observe what rays the Moon has to the Sun, for the latter ought to have the same, and with the same excess or deficiency, as the part of Fortune to the horoscope. As the Moon is to the Sun, so is the part of Fortune to the horoscope; and as the Sun is to the horoscope, so is the Moon to the part of Fortune. So, in the nativity of Charles V, the Moon applies to the ultimate sextile of the Sun, but with a deficiency of 7° 45′: I subtract the 7° 45′ from 5° 34′ of Scorpio, the ultimate sextile to the horoscope, and the part of Fortune is placed in 28° 9′ of Libra." N.B.—In this nativity, according to Placidus, the Sun is in the second house, in 14° 30′ of Pisces: the Moon in the ascendant, in 6° 45′ of Capricorn; the ascendant is 5° 34′ of Capricorn; and the part Fortune is in the ninth house, in 28° 9′ of Libra.

[145]According to her position in the scheme of the nativity.

[146]Placidus, in remarking on the nativity of John di Colonna, after stating his opinion that it is an error to suppose that a malign influence to the horoscope, when the horoscope has *not* the primary signification of life is anæretic, says, that "the order and method which Ptolemy lays down for the election of a prorogator are quite absurd, unless life be at the disposal of a sole prime significator only." He proves by other arguments also, and by instances of the fact, that "*one only* signifies life, elected according to Ptolemy's method." (Cooper's translation, p. 184.)

Zain n. adwan

[147]"*Horary proportion.*" So the Perugio Latin of 1646; the Greek word, however, is ωριμαιαν, which seems to be compounded of ωρα and ιμαω; and, if so, the literal signification would be "extraction of hours."

[148]By the apparent motion of the planetary system. On this passage, Placidus has the following observations: "In directing the significator to the west, you must consider what stars or mundane rays are intercepted between the significator and the west; if fortunate, add their arc to the significator's arc of direction to the west; if unfortunate, subtract it from the same, and it will give the arc of direction, augmented or diminished according to Ptolemy. How largely and differently authors have spoken of this direction of the significator to the west, putting various constructions on the words of Ptolemy, is known to every one. See Cardan in his Commentaries, Maginus in Prim. Mob. and the Use of Legal Astrology in Physic, c. viii, where he delivers the sentiments of Naibod. Argol censures wholly this doctrine of Ptolemy's, of directing the moderator of life to the west, as vain and useless; but I say it is worthy of remark, and altogether comformable to truth; because then the rays and intermediate stars of the malign only lessen the arc of direction to the west, and do not destroy life, when, by a right direction, the moderator or life does not remain at the same time with the malignant planet: for, should this happen, they kill, without any manner of doubt." (Cooper's translation, pp. 106 and 108.)

[149]"*Horary times.*" These are the number of equatorial degrees which any degree of the zodiac may appear, in a certain latitude on the earth, to transit in an equatorial hour.

[150]By the apparent motion of the planetary system.

[151]In reference to this passage, Placidus, in speaking of the death of Octavian Vestrius of Rome, has these words: "the Moon is found in a parallel declination of Mars, and Saturn with the opposition of Mars; the sextile of Jupiter to the Sun could give no assistance, because Jupiter is cadent, and the ray sextile is very weak, especially when it is the principal ray: for which reason, Ptolemy, in the chapter of Life, when he mentions the planets that are able to save in the courses of the infortunes, does not name the sextile, but the quartile, trine, and opposition; because the sextile ray is feeble, particularly when it is less than 60°: neither could Venus assist, as she was cadent from the house, and in a sign inimical to the Sun," &c. (Cooper's Translation, p. 286.)

[152]Literally, and perhaps more properly, "its meeter."

[153]That is to say, orbs, in contradistinction to prorogations made by aspects or degrees merely.

[154]Of the stars and places brought into configuration.

[155]Whalley's translation of this passage is in direct contradiction to the sense: and even that of Allatius, as well as other Latin ones, are (if strictly correct) confused in their meaning.

[156]"*Ascensional times.*" These are, in other words, the number of degrees of the equator, equivalent to a certain number of zodiacal degrees, ascending in any particular latitude. They are also otherwise called the *oblique ascension* of such zodiacal degrees.

[157]"*Equatorial times*" here signify degrees of the equator, by which all time is measured.

[158]That is to say, of the preceding and of the succeeding body of degree.

[159]Which may be intercepted in the arc between them.

[160]This number is that of the oblique descensional times of the intercepted arc, or of the oblique ascensional times of the arc opposite to it. The whole of the instructions in this paragraph are fully exemplified in the following chapter.

[161]Or, times to be reckoned in another manner.

[162]On this passage, there has been founded (to use Whalley's words) "what we call Mundane Parallels, or parallels in the world. And, as zodiacal parallels are equal distances from the tropical or equinoctial circles, so mundane parallels are a like equal distance from the horizontal or meridianal points or circles. And as zodiacal parallels are measured by the zodiacal circle, so those mundane parallels are measured by the diurnal or nocturnal arcs: and just so long as the Sun or any other planet is, in proceeding from the cusp of the twelfth House to the cusp of the tenth, the same Sun or other planet will be in proceeding from the cusp of the tenth to the cusp of the eighth House. And the distance between Sun-rising and setting, is the diurnal arc which the meridian cuts in two equal parts. In directions, these mundane parallels have a twofold consideration: first, simple; secondly, according to the rapt motion of the earth, or the *primum mobile*: all which have been largely explained by the learned Monk, Placidus," &c. That Author has certainly stated, in one of his Theses, that "those seats, or parts of the circle, are to be received, in which the stars, having a different declination, effect equal temporal hours" (p. 22, Cooper's Translation), and he has fully exemplified this principle in other parts of his "Primum Mobile"; but Ptolemy here speaks

only of *one* of the *semi*circles between the horizon and meridian, without reference to any other semicircle, corresponding in distance from the horizon and mid-heaven; and all that he has said on the subject amounts only to this, that the prorogation is completed when the succeeding place arrives at the same semicircle on which the preceding place had been posited.

[163]The ascendant, mid-heaven, and western horizon; as mentioned in the preceding paragraph.

[164]*Vide* Note ², p. 95.

[165]This, in the Northern Hemisphere, would be the latitude of Alexandria (where Ptolemy flourished), or, in his own words, that of the 3rd Climate, passing through Lower Egypt, numbered 30° 22′.—*Vide* extracts from the Tables of the Almagest, inserted in the Appendix.

[166]This is the magnitude of the diurnal temporal hour of the first point of Gemini in the latitude prescribed.

[167]By right ascension, as shown by the Extract, inserted in the Appendix, from the Tables of Ascensions in the Almagest. The exact distance, however, according to that Table, is 147° 44′.

[168]Or rather, according to the Table, 102° 39′.

[169]That is to say, of the oblique ascension, which is here required to be reckoned; because the prorogatory and preceding place is in the ascendant. *Vide* p. 95, and Note ² in p. 94. And the first point of Gemini, on arriving at the ascendant, will be distant from the mid-heaven 102° 39′ by right ascension; the 13th degree of Aquarius being then in culmination in the prescribed latitude. The oblique ascensions in the latitude 30° 22′ N. are also shown in the extract referred to in the preceding note: and it thereby appears, that Aries and Taurus ascend in 45° 5′, instead of 46°.

[170]Or, rather, 57° 44′—by right ascension.—*Vide* extract above referred to.

[171]*Vide* p. 95

[172]Or on the cusp of the 7th House.

[173]Or, rather, 32° 16′—by right ascension again.—*Vide* extract as before.

[174]By right ascension. The amount according to the Table is, however, 102° 39′, as before stated.

[175]On which the 10th degree of Virgo will then be posited.

Zain adwan

[176]By oblique descension and ascension: *Vide* p.95.—The Table shows the amount to be 70° 23′.

[177]In reference to p. 95, and Note ¹ in the same page.

[178]The 18th degree of Cancer being then in culmination.

[179]Or semi-diurnal arcs, each equal to six temporal hours.

[180]The amount of the progressive difference of the times of prorogation, as here mentioned, is of course only applicable to the parallel of declination of the first point of Gemini, in the latitude before quoted. It must necessarily vary in all other parallels of declination, and also in all other latitudes.

[181]Oblique ascension.

[182]The times of oblique descension of any arc of the zodiac are equal to the times of oblique ascension of its opposite arc; as before explained.

[183]That is to say, at the time of the 1st point of Aries transiting the cusp of each angle respectively.

[184]The calculation of time may be greatly facilitated by the use of a zodiacal planisphere, said to have been invented about thirty years ago by Mr. Ranger, who died without making his invention public. The invention consists of a set of instruments perfectly adapted, as far as relates to the zodiac, for astronomical, as well as astrological, purposes; and the completeness with which it solves, in the most intelligible and expeditious manner, all the astronomical problems of the zodiac, deserves attention. Whether a similar planisphere was known in the days of Placidus, I am not aware; but it is worthy of remark that the following words occur in his "Primum Mobile," and seem almost to have been predicted of Mr. Ranger's planisphere:—"If any one would provide himself with a Ptolemaic planisphere, with the horary circles, crepuscules, the zodiac's latitude, and all other things requisite, it would be of very great service towards foreseeing the aspects." (Cooper's Translation, p. 87.) In the Appendix will be found a plate, containing diagrams drawn by the instruments in question, which, though not completely filled up, will show how easily, and, at the same time, how accurately, the measure of time in directions may be ascertained. The said diagrams have been adapted to the "exemplification" here given by Ptolemy; one of them being

laid down for the latitude of Alexandria, and the other for the latitude of southern Britain (51° 30′ N.), with similar positions of the preceding and succeeding places adverted to in the text.

[185]These meetings and descensions are technically termed “directions.”

[186]On these words Placidus has the following remark: “The revolutions may possess some virtue, but only according to the constitution of the stars to the places of the prorogators of the nativity, and their places of direction, but no farther; as Ptolemy was of opinion, and briefly expresses himself in his Chapter of Life. ‘Those who are afflicted, both in the places and conclusions of the years, by the revolution of the stars infecting the principal places, have reason to expect certain death.’” (Cooper’s Translation, p. 127.)

[187]Of the significators before mentioned.

[188]That of the ascendant, and that of the Moon.

[189]The original word is (in the accusative plural) αιγοηους, which Allatius has rendered, by “*pedibus caprinis*,” *goat-footed*, as if it were compounded of αιξ capra and πους *pes*; but the preferable derivation seems to be from αιξ and ωψ *vultus*; meaning “*goat-faced*.”

[190]From any one of the said planets.

[191]*Vide* Chap. VIII, Book I.

[192]The Greek is ποιουμενοι φασεις; literally “*making apparition*”; but the subsequent context seems to require the meaning I have adopted.

[193]The parts of the signs in which the planets are posited.

[194]For the operative qualities of the other constellations, *vide* Chapters X and XI, Book I.

[195]The sixth house.

[196]This seems to imply, if Saturn be in one of Venus’s places of dignity, and Venus in one of Saturn’s. Such a counterposition is technically termed “mutual reception.”

[197]In her extreme latitude, whether north or south.

[198]Της ιερας νοσου; literally, “the holy disease,” which authors have explained to mean epilepsy. Perhaps the disease was anciently called holy, because the patient, when possessed by the fit, seemed to be under the influence of some supernatural agency.

[199]That is to say, in the commencement of her separation from the aspect or conjunction of such stars.

[200]The Greek is μεταμελητικους, which means "penitent," or "prone to repentance," or "to subsequent regret." It is difficult to convey its precise meaning in the text.

[201]*Vide* Chapter XXVI, Book I.

[202]That of Mercury, and that of the Moon.

[203]This seems to imply, if well placed in elevation; as, in the mid-heaven, for instance, or in a conspicuous situation; and in possession of dignities.

[204]Or, persons: the Greek is φιλοσωματους.

[205]Or, persons: μισοσωματονς.

[206]Πρσς μιξιν θηλειων και αρρενων διακειμενσυς.

[207]Προς αρρενας δε κεκιννμενους και ζηλοτυπους.

[208]Παιδων διαφθορεας.

[209]That is to say, in her extreme latitude, whether south or north.

[210]Epilepsy is defined to be "a conclusive motion of the whole body, or some parts of its parts, accompanied with a loss of sense." The knowledge of this latter effect probably induced the author to rank it among diseases of the mind.

[211]Of Mercury, the Moon, and the ascendant.

[212]Εσπερινοι; perhaps, more properly, *nocturnal*; the word being used in contrast to ημερινοι, *diurnal*.

[213]That is to say, such events as are independent of the will, and not necessarily consequent on any peculiar conformation of the mind or body.

[214]*Vide* Chapter XIII of the 3rd Book.

[215]I have considered the words, γυναικειων δωρερεων, as comprising "*the dowry of wives*," as well as other "*gifts from women*."

zain.adwan

[216]That is to say, its duration will depend on the time requisite to complete the arc of direction or prorogation between the stars, operating the loss, and the places which give the wealth. And the calculation is to be made as pointed out in the 14th and 15th Chapters of the 3rd Book.

[217]It seems that there have been different opinions on this point. Placidus makes the following remark on the subject: "I do not take the dignities from the horoscope, but from the Sun and Medium Cœli, according to Ptolemy and others." (Cooper's Translation, p. 121.)

[218]The Perugio Latin, of 1646, says, "If either both luminaries, or only that one of the *chief quality*" (which Whalley defines to be the Sun by day, and the Moon by night) "be in an angle," &c.

[219]*Doryphory*. *Vide* Chapter V of the 3rd Book On the present passage, Placidus has the following words: "You are not to observe what is generally alleged by professors, respecting the satellites" (*quasi* doryphory) "of the luminaries, for dignities; viz. that the satellites are those planets which are found within 30°, on either side of the luminaries; but that a satellite is (also) any kind of aspect of the stars to the luminaries of what kind soever: which, if it be made by application, its power extends inwardly over the whole orb of light of the aspecting planet, and the more so, as the proximity is greater; but, by separation, it is not so. This doctrine may be seen in several chapters of Ptolemy; for, an aspecting star influences the significator, and disposes him to produce effects co-natural to him, by a subsequent direction. But a star of no aspect does not predispose the significator, and produces very little or no effect of its nature, by a subsequent direction; this is the true doctrine of the stars." (Cooper's Translation, pp. 124, 125.)

[220]The angle of the mid-heaven; see the first note to this Chapter.

[221]See the 4th Chapter of the 8th Book of the Almagest inserted in the Appendix.

[222]The Greek says merely "that one having the dominion," without specifying the place of dominion: the Latin printed at Perugio, is, however, "*dominum accipe medii cœli*," which is certainly the sense required by the tenor of the previous instructions. Whalley also has similarly rendered it.

[223]Among the ancients, a garland was an indispensable decoration at all public ceremonies, whether civil or religious, and at private banquets. The making of garlands was, therefore, a considerable employment.

[224]It would seem, from "garland-wearers" being placed here in connection with "prize-wrestlers" (αθληται), that the author intended to point out persons competent to obtain the victors' wreath in public exhibitions. But it appears that the word σεφανηφορος, *garland-wearer*, also signifies a person who was annually chosen by the priests to superintend religious ceremonies, an office similar to that of high priest. According to Athenæus, the Stephanephorus of Tarsos was invested with a purple tunic, edged or striped with white, and wore the laurel chaplet, which Plato, in the treatise *de Legibus*, describes as being constantly worn by these officers, although the other priests wore it only during the performance of the ceremonies.

[225]Meaning probably "if in mutual reception," which position has been before explained.

[226]Or makers of hieroglyphics—ιερογλυφοι.

[227]That is to say, the mid-heaven; as stated in the 4th Chapter of the 3rd Book, and in the commencement of the present Chapter.

[228]This mode of divination, as practised by the Greeks, is mentioned by Potter. It is likewise described by a learned Doctor of Medicine, Geo. Pictorius Vigillanus (in his Treatise "de Speciebus Magiæ Ceremonialis," printed at Strasburgh, 1531), as being used "when the fraudulent vanity of a dæmon renders things more like each other than eggs are to eggs." And, according to this writer, it is practised by exorcising water, and pouring it into a basin, wherein the vain and refractory dæmon is immersed: the said dæmon will sometimes remain at the bottom, and sometimes raise himself to the surface, sending forth a slender hissing; out of which the desired responses are to be formed.

[229]Κρασεσι των χρωματων.—These words have been rendered literally, but they seem to contain some figurative meaning, rather than a literal one. Perhaps the preferable sense of them is, "*by a mixture of views*," or "*from various pursuits being blended together*."

[230]The words marked with inverted commas are not in the Greek; they are found, however, in two Latin translations; that of Basle, 1541, and that of Perugio, 1646.

[231]In other Editions, "whether by conjunction or aspect."

[232]"*Saturn.*" Not found in the Elzevir edition, but in others.

[233]The words thus marked “ ” are not found in the Elzevir edition, but appear in the Latin one of Basle, 1541.

[234]Περι παιδας επιθυμητικους.

[235]That is to say, from the new and the full Moon.

[236]By mutual reception; according to Whalley, and also according to the Latin copy of Perugio, 1646.

[237]Meaning, probably, if the Moon in the husband’s nativity should be in the same position as the Sun in the wife’s nativity, or harmoniously configurated with that position.

[238]The exaltation of Venus being in Pisces, and that of Mars in Capricorn. *Vide* Chapters XXI and XXII, Book I.

[239]Libra being Venus’s house, and in Saturn’s triplicity; and Capricorn being Saturn’s house, and in Venus’s triplicity. *Vide* Chapters XX and XXI, Book I.

[240]*Vide* Note ¹ in p. 126.

[241]Instead of the Moon.

[242]*Vide* Note ¹ in p. 126.

[243]Of the planets before specified.

[244]These are such signs as are connected with each other in any manner similar to that before described, as connecting Capricorn with Pisces, and with Libra; or, in other words, signs common to the planets configurated.

[245]The following also occurs here: “και ει μεν ο εις τωνασερων δυτικος, ο δε ετερος ανατολικος εσι, και προς ανδρας και γυναικας εσονται διακειμενοι, ουχ’ υπερβολικως δε, ει δε αμφοτεροι οι ασερες δυτικοι ευρεθωσι, προς μονον το θηλυ εσονται καταφερεις. θηλυκων δε των ζωδιων υπαρχοντων εν οις οι ασερες, και αυτοι παοχειν ανεξονται τα του θηλυος. ει δε αμφοτεροι ανατολικοι ωσι, προς μονον το αρρεν ερμητικως εξουσι. των δε ζωδιον αρσενικων οντων, προς πασαν αρσενικην ηλικιαν.”

[246]To this the following sentence succeeds: εαν δε αρρενικως διακειμενοι ωσιν οι ασερες, και προς το ποιειυ.

Zain n. adwan

[247]The angle of the mid-heaven.

[248]The meaning, apparent from the commencement of the chapter, is this: “Should such planets be in the mid-heaven or its succedent house, or configurated with either.”

[249]Μοναδικην, single, or one at a birth.

[250]Διδυμογωνιαν, double, or two at a birth.

[251]That on the mid-heaven, and that on the eleventh house.

[252]Or, regard each other within the distance of seventeen degrees.

[253]That is to say; if the places of the Sun, &c., in one nativity be configurated with such parts of the zodiac as are occupied by the Sun, &c., in the other nativity.

[254]Of any of the four places above described.

[255]Than the rest of the places.

[256]Those of the Sun, Moon, Ascendant, and part of Fortune, as before mentioned.

[257]“—and the attachment, or disagreement, subsisting between them and their masters”;—so Allatius, and the Latin translation printed at Perugio.

[258]The twelfth house.

[259]The probable meaning is, “if not acting in concert”: but the Latin of Perugio says, “*si sint oppositi secundum longitudinem*.”

[260]There seems a misprint here in the original: δυσωδιων, “foul vapours,” instead of δυσοδων, “wildernesses.”

[261]On the places indicative of travelling.

[262]*Vide* the 14th Chapter of the 3rd Book; on the number of the modes of prorogation.

[263]That is to say, the sign and degree on the occidental horizon.

[264]See a subsequent note, p. 135, which gives an instance of the mode in which Placidus applied the power of the terms, in an anæretic direction.

[265]Δια σηψεων. Perhaps more properly, putridity or rottenness. The Perugio Latin translation renders it by “cancer.”

[266]Placidus, in treating of the nativity of Lewis, Cardinal Zachia, uses these words: “This example also teaches us what the sentiments of Ptolemy were concerning a violent death; when, in a peremptory place, both the enemies meet together, it is to be understood, that in the nativity the violence is sometimes first pre-ordained from the unfortunate position of the Apheta; at other times quite the contrary. But, because the direct direction happened to be in the terms of Mercury, the sickness was attended with a delirium and lethargy, so that you may perceive this to have been the true cause of the native’s death.” (Cooper’s Translation, pp. 198, 199.)

[267]Ειδε ανθωροσκοπησει προσοιον δηποτε των φωτων: which Allatius has translated, “if he should be in the ascendant opposed to either of the luminaries” (*si in horoscopo alteri luminum opponatur*); but the Latin copy of Basle, 1541, as well as that of Perugio, 1646, give the passage as now rendered. And it appears in a subsequent place, p. 201 (where the word ανθωροσκοπων occurs), that it can only be properly translated “*in opposition to the ascendant*.”

[268]Caput Medusæ.

[269]Ανθωροσκοπων. *Vide* note ³ in p. 135.

[270]That is to say, the lower heaven, or imum-cœli. Whalley has translated it, “*above* the earth,” instead of “*below*”; mistaking νπο for νπερ.

[271]On this chapter Whalley makes the following annotations: “One direction, how malevolent soever, rarely kills; and, in most nativities, there is required a train of malevolent directions to concur to death: where several malevolent directions concur so together, without the aid of intervenings of the benevolents, they fail not to destroy life.”

“In such trains of directions, the author here distinguisheth between the killing planet and the causer of the quality of death; for one planet doth not give both. The foremost of the malevolent train is the killing place, and shows the time of death; but the following directions, though benevolent, show the quality. If the train fall altogether, and none follow, for the quality observe those which precede, though at a distance and benevolent also; for, though the benevolent contribute to the preservation of life, yet they frequently specify the disease which is the cause of death. And with these, our author tells us, concur the configurating stars, the quality of the stars and signs, and the terms in which the lords happen. In violent deaths, the genethliacal positions of

the lights are to be observed, and how the malefics affect them, and (*how they*) are also concerned by directions in the quality or death." See also Chap. XIV, Book II.

[272]With respect to the periodical divisions of time.

[273]It will, of course, be remembered, that the Sun, in the Ptolemaic astronomy, is counted as a planetary orb.

[274]The Latin copy of Basle, 1541, says, "to marriages."

[275]"*Bodily*," or in conjunction.

[276]On this passage, Whalley remarks, "we are to observe in direction, that the star in exact ray with the prorogator shall be ruler until the prorogator meets another ray; that then the planet whose ray it is shall take the dominion, and so on. But if no planet aspect the hyleg (prorogator) exactly, that which casts its rays before the prorogator is to be taken for ruler of the time, till another planet's ray comes in by direction. And the lord of the term, in which the direction falls, must be considered as a co-partner in this dominion."

[277]*Vide* Chap. XIV, Book 3.

[278]The Greek is simply εις τα επομενα κατα ξωδιον; but the context proves that the entire meaning must be as now given, although the Latin translation of Perugio renders it "one year to each degree." Whalley explains that by annual periods "the author intends profections: for the taking of which, for every year from the birth, add one sign to the sign in which the aphetics are at birth, and the sign which ends at the year desired is the sign profectional for that year, and the lord of that sign is chronocrator (arbitor) for that year; so far as the degrees of that sign reach." For example, if a prorogator at birth be in 15° of Gemini, to 15° of Cancer serves the first year; but the first six months are ruled by Mercury, and the last six by the Moon and Jupiter; and so on.

[279]The Latin translation of Basle, 1541, says, "the lord of that sign in which the number shall terminate."

[280]Whalley says here, "let a sign be added for each month to the sign of the year. So, in the example before proposed, the last 15° of Gemini, and the first 15° of Cancer, shall serve for the first month: the last 15° of Cancer and the first 15° of Leo, for the second month; and so on. And for days, from 15° of Gemini to 15° of Cancer, rules two days and eight hours after birth, &c."

Placidus is of opinion, “that Ptolemy, speaking of annual places, is to be understood of the places of secondary directions; and that when he speaks of the menstrual, he hints at the places of progressions.” (Cooper’s Translation, pp. 25 and 57.)

[281]Placidus says, that “active ingresses, if they be similar, to the pre-ordained effects, cause them to influence; if dissimilar, they either diminish or retard; as Ptolemy has it in the last Chapter of Book IV.” (Cooper’s Translation, p. 27.)

[282]Placidus observes, that “the primary directions of the significators to their promittors, and the lords of the terms, Ptolemy calls the General Arbiters of Times, because they pre-ordain the general times of their effects; which, as its motion is slow and its perseverance long, discovers its effects after a very long time; that is, after months and years. In order that we may know, in this extent of time, on what particular month and day the effects appear, Ptolemy proposes these motions for observation, wherein, when the majority of the causes agree together, then doubtless the effect is accomplished, or most clearly manifests itself.” (Cooper’s Translation, p. 109.) And he says afterwards, in speaking of secondary directions, progressions, ingresses, &c., “these subsequent motions of the causes demand our greatest attention.” (*Ibid.*, p. 110.) In the Appendix to the same book, at p. 438, the proper equation of time, or measurement of the arcs of direction, is also treated of, in reference to the 16th canon of Placidus, which is as follows:—

“*To equate the Arc of Direction.* Add the arc of direction to the right ascension of the natal Sun; look for this sum in the table of right ascensions under the ecliptic, and take the degree and minute of longitude corresponding with that sum; then, in the best ephemeris, reckon in how many days and hours the Sun, from the day and hour of birth, has arrived at that degree and minute. The number of days indicate as many years; every two hours over, reckon a month.” (*Ibid.*, p. 55.)

[283]Whether general or annual.

[284]That is to say, by the opposition, trine, &c.

[285]On this side of the equator.

[286]Thus (according to the Table inserted at p. 152), in the climate or latitude of Lower Ægypt, the times of ascension between the first point of Gemini and the first point of Sagittarius, diametrically opposite, are 205° 18′, which, being divided by 15, give 13 hours 41 minutes and a fraction of equatorial time, as the length of the day of the first point of Gemini. And the same

number of times of ascension, divided by 12, give 17° 6′ and a fraction of the equator, as the length of the diurnal temporal hour. In the latitude of Southern Britain, the times of ascension between the same points as above mentioned are 236° 2′, which, divided by 15, give 15 hours 44 minutes and a fraction of equatorial time, as the length of the day of the first point of Gemini; and, if divided by 12, they produce 19° 40′ and a fraction of the equator, as the length of the diurnal temporal hour.

[287]Thus, the aggregate times of ascension, in a right sphere, of the first point of Gemini are 57° 44′; and, in the climate of Lower Ægypt, 45° 5′: the sixth part of the difference between them is 2° 6′ and a fraction, which, added to 15°, again makes the diurnal temporal hour of the first point of Gemini equal to 17° 6′ and a fraction of the equator. In the climate of Southern Britain, the aggregate times of ascension of the first point of Gemini are 29° 43′: the sixth part of the difference between that sum and 57° 44′ of right ascension is 4° 40′ and a fraction, which, added to 15°, makes the diurnal temporal hour of the first point of Gemini, in South Britain, equal to 19° 40′ and a fraction of the equator, as before shown.

[288]For example,

Diurnal horary times of the first point of Gemini in the latitude of Alexandria	17°	6′	30″
Number of temporal hours			12
	15)205	18	0
Diurnal equatorial hours of the first point of Gemini in the latitude of Alexandria	13	41	12
Diurnal horary times of the first point of Gemini in the latitude of Southern Britain	19°	40′	10″
Number of temporal hours			12
	15)236	2	0
Diurnal equatorial hours of the first point of Gemini in the latitude of Southern Britain	15	44	8

zain n. adwan

[289]Let the first point of Gemini be on the meridian above the earth; the number of temporal hours since sunrise will then be 6, by which 17° 6′ 30″ are to multiplied. The product will be 102° 39′: this, added to 45° 5′, the aggregate number of the first point of Gemini in the latitude of Alexandria, will give 147° 44′, which, in the ascensions of the climate in question, will correspond to the 3d degree of Virgo, and show that to be the degree ascending. In the latitude of Southern Britain the total number would still amount to the same, viz. 147° 44′, but it would show 7° and about 30′ of Virgo to be ascending.

[290]Let the first point of Gemini be three temporal hours past the meridian; these hours reduced to degrees, in the latitude of Alexandria, will give 51° 19′, which, added to the right ascension of the first point of Gemini, make 109° 3′, showing the 18th degree of Cancer on the meridian. In the latitude of Southern Britain, these hours would produce 59°, which, added to the right ascension, would make 116° 44′, and show the 25th degree of Cancer on the meridian.

[291]Thus, in the latitude of Alexandria, when the first point of Gemini is three temporal hours past the meridian, the 16th degree of Libra will be on the ascendant, and the aggregate times of ascension of that degree in the said latitude are 109° 3′: by subtracting 90 from this sum, the remainder will be 19° 3′, the right ascension of the mid-heaven answering to the 18th degree of Cancer. In the latitude of Southern Britain, the 18th degree of Libra would be on the ascendant, of which degree the aggregate times of ascension in that latitude are 206° 44′, from which, if 90 be subtracted, the remainder will be 116° 44′, the right ascension of the mid-heaven answering to the 25th degree of Cancer. The converse of these operations seems too obvious to need explanation.

[292]Alexandria.

[293]Southern Britain.

[294]Moxon’s Mathematical Dictionary says, that the “Centiloquium is a book containing one hundred astrological aphorisms, commonly ascribed to Ptolemy, as its author, but by some to Hermes Trismegistus.” This account, however, seems to be inaccurate; for the Centiloquy attributed to Osiris’s contemporary and counsellor (eulogized by Lilly as having been “one of the wisest of all mortal men, and as ancient as Moses”), is very different from that known by the name of the Καρπος, or “Fruit of the Tetrabiblos.” Whether this latter Centiloquy be really the work of Ptolemy is another question: it has been usually edited as his, but some of the aphorisms seem to

relate to horary questions only, which are not adverted to in the Tetrabiblos, and there are others also which do not appear to result from the doctrine of that book.

[295]Of the same degree and sign.

[296]Or in obscure situations.

[297]Of the Sun and Moon.

[298]On this aphorism Partridge has said, “how Ptolemy meant it to be understood, I know not; and so I leave it.”

[299]Or part of heaven indicating the grant.

PLEASE READ THIS BEFORE YOU DISTRIBUTE OR USE THIS WORK

To protect the Project Gutenberg™ mission of promoting the free distribution of electronic works, by using or distributing this work (or any other work associated in any way with the phrase "Project Gutenberg"), you agree to comply with all the terms of the Full Project Gutenberg License available with this file or online at www.gutenberg.org/license.

Section 1. General Terms of Use and Redistributing Project Gutenberg electronic works

1.A. By reading or using any part of this Project Gutenberg electronic work, you indicate that you have read, understand, agree to and accept all the terms of this license and intellectual property (trademark/copyright) agreement. If you do not agree to abide by all the terms of this agreement, you must cease using and return or destroy all copies of Project Gutenberg electronic works in your possession. If you paid a fee for obtaining a copy of or access to a Project Gutenberg electronic work and you do not agree to be bound by the terms of this agreement, you may obtain a refund from the person or entity to whom you paid the fee as set forth in paragraph 1.E.8.

1.B. "Project Gutenberg" is a registered trademark. It may only be used on or associated in any way with an electronic work by people who agree to be bound by the terms of this agreement. There are a few things that you can do with most Project Gutenberg electronic works even without complying with the full terms of this agreement. See paragraph 1.C below. There are a lot of things you can do with Project Gutenberg electronic works if you follow the terms of this agreement and help preserve free future access to Project Gutenberg electronic works. See paragraph 1.E below.

1.C. The Project Gutenberg Literary Archive Foundation ("the Foundation" or PGLAF), owns a compilation copyright in the collection of Project Gutenberg electronic works. Nearly all the individual works in the collection are in the public domain in the United States. If an individual work is unprotected by copyright law in the United States and you are located in the United States, we do not claim a right to prevent you from copying, distributing, performing, displaying or creating derivative works based on the work as long as all references to Project Gutenberg are removed. Of course, we hope that you will support the Project Gutenberg mission of promoting free access to electronic works by freely sharing Project Gutenberg works in compliance with the terms of this agreement for keeping the Project Gutenberg name associated with the work. You can easily comply with the terms of this agreement by keeping this work in the same format with its attached full Project Gutenberg License when you share it without charge with others.
1.D. The copyright laws of the place where you are located also govern what you can do with this work. Copyright laws in most countries are in a constant state of change. If you are outside the United States, check the laws of your country in addition to the terms of this agreement before downloading, copying, displaying, performing, distributing or creating derivative works based on this work or any other Project Gutenberg work. The Foundation makes no representations concerning the copyright status of any work in any country other than the United States.
1.E. Unless you have removed all references to Project Gutenberg:
1.E.1. The following sentence, with active links to, or other immediate access to, the full Project Gutenberg License must appear prominently whenever any copy of a Project Gutenberg work (any work on which the phrase "Project Gutenberg" appears, or with which the phrase "Project Gutenberg" is associated) is accessed, displayed, performed, viewed, copied or distributed:
This eBook is for the use of anyone anywhere in the United States and most other parts of the world at no cost and with almost no restrictions whatsoever. You may copy it, give it away or re-use it under the terms of the Project Gutenberg™ License included with this eBook or online at www.gutenberg.org. If you are not located in the United States, you will have to check the laws of the country where you are located before using this eBook.

1.E.2. If an individual Project Gutenberg electronic work is derived from texts not protected by U.S. copyright law (does not contain a notice indicating that it is posted with permission of the copyright holder), the work can be copied and distributed to anyone in the United States without

paying any fees or charges. If you are redistributing or providing access to a work with the phrase “Project Gutenberg” associated with or appearing on the work, you must comply either with the requirements of paragraphs 1.E.1 through 1.E.7 or obtain permission for the use of the work and the Project Gutenberg trademark as set forth in paragraphs 1.E.8 or 1.E.9.

1.E.3. If an individual Project Gutenberg electronic work is posted with the permission of the copyright holder, your use and distribution must comply with both paragraphs 1.E.1 through 1.E.7 and any additional terms imposed by the copyright holder. Additional terms will be linked to the Project Gutenberg License for all works posted with the permission of the copyright holder found at the beginning of this work.

1.E.4. Do not unlink or detach or remove the full Project Gutenberg License terms from this work, or any files containing a part of this work or any other work associated with Project Gutenberg.

1.E.5. Do not copy, display, perform, distribute or redistribute this electronic work, or any part of this electronic work, without prominently displaying the sentence set forth in paragraph 1.E.1 with active links or immediate access to the full terms of the Project Gutenberg License.

1.E.6. You may convert to and distribute this work in any binary, compressed, marked up, nonproprietary or proprietary form, including any word processing or hypertext form. However, if you provide access to or distribute copies of a Project Gutenberg work in a format other than “Plain Vanilla ASCII” or other format used in the official version posted on the official Project Gutenberg website (www.gutenberg.org), you must, at no additional cost, fee or expense to the user, provide a copy, a means of exporting a copy, or a means of obtaining a copy upon request, of the work in its original “Plain Vanilla ASCII” or other form. Any alternate format must include the full Project Gutenberg License as specified in paragraph 1.E.1.

1.E.7. Do not charge a fee for access to, viewing, displaying, performing, copying or distributing any Project Gutenberg works unless you comply with paragraph 1.E.8 or 1.E.9.

1.E.8. You may charge a reasonable fee for copies of or providing access to or distributing Project Gutenberg electronic works provided that:

- • You pay a royalty fee of 20% of the gross profits you derive from the use of Project Gutenberg works calculated using the method you already use to calculate your applicable taxes. The fee is owed to the owner of the Project Gutenberg trademark, but he has agreed to donate royalties under this paragraph to the Project Gutenberg Literary

zain.adwan

Archive Foundation. Royalty payments must be paid within 60 days following each date on which you prepare (or are legally required to prepare) your periodic tax returns. Royalty payments should be clearly marked as such and sent to the Project Gutenberg Literary Archive Foundation at the address specified in Section 4, "Information about donations to the Project Gutenberg Literary Archive Foundation."

- • You provide a full refund of any money paid by a user who notifies you in writing (or by e-mail) within 30 days of receipt that s/he does not agree to the terms of the full Project Gutenberg™ License. You must require such a user to return or destroy all copies of the works possessed in a physical medium and discontinue all use of and all access to other copies of Project Gutenberg™ works.

- • You provide, in accordance with paragraph 1.F.3, a full refund of any money paid for a work or a replacement copy, if a defect in the electronic work is discovered and reported to you within 90 days of receipt of the work.

- • You comply with all other terms of this agreement for free distribution of Project Gutenberg™ works.

1.E.9. If you wish to charge a fee or distribute a Project Gutenberg™ electronic work or group of works on different terms than are set forth in this agreement, you must obtain permission in writing from the Project Gutenberg Literary Archive Foundation, the manager of the Project Gutenberg™ trademark. Contact the Foundation as set forth in Section 3 below.

1.F.

1.F.1. Project Gutenberg volunteers and employees expend considerable effort to identify, do copyright research on, transcribe and proofread works not protected by U.S. copyright law in creating the Project Gutenberg™ collection. Despite these efforts, Project Gutenberg™ electronic works, and the medium on which they may be stored, may contain "Defects," such as, but not limited to, incomplete, inaccurate or corrupt data, transcription errors, a copyright or other intellectual property infringement, a defective or damaged disk or other medium, a computer virus, or computer codes that damage or cannot be read by your equipment.

1.F.2. LIMITED WARRANTY, DISCLAIMER OF DAMAGES - Except for the "Right of Replacement or Refund" described in paragraph 1.F.3, the Project Gutenberg Literary Archive

zain. adwan

Foundation, the owner of the Project Gutenberg™ trademark, and any other party distributing a Project Gutenberg™ electronic work under this agreement, disclaim all liability to you for damages, costs and expenses, including legal fees. YOU AGREE THAT YOU HAVE NO REMEDIES FOR NEGLIGENCE, STRICT LIABILITY, BREACH OF WARRANTY OR BREACH OF CONTRACT EXCEPT THOSE PROVIDED IN PARAGRAPH 1.F.3. YOU AGREE THAT THE FOUNDATION, THE TRADEMARK OWNER, AND ANY DISTRIBUTOR UNDER THIS AGREEMENT WILL NOT BE LIABLE TO YOU FOR ACTUAL, DIRECT, INDIRECT, CONSEQUENTIAL, PUNITIVE OR INCIDENTAL DAMAGES EVEN IF YOU GIVE NOTICE OF THE POSSIBILITY OF SUCH DAMAGE.

1.F.3. LIMITED RIGHT OF REPLACEMENT OR REFUND - If you discover a defect in this electronic work within 90 days of receiving it, you can receive a refund of the money (if any) you paid for it by sending a written explanation to the person you received the work from. If you received the work on a physical medium, you must return the medium with your written explanation. The person or entity that provided you with the defective work may elect to provide a replacement copy in lieu of a refund. If you received the work electronically, the person or entity providing it to you may choose to give you a second opportunity to receive the work electronically in lieu of a refund. If the second copy is also defective, you may demand a refund in writing without further opportunities to fix the problem.

1.F.4. Except for the limited right of replacement or refund set forth in paragraph 1.F.3, this work is provided to you 'AS-IS', WITH NO OTHER WARRANTIES OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO WARRANTIES OF MERCHANTABILITY OR FITNESS FOR ANY PURPOSE.

1.F.5. Some states do not allow disclaimers of certain implied warranties or the exclusion or limitation of certain types of damages. If any disclaimer or limitation set forth in this agreement violates the law of the state applicable to this agreement, the agreement shall be interpreted to make the maximum disclaimer or limitation permitted by the applicable state law. The invalidity or unenforceability of any provision of this agreement shall not void the remaining provisions.

1.F.6. INDEMNITY - You agree to indemnify and hold the Foundation, the trademark owner, any agent or employee of the Foundation, anyone providing copies of Project Gutenberg™ electronic works in accordance with this agreement, and any volunteers associated with the production, promotion and distribution of Project Gutenberg™ electronic works, harmless from

Zain.adwan

all liability, costs and expenses, including legal fees, that arise directly or indirectly from any of the following which you do or cause to occur: (a) distribution of this or any Project Gutenberg work, (b) alteration, modification, or additions or deletions to any Project Gutenberg work, and (c) any Defect you cause.

Section 2. Information about the Mission of Project Gutenberg

Project Gutenberg is synonymous with the free distribution of electronic works in formats readable by the widest variety of computers including obsolete, old, middle-aged and new computers. It exists because of the efforts of hundreds of volunteers and donations from people in all walks of life.

Volunteers and financial support to provide volunteers with the assistance they need are critical to reaching Project Gutenberg's goals and ensuring that the Project Gutenberg collection will remain freely available for generations to come. In 2001, the Project Gutenberg Literary Archive Foundation was created to provide a secure and permanent future for Project Gutenberg and future generations. To learn more about the Project Gutenberg Literary Archive Foundation and how your efforts and donations can help, see Sections 3 and 4 and the Foundation information page at www.gutenberg.org.

Section 3. Information about the Project Gutenberg Literary Archive Foundation

The Project Gutenberg Literary Archive Foundation is a non-profit 501(c)(3) educational corporation organized under the laws of the state of Mississippi and granted tax exempt status by the Internal Revenue Service. The Foundation's EIN or federal tax identification number is 64-6221541. Contributions to the Project Gutenberg Literary Archive Foundation are tax deductible to the full extent permitted by U.S. federal laws and your state's laws.

The Foundation's business office is located at 41 Watchung Plaza #516, Montclair NJ 07042, USA, +1 (862) 621-9288. Email contact links and up to date contact information can be found at the Foundation's website and official page at www.gutenberg.org/contact

Section 4. Information about Donations to the Project Gutenberg Literary Archive Foundation

Project Gutenberg™ depends upon and cannot survive without widespread public support and donations to carry out its mission of increasing the number of public domain and licensed works that can be freely distributed in machine-readable form accessible by the widest array of

Zaid n. adwan

equipment including outdated equipment. Many small donations ($1 to $5,000) are particularly important to maintaining tax exempt status with the IRS.

The Foundation is committed to complying with the laws regulating charities and charitable donations in all 50 states of the United States. Compliance requirements are not uniform and it takes a considerable effort, much paperwork and many fees to meet and keep up with these requirements. We do not solicit donations in locations where we have not received written confirmation of compliance. To SEND DONATIONS or determine the status of compliance for any particular state visit www.gutenberg.org/donate.

While we cannot and do not solicit contributions from states where we have not met the solicitation requirements, we know of no prohibition against accepting unsolicited donations from donors in such states who approach us with offers to donate.

International donations are gratefully accepted, but we cannot make any statements concerning tax treatment of donations received from outside the United States. U.S. laws alone swamp our small staff.

Please check the Project Gutenberg web pages for current donation methods and addresses. Donations are accepted in a number of other ways including checks, online payments and credit card donations. To donate, please visit: www.gutenberg.org/donate.

Section 5. General Information About Project Gutenberg electronic works

Professor Michael S. Hart was the originator of the Project Gutenberg concept of a library of electronic works that could be freely shared with anyone. For forty years, he produced and distributed Project Gutenberg eBooks with only a loose network of volunteer support.

Project Gutenberg eBooks are often created from several printed editions, all of which are confirmed as not protected by copyright in the U.S. unless a copyright notice is included. Thus, we do not necessarily keep eBooks in compliance with any particular paper edition.

Most people start at our website which has the main PG search facility: www.gutenberg.org.

This website includes information about Project Gutenberg, including how to make donations to the Project Gutenberg Literary Archive Foundation, how to help produce our new eBooks, and how to subscribe to our email newsletter to hear about new eBooks.

Preface to the Revised and Enlarged Edition

Since the publication of this small manual of practical Astrology, two editions of which have been exhausted, the attention given to the subject has so far extended as to create an increased demand for a concise work of this nature, designed for the initial use of students and offered at a price that is within the means of all. It is believed that the revision and enlargement of the present work will render it even more popular than hitherto with beginners.

The practical uses of Astrology are daily more and more recognized and appreciated, and although some of the higher and later developments of Astrology in its relation to every-day problems have necessarily been withheld from these pages, yet it is to be hoped that so much as is here presented of an abstruse and recondite science will enable the student to pursue the subject with increasing assurance and satisfaction, in which case doubtless he will readily discover for himself, and without any special pointing on my part, that Astrology is primarily and finally a practical and useful study.

There are, of course, many aspects of this fascinating subject which find no place in this small work, which deals solely with Genethliacal Astrology, or the doctrine of Nativities. Yet if it be true, as I think to be the case, that “the proper study for mankind is man,” then undoubtedly we are right in selecting this phase of Astrological Science as that to which the student should first devote himself.

Zain ul adwan

When we have thoroughly arrived at an understanding of the complex nature of human character and the primary causes of variety in expression, when we have seen[Pg 6] for ourselves how the many-coloured dome of Life overarches us of this sublunary world with its kaleidoscopic interplay of forces, we shall be to some extent better equipped not only to deal with character as we find it, but also to direct the forces of the human mind along channels which lead to the preservation of our social economy, and that not by any restrictive measures or harmful suppression of natural passions and powers, but by conversion of them into forms that are conservative and useful.

To apply oneself to the specialization of inherent faculty, to find the line of least resistance, and to discover the measure of one's own soul in the universe and the limit to which ambition can safely aspire, these are things necessary to be known and things that Astrology makes clear to the mind in the very earliest stages of our study.

And apart from the scientific verities to which the science of planetary influence directs us, there are other not less important and fascinating truths of a purely philosophic nature to which it inevitably impels the mind and which cannot fail to exercise a tremendous influence in the shaping of our thought in regard to the purpose of life. It places the thoughtful student in an entirely new position with regard to many of the deeper problems of existence, and it is certainly the fact that to those who newly come to its study, Astrology is a revelation, an enlightenment, and a conviction from which there is no possible or desirable escape.

SEPHARIAL.

[Pg 9]

Introduction

From the earliest ages of the world's history the subject of Astrology has excited the interest of, and exercised a great influence over, the minds of a certain order of thinking men. The science has never been universal in its acceptance, though it is safe to say that, with its countless adherents in the East and the ever-increasing number of its advocates in the West, there is no faith which has a more universal application than the belief in the influence of the heavenly bodies over the destinies of human beings. It is not possible within the limits of a small handbook such as this to adequately consider the philosophic paradox which makes of Freewill in man a "necessity in play"; but it is obvious that the concept is not altogether unscientific, seeing that it is customary to speak of the "free path of vibration" in chemical atoms while at the same time it is known that these atoms have their restricted characteristics, modes of motion, &c., and are all subject to the general laws controlling the bodies of which they form integral parts. Let it suffice that if we can trace an actual connectedness between the disposition of the heavenly bodies at the moment of a birth and the known life and character of[Pg 10] the individual then born, and an exact correspondence between the course of events in that life with the changes occurring in the heavens subsequent to the moment of birth, we shall do well to accept the fact for what it is worth, and arrange our philosophic notions accordingly.

As far back as the year B.C. 2154, we find mention of the great importance attaching to the celestial phenomena in the minds of Chinese rulers. It is recorded in the Historical Classic of China that at that time the astrologers Hi and Ho neglected their duties so

zain.adwan

that when, on the 10th of October, there was a great eclipse of the Sun at Peking between seven and nine o'clock in the morning, the people were wholly unprepared for it, and "ran about here and there in the utmost consternation." For this offence Hi and Ho were deprived of their offices, their estates were confiscated and they were driven from the kingdom. Among the Hindus we have the classical writers Garga, Parashara, and Mihira, together with their legions of commentators. The Assyrian records are full of astrological allusions regarding the influence of planetary conjunctions and stellar positions. The Greek mythology is nothing but a vast system of cosmographical astrology, and there is no other history in it than what you may read in the constellations of the heavens and the corresponding evolution of the human race. Aristotle made it a part of his philosophy. Hipparchus, Hippocrates, Thales, Galenius, and others subscribed an intelligent belief in its principles. To Claudius Ptolemy, however, we are indebted for the first concise and scientific statement of its principles and practice, so far as Europe is concerned. He wrote the[Pg 11] Tetrabiblos, or Four Books, and laid the foundations of a true astrological science. Julius Firmicus confirmed Ptolemy and enlarged upon his observations. The subsequent discovery of the planets Uranus and Neptune by Herschel and Adams, widened the field of research and gave to later astrologers the clue to much that hitherto had been imperfectly understood. Not that these discoveries overturned the whole system of astrology, as some have imagined and foolishly stated, or that they negatived the conclusions drawn from the observed effects of the seven anciently known bodies of the solar system, but it became possible after a lapse of time to fill in the blank spaces and to account for certain events which had not been traced to the action of any of the already known planets. The discovery of argon did not destroy our conclusions regarding the nature and characteristics of oxygen or hydrogen or nitrogen, nor give an entirely new meaning to the word "atmosphere." If even so many as seven new planets should be discovered, there would yet not be a single paragraph of this book which would need revising. What is known regarding planetary action in human life is known with great certainty, and the effects of one planet can

never be confounded with those of another. Incomplete as it must needs be, it is yet a veritable science both as to its principles and practice. It claims for itself a place among the sciences for the sole reason that it is capable of mathematical demonstration, and deals only with the observed positions and motions of the heavenly bodies; and the man who holds to the principia of Newton, the solidarity of the solar system, the interaction of the planetary bodies and their consequent electrostatic effects[Pg 12] upon the Earth, cannot, while subject to the air he breathes, deny the foundation principles of astrology. The application of these principles to the facts of everyday life is solely a matter of prolonged research and tabulation upon an elaborate scale which has been going on for thousands of years in all parts of the world, so that all the reader has to do is to make his own horoscope and put the science to the test of true or false. The present writer is in a position to know that the study of astrology at the present day is no less sincere than widely spread, but few care to let their studies be known, for, as Prof. F. Max Müller recently said, "So great is the ignorance which confounds a science requiring the highest education, with that of the ordinary gipsy fortune-teller." That to which the great Kepler was compelled "by his unfailing experience of the course of events in harmony with the changes taking place in the heavens," to subscribe "an unwilling belief," the science which was practised and advocated by Tycho Brahe under all assaults of fortune and adverse opinion, the art that arrested the attention of the young Newton and set him pondering upon the problems of force and matter, which fascinated the minds of such men as Francis Bacon, Archbishop Usher, Haley, Sir George Witchell, Flamstead, and a host of others, is to-day the favourite theme of thousands of intelligent minds and bids fair to become a subject of popular inquiry.

It is believed that the present work will be of considerable assistance to those who seriously contemplate an initial study of the science of horoscopy, and although it by no means exhausts what is known on the subject, yet it will be found accurate and reliable as far as it goes,[Pg 13] and will enable any one of ordinary intelligence to test the

claims of Astrology for himself. This is as much as can be expected in the limits of a small handbook. The literature of the subject is considerable, and the present writer only takes credit to himself so far as his own wide experience and practice have enabled him to present the subject in a simple and brief manner.

THE ALPHABET OF THE HEAVENS

CHAPTER I

THE PLANETS, THEIR NATURES AND TYPES

zaid n. adwan

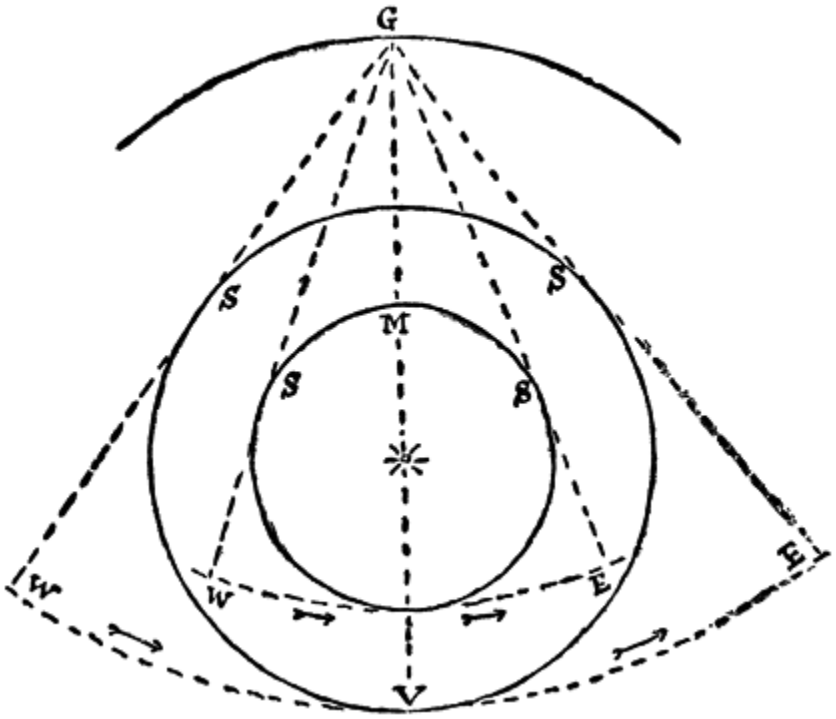
The luminaries and planets are known to astronomers under the following names and symbols:—

The Sun ⊙, Moon ☽, Neptune ♆, Uranus ♅, Saturn ♄, Jupiter ♃, Mars ♂, Venus ♀, and Mercury ☿.

Neptune revolves around the Sun in its distant orbit once in about 165 years. Uranus completes its orbital revolution in 84 years, Jupiter in 12 years, Mars in about 15 months, Venus in 11 months, and Mercury in 18 weeks. If you imagine these bodies to be revolving in a plane around the Sun and yourself to be standing within the Sun, the motions of these bodies will appear almost uniform and always in one direction. Were the orbits of the planets circular and the Sun holding the centre of the circle, their motions would be constant, that is to say, always in the same direction and at the same rate. But the orbits are elliptical, and the Sun holds a position in one of the foci of each[Pg 18] ellipse. Consequently the planets are at times further from the Sun than at others, and they are then said to be in their aphelion, the opposite point of the orbit where they are nearest to the Sun being called the perihelion. When at aphelion the planets move slower, and when at perihelion they move quicker than at the mean distance. Astronomers employ an imaginary circular orbit for the planets, in which they move at an uniform rate of velocity, which is called the mean motion. This is subject to an equation depending on the position of the planet in its orbit, and it determines the difference between the imaginary planet and the true planet. The equation itself depends on the eccentricity of the orbit, that is to say, its relation to a circle drawn around the same focal centre. The Earth follows the same laws as all other bodies of the same system.

But if we imagine the Earth to be stationary in space and the centre around which the planets revolve, their motions present several irregularities. Mercury and Venus will then appear to revolve around the Sun while the Sun revolves around the Earth, sometimes being between the Earth and the Sun, which is called an Inferior conjunction,

sometimes on the further side of the Sun away from the Earth, as at their Superior conjunction; and again, at other times to the right or left of the Sun, in East or West elongation. The other planets, having orbits greater than that of the Earth, will appear to revolve around it at constantly varying distances and velocities. At certain points in their orbits they will appear to remain stationary in the same part of the Zodiac. The annexed illustration will assist the lay reader perhaps. The body M is Mercury[Pg 19] when at Inferior conjunction with the Sun, as seen from the Earth. The letter V is the planet Venus at Superior conjunction with the Sun. The points W and E are the points of greatest elongation West and East, and the letter S shows the points in the orbit at which those bodies appear to be stationary when viewed from the Earth, at G. As seen from the Earth, Venus would appear to be direct and Mercury retrograde.



Astrologically we regard the Earth as the passive subject of planetary influence, and we have therefore to regard it as the centre of the field of activity. If we were making a horoscope for an inhabitant of the planet Mars, we should make Mars the centre of the system. The planets' positions are therefore taken as from the centre of the Earth

(Geocentric), and not[Pg 20] as from the centre of the Sun (Heliocentric). An astrological Ephemeris of the planets' motions is employed for this purpose (see Sect. II., chap, i.), and there are 480,000 of these sold to astrologers or students of astrology every year, from which fact it is possible to draw one's own conclusions as to the state of Astrology in the West. These figures, of course, do not include the millions of almanac readers nor the Oriental students, who prepare their own ephemerides.

Knowing the simple natures of the several planets we are able to arrive at an estimate of their effects when acting in combination.

Neptune acts upon the mind of man to produce a highly-strung nervous temperament, often allied to either insanity or genius; neurosis, aphasia, &c. It produces complications in business and an involved state of affairs generally. Disposes to fraud, double-dealing, and irresponsible actions. In the body it produces waste of tissue and a consumptive habit.

Uranus gives an eccentric mind, waywardness, originality, inventiveness. Acting on the affairs of business, it produces sudden and unexpected developments, irregularities, rapid rise and fall, instability, unexpected turns of good and bad fortune. In the body it has relation to the nervous system, and its diseases are those of paralysis, lesion, and nervous derangement.

Saturn produces a thoughtful, sober, ponderable mind; steadfastness, patience, and endurance; disposition to routine and habit, method. In financial affairs it gives steady results commensurate with labour, success that is slow but sure, durance, hardships, privations. In the body it is related to the osseous[Pg 21] system, and its effects are brought about by obstructions, chills, and inhibition of function.

Jupiter gives joviality, optimism, bountifulness, generosity, a rich and fruitful mind. It renders the subject fortunate in his affairs, giving success and frequently opulence. With this planet strong in the horoscope a person never "goes under." In the body it has

relation to the arterial process, and its diseases are those which arise from surfeit, congestion, and plethora.

Mars confers a sense of freedom, much ambition and executive ability, frankness, truthfulness, and scorn of consequence. It renders the mind forceful and militant, stimulates to new projects and enterprises, and in the body of man has relation to the muscular system. Its diseases are those which arise from inflammatory action in the tissues.

Venus confers poesy, good taste, fine feeling, artistic powers, gentleness, docility, dalliance, and love of pleasure. It renders the affairs pleasant and prosperous, giving profit from both artistic and rustic pursuits. Next to Jupiter it is the most benefic of the planets in its action on mankind. In the body it has relation to the venous system, and its diseases are those which arise from impurities of the blood, scorbutic and zymotic diseases, eczema, smallpox, measles, &c.

Mercury renders its subjects active, versatile, apt and business-like, disposed to much commerce, whether of the mind or the market, and eager in the pursuit of knowledge; alert, and well-informed. Its influence on affairs of life is variable, for it always translates the nature of that planet to which at birth it is in nearest aspect (Sect. I., chap. iv.). In the body it is[Pg 22] related to the sensorium, the centres of sensation, and reflexly controls the nerves of action.

The Moon gives gracefulness of manner and suavity of speech, softness and adaptability of nature, variableness, love of change, romance, and adventure; disposed to exploration and voyaging. In the body it corresponds to the glandular system, and its diseases are those incidental to the lymphatic glands and vascular tissue.

The Sun renders its subjects magnanimous, noble, proud, despising all mean and sordid actions; loyal, truthful, and fearless. It produces honours and the favour of dignitaries,

and renders the subject fortunate in the control of his affairs. In the body it controls the vital principle.

The types of persons produced by the various planets are very distinct, the chief features of each being as follows:—

Neptune—Thin, nervous-looking people, blue eyes, soft, silky hair, thin and usually long faces, frequently wearing a strained or startled look. *Uranus*—Tall, wiry, and energetic figures, alert, muscular, spasmodic, and with some touch of eccentricity. *Saturn*—Dark and lean people, small, deep-set eyes, heavy brows, long noses, thin lips, and sallow complexions. *Jupiter*—Full bodied, robust men, large and expressive blue or brown eyes, arched brows, high foreheads, oval faces, and rich brown hair. *Mars*—Strong, muscular, and athletic bodies, ruddy complexion, grey eyes, prominent brows, sloping forehead, and usually some mark or scar in the face. *Sun*—Fresh, clear complexion, blue or grey eyes, round head, broad shoulders, strong jaws, upright and dignified carriage. *Venus*—Elegant, well-groomed,[Pg 23] and often dainty-looking people, with blue or soft brown eyes, brown hair, fine teeth and finger-nails, small feet and short fleshy hands. *Mercury*—Thin, tall, and active bodies, alert appearance, small and usually dark eyes; wide, thin lips, long arms and slender hands. Frequently great talkers and quick walkers. *Moon*—Rather short and fleshy people, with pale face, soft limpid eyes, sad brown or medium coloured hair, fine teeth, broad chest, and a tendency to a squat fulness of body. The forehead is usually high and broad.

Look at the people as they pass you in the street. Bring them if possible under one or other of these types. Consider what has been said of the planets' natures, and you have a ready key to something of their character and destiny.

[Pg 24]

zain.adwan

CHAPTER II

THE SIGNS OF THE ZODIAC

The Zodiac is an imaginary belt of the Heavens through which the Sun and planets move in their apparent revolutions round the Earth. It extends from 23° 27′ above the plane of the Equator to the same distance below it, being bounded by the Tropic of Cancer on the North and by that of Capricorn on the South. The Ecliptic is a circle transecting this belt at an angle of 23° 27′ to the plane of the Equator. The points where it cuts the Equator are called the Equinoxes.

The Ecliptic is divided into twelve equal sections, counting from the Vernal Equinox. These are called the Signs of the Zodiac. Each sign occupies 30 degrees of the circle.

Their names and symbols are as follows:—

1. Aries, the Ram ♈
2. Taurus, the Bull ♉
3. Gemini, the Twins ♊
4. Cancer, the Crab ♋
5. Leo, the Lion ♌
6. Virgo, the Virgin ♍
7. Libra, the Balance ♎
8. Scorpio, the Scorpion ♏
9. Sagittarius, the Hunter ♐
10. Capricornus, the Goat ♑
11. Aquarius, the Waterman ♒
12. Pisces, the Fishes ♓

zaid n. adwan

[Pg 25]

For Astrological purposes they are grouped according to the element and the constitution which they represent, thus:—

ELEMENTS.

Fire—Aries, Leo, Sagittarius.

Earth—Taurus, Virgo, Capricornus.

Air—Gemini, Libra, Aquarius.

Water—Cancer, Scorpio, Pisces.

CONSTITUTIONS.

Movable—Aries, Cancer, Libra, Capricornus.

Fixed—Taurus, Leo, Scorpio, Aquarius.

Flexed—Gemini, Virgo, Sagittarius, Pisces.

Every alternate sign, beginning with Aries, is male and the rest are female. Aries, male; Taurus, female; Gemini, male; Cancer, female, &c. The signs Aries, Leo, Capricornus are called barren, while Taurus, Cancer, Scorpio, and Pisces are fruitful. Aries governs the East, Cancer the North, Libra the West, and Capricornus the South.

zaid n. adwan

The Double-bodied signs are Gemini, Sagittarius, and Pisces. It is important that all these classifications should be learned, as they form an essential part of the doctrine of Astrology, and are frequently employed in the reading of a Horoscope.

The types of people under the various signs should also be known as intimately as possible. A person is said to be "under" a sign—that is to say, under its influence, when that sign is rising in the East at the[Pg 26] moment of birth. You will recognise these types among your friends and associates:—

Aries produces a person of lean body, long neck, high cheek-bones, grey eyes, sandy or sad brown hair, which is either wiry and straight or crisp and curling. The front teeth are usually large and prominent.

Taurus gives a full, thick-set body, strong neck and shoulders, full brown eyes, dark curling hair, full lips, rather wide mouth, and round, bullet-shaped head. The hands and feet are short and fleshy.

Gemini produces a tall, active, and upright body, long arms and legs, wide, thin lips, straight and often *retroussé* nose, lank, straight black hair, rather wide shoulders, and thin body.

Cancer denotes a rather short, squat figure, full lymphatic body, pale complexion, round face, broad forehead, sad brown hair, large aqueous eyes, full chest, short, fleshy hands and feet.

Leo renders its subjects tall, broad shouldered, fine and manly figures, small round head, fair complexion, blue or grey eyes, flaxen or fair brown hair, upright and fearless carriage.

Virgo renders the body thin and active, the head well developed, the forehead broad, hair light brown and waving off the forehead, eyes blue, shoulders broad, the type being of an intellectual or artistic form.

zaid n. adwan

Libra gives an elegant body, well-developed limbs, fine oval face, straight nose, fine blue eyes (sometimes deep brown), flaxen or chestnut hair, beautiful complexion. The highest types of beauty are to be found under this sign.

Scorpio gives a short, thick-set, and powerful figure,[Pg 27] broad, deep chest, dusky or sallow complexion, dark curling or crisp hair, strong and rather bowed legs. This is a very virile and robust type.

Sagittarius gives a tall person, well-made figure, elegant limbs, oval and rather long face, brown or chestnut hair growing off the forehead, fine expressive eyes, rather prominent and of a dark brown or blue colour, long nose, slightly aquiline.

Capricornus produces a slight and rather ill-formed person, long and scraggy neck, prominent features, narrow chin, weak and frequently decrepit limbs, weak chest and sloping shoulders. Frequently the figure is wiry and suggestive of considerable powers of endurance. The brows are prominent, the nose long, and the face thin and hard-set.

Aquarius contributes the finest types of beauty next to Libra. The Saxon type is dominant. A tall figure, well formed and rounded, fair complexion and blue eyes, flaxen hair, straight features, well-developed chin, and fine, clear forehead.

Pisces produces one of rather short stature, short limbs, lymphatic body, pale complexion, limpid blue eyes, black or brown eyes, short nose, full lips, round face, small hands and feet.

The short signs are Taurus, Cancer, Capricornus, and Pisces. The tall signs are Gemini, Leo, Sagittarius, and Aquarius. The others are of medium height.

The planets rising in each sign will always alter the type by impressing their own characteristics on the subject.

Each sign has a Ruler, and the position of the ruler of the rising sign has much to do with the physical confor[Pg 28]mation, as if Taurus be rising and Venus, its ruler, be in

Leo, the person will be taller and fairer than indicated by Taurus alone. Pure types are very uncommon.

The rulership of the planets in the signs is as follows:—

Saturn	governs	Aquarius	and	Capricornus.
Jupiter	governs	Pisces	and	Sagittarius.
Mars	governs	Aries	and	Scorpio.
Venus	governs	Taurus	and	Libra.
Mercury	governs	Gemini	and	Virgo.

The Moon governs Cancer, and Leo is governed by the Sun.

When a planet is found in a sign over which it is said to govern it acts more strongly than usual, and when in the opposite signs to those it governs it is said to be in its "fall," when it is weaker than usual.

Planets governing opposite signs to one another are said to be "enemies." Such do not produce harmonious and favourable results when acting in conjunction.

[Pg 29]

CHAPTER III

THE CELESTIAL HOUSES

The imaginary circle which passes immediately over your head as you face the South is called the Prime Vertical. This is divided for astrological purposes into twelve equal divisions called Houses, six of which are above the horizon and six below it. They are counted from the East Horizon under the Earth to the West, and thence through the

zaid n. adwan

zenith to the East again. The figure in Section IV., chapter v., will make the idea easy of comprehension.

Each such division or House carries its own signification, and it has been ascertained beyond all doubt or cavil that the ruling of the Ancients in this matter is altogether reliable, however empirical it may appear.

The First House governs the personal appearance, but chiefly the face and head. The Second House rules over finance, movable effects, commerce. In the body it governs the neck and throat. The Third House governs short journeys, letters, and other means of communication, near relations or neighbours. In the body it governs the arms and lungs. The Fourth House governs real estate, the residence, the produce of the earth, the mother[Pg 30] of the subject, and the end of life. In the body, the breasts and thorax. The Fifth House governs progeny, the sex instincts, domestic relations, and social pleasures. In the body, the back and heart. The Sixth House governs the health, servants, and personal comforts of the subject, clothes, food, and other physical requisites, sanitation, hygiene. In the body it rules over the abdomen and lower viscera. The Seventh House has dominion over marriage, contracts, agreements, partners, and matters of exchange. In the body it has relation to the loins and kidneys. The Eighth House rules death, loss, legacies and dowries, and matters appertaining to the deceased. In the body it is related to the excretory system. The Ninth House is said to govern long journeys, publications, religious beliefs, foreign lands, and legal affairs. In the body it rules the thighs. The Tenth House rules over position, honour and fame of the subject, the father, superiors of all orders. In the body it rules over the knees. The Eleventh House governs friends, social relations, societies and companies with which the subject is concerned. In the body it has relation to the legs from calf to ankle. The Twelfth House rules ambushes, restraints, privations, imprisonments, confinements, and all limitations of the personal freedom. In the body it rules the ankles and feet.

Applying these significations to the interpretation of a horoscope it will be seen that if Mars should be rising at the moment of birth there will be a scar or mark on the face. Observations of this sort will frequently assist to determine the time of birth when it is not known. Similarly with other planets in the same or other Houses; but of this more anon.

[Pg 31]

CHAPTER IV

THE ASTRONOMICAL ASPECTS

Aspects are certain angular distances measured on the Ecliptic, and they form a fundamental part of astrological science. Any planet may be good or bad in its effects on the character and destiny, according to the aspect that it throws to the chief points of the Horoscope. The aspects are: The semisquare aspect of 45 degrees, sextile of 60 degrees, square of 90 degrees, trine of 120 degrees, sesquiquadrate of 135 degrees, and the opposition of 180 degrees. There is also the conjunction, when bodies are in the same degree or part of a Sign.

The good aspects are the trine and sextile; the evil being the semisquare, square, sesquiquadrate, and opposition. The aspect of a planet determines its effects, whether for good or evil. The conjunction is good with good planets, such as Jupiter and Venus, and evil with malefic planets such as Mars and Saturn.

When planets are the same distance North or South of the Equator they are in parallel declination (p.d.), and they then act as if in conjunction. Also when planets are in mutual

Zain Adwan

disposition, that is to say, occupying one another's signs, they act as if they were in conjunction.

[Pg 32]

Planets in conjunction act according to their simple natures, but when in aspect, according to the nature of that aspect. The benefic planets Jupiter, Venus, Sun, Moon, and also Mercury when in good disposition with another planet or in a congenial Sign, produce good effects by their conjunctions and by their trine and sextile aspects; but when in square, semisquare, or sesquisquare aspect they are uniformly evil in effect. On the other hand, the malefic planets Neptune, Uranus, Saturn, and Mars, together with Mercury when ill-disposed or in uncongenial Signs, are evil in their effects when in conjunction with the significant points of the horoscope; also when in evil aspect; but they nevertheless produce good effects when in good aspect.

The Significators.

The more important points of the Horoscope to which aspect can be thrown are called "Significators." The general significators in any horoscope are the Sun, the Moon, the Midheaven (the degree which holds the meridian of the horoscope), and the Ascendant (the degree which is rising). But every planet can be a particular significator in its own province, namely, in the Sign which it rules, and the House in which it is found at birth.

In a general sense the Moon is significant of the mother, female relations, the personal health and fortunes and the changes incident to these. The Sun in the same way indicates the father, male relations, the vital principle, and position. Mercury is the significator of the mind and intellect, the faculties generally. Venus is significatrix of love affairs, domestic relations, plea[Pg 33]sures, and of young female relations, sisters, &c. Mars is significator of enterprises, strifes, and young male relations. Jupiter is significator of increase and emoluments; Saturn of legacies, inheritance, and aged persons; Uranus of civic and governmental bodies; Neptune of voyages and psychic experiences. The chief

points to be regarded, however, are the Midheaven, the Ascendant, and the places of the Sun and Moon.

[Pg 34]

SECTION II

THE CONSTRUCTION OF A HOROSCOPE

CHAPTER I

THE EPHEMERIS AND ITS USES

An Ephemeris is an almanac of the planetary positions day by day throughout any given year. They are to be obtained at a cost of one shilling per year, in a convenient form specially adapted to the use of astrologers. In the first column will be found the Sidereal Time for the day, which is the Sun's Right Ascension or distance from the Vernal Equinox, expressed in Hours, Minutes, and Seconds, and equated to Mean Time at Greenwich. By merely adding the time after noon, or subtracting the hours and minutes before noon, at which the birth took place, you will obtain the Right Ascension of the Midheaven at the moment of birth. The use to which this is put will appear in the next chapter. It corresponds to a particular degree of the Zodiac which is in the Midheaven at the given time of birth.

Zaid Nadwan

The next column contains the Sun's longitude at Noon for each day. By taking the position on one day from[Pg 35] that on the next day, the motion of the Sun for 24 hours is obtained, and a proportion of this for the hour of birth can easily be made. The mean motion of the Sun per day is 2½′, or 1 degree per day. In another column will be found the Moon's longitude, and in adjacent columns its declination and latitude. Declination is distance North or South of the Equator, and celestial latitude is distance North or South of the Ecliptic. The longitudes of the other bodies are also given for each day at noon.

The mean longitudinal progress of the several bodies is as follows: Sun, 2½′ per hour, or 1 degree per day; Moon, 32′ per hour, or 13 degrees per day; Neptune, 2′ per day; Uranus, 3′ per day; Saturn, about 5′ per day; Jupiter, about 12′ per day; Mars, 45′ per day, or about 2′ per hour; Venus, 72′ per day, or 3′ per hour; Mercury, 84′ per day, or 3½′ per hour. These increments are for direct motion only; the planets are, as already explained, sometimes retrograde and sometimes stationary. The Horoscope of birth is only concerned with the longitudes of the planets, but when one or more planets have the same declination North or South, they should be noted as being in Parallel, for they then act as if they were in conjunction.

Take in hand, then, the Ephemeris for the year of your birth and read this chapter with it in view. After understanding its construction, extract the Sidereal Time at Noon for the day of your birth and refer to the next chapter.

[Pg 36]

CHAPTER II

TO ERECT A FIGURE OF THE HEAVENS

zaid n. adwan

Take the Sidereal time at noon on the day of birth, and add to it the hours and minutes after noon at which you were born, or if before noon, subtract from it the interval between the birth and noon. This will give the approximate Right Ascension of the Midheaven at birth. Thus, suppose a person to be born on May 1, 1890, at 3h. 30m. p.m. in London—

The Sidereal time, noon, May 1, 1890, is 2h. 36m. 28s.

To which add time p.m. …… … 3 30 0

Acceleration at 10″ per hour … … 0 0 34

Right Ascension of Midheaven at Birth 6h. 7m. 2s.

With this Right Ascension of the Midheaven you then refer to Tables of Houses for London (see Chapter III.), and against this quantity of Sidereal Time you will find, under the column marked 10, the sign and degree which corresponds to it, namely, the 2nd of Cancer. This is put at the head of the figure, and the rest of the signs are placed around the figure in their order as shown in the Table. Only six of the Houses are given in the [Pg 37] Tables, because the opposite Houses will have the *same* degrees of the *opposite* signs on them. Thus we read against the Right Ascension 6h. 7m. 28s. the following:—

10	11	12	Ascen.	2	3

Cancer 2, Leo 8, Virgo 8, Libra 1.33, Libra 26, Scorp. 26.

This means that the 2nd degree of Cancer was on the cusp of the Tenth House (the Midheaven) at the moment of the birth, Leo 8th on the cusp of the Eleventh House, Virgo 8th on the cusp of the Twelfth, Libra 1.33 on the Ascendant or Eastern Horizon, and so of the rest. On the cusp of the Fourth House we place Capricornus 2, because the Fourth House is opposite the 10th and the sign Capricornus is opposite to Cancer. On the cusp of the Fifth House we place Aquarius 8, because the Fifth House is opposite to the Eleventh, and Aquarius is opposite to Leo. When completed we find the cusps of the Houses as follows, opposite to those in the Tables:—

4 5 6 7 8 9

Capric. 2, Aquar. 8, Pisces 8, Aries 1.33, Aries 26, Taur. 26.

It is then only necessary to place the planets in the figure, as explained in the preceding chapter, and the figure of the Heavens is complete.

To Draw a Figure of the Heavens.

Take a pair of compasses, and with a radius, of about 2½ inches, describe a circle. Within this, and with a radius of about 2 inches, describe another. With the radius of this latter mark off six equal divisions, and then[Pg 38] equally divide these so as to make twelve. Within the figure draw a small circle, concentric with the others, to represent the Earth. From the points of division already obtained draw straight lines to the centre of the figure until they touch the circle of the Earth. You then have a figure which represents the Houses of the Heavens, being a twelvefold division of the Prime Vertical. The lines extending from the outer circles to the Earth are the cusps of the Houses (see fig. Section IV., chap. 5).

The degrees of the Zodiac which are upon the cusps of the Houses, as found in the Tables opposite a given Sidereal Time, are written over the several cusps in their order between the two outer circles. Reference to the Ephemeris for May 1, 1890, shows the Sun at noon in Taurus 11 degrees 2 minutes. Three and a half hours later it will have advanced about 8 minutes in longitude, so that its position will be in Taurus 11 degrees 10 minutes. This longitude falls in the Eighth House, and we therefore place the symbol of the Sun in that division of the Heavens and place against it the figures 11.10, so that as Aries 26 is on the cusp of the Eighth and Taurus 26 on the cusp of the Ninth House, the Sun's position in Taurus 11.10 will fall between these cusps, *i.e.*, in the Eighth House. The rest of the planets are placed in the figure according to their respective longitudes.

[Pg 39]

CHAPTER III

THE TABLES OF HOUSES

The Tables of the Houses on pp. 40, 41, are calculated for the latitude of 51° 32′ North. This will serve for London and environs, and approximately for the South of England and the Midlands. Tables of Houses for other latitudes may be obtained through the booksellers, a useful set of half a dozen different latitudes being sold for one shilling.

In order to illustrate the uses to which these Tables may be put in the solution of astronomical problems, let us take the Sun's position in the horoscope for the 1st of May, 1890, and find when the Sun sets on that day on the horizon of London. The Sun is in Taurus, 11 degrees, and it will set when the opposite point of the Heavens is rising.

Find under the column marked “Ascen.” the 11th degree of Scorpio, and against it in the column marked “Sidereal Time” you will find 9h. 49m. 9s. This will be the Right Ascension of the Midheaven when the Sun sets on London. We have already seen that the Sidereal Time at noon on the 1st of May was 2h. 37m. 28s., and this, taken from the former Sidereal Time, gives about 7.12 p.m. as the time of sunset. Now in the example horoscope the birth took place at 3.30 p.m., and this time, taken from 7.12 p.m., gives 3h. 42m. from birth to sunset. If you multiply this by 15 to turn it into degrees and minutes of the Equator, you will obtain 55° 30′, which are the number of degrees which pass over the Midheaven from birth until sunset. At the rate of 1 degree for every year of life, this corresponds to 55½ years of age, when the subject of this horoscope would come under the adverse influence of the Sun opposition Ascendant, and would suffer some serious ill health of a feverish nature, incident to the throat (the part ruled by Taurus, the sign in which the Sun is situate). This is how predictions are made, but of this more anon.

[Pg 42]

If I wished to know what particular part of the Zodiac one is subject to in any particular year of life—that is to say, what part of the Zodiac is rising—I add 1 degree for every year to the Midheaven at birth and thus obtain a new Midheaven, under which, in the Tables of Houses, I find the Ascendant which rules the year. Thus in the case of one born on the 1st of May at 3.30 p.m. the 30th year comes under the Midheaven of Leo

Zaid H. adwan

2, which is 30 degrees further advanced than Cancer 2, and under Leo 2 in the 10th House I find the Ascendant to be in Libra 24.7, which is the Ascendant governing that year of life. The meaning and importance of these calculations will appear at a later stage of this exposition.

When a degree is on the Midheaven or the 10th House it is said to "culminate," and when on the horizon Eastward it is said to "ascend."

The Midheaven is often called the "M.C." (Medium Coeli), and the opposite point is called the "I.C." (Imaum Coeli). They are the points of the Ecliptic which cut through the meridian of a place at any given time.

[Pg 43]

CHAPTER IV

PLANETARY TRANSITS

In order that prognostications made from the horoscope of birth may be pointed as to time it is necessary to know the positions of the planets for several years in advance. Such calculations are easily effected by a knowledge of the periods of the planets—that is to say, the times in which they return to the same positions about the same time of the year. Thus Uranus returns to its place after a period of 84 years, Saturn does so after 59 years, Jupiter in 83 years, Mars in 79 years, in all cases almost to the day. Mercury also returns in 79 years. But as very few people possess records of the planets' places for these long periods, the following table of the longitudes of the planets for the next 12 years has been prepared. The positions are given for the 1st of each month, and the longitudes held by the planets are given in even degrees.

zaid.n.adwan

These tables are very useful in tracing the transits that occur in connection with the horoscope for the year. Thus we have found that by adding the number of degrees corresponding to the age of a person to the Midheaven at birth, we obtain the Progressed Midheaven,[Pg 44] and in the Tables of Houses we may also find the corresponding Progressed Ascendant. By adding the same number of degrees to the place of the Sun at birth we obtain also the Progressed position of the Sun.

Now a transit of one of the major planets over any of these points, namely, the Midheaven or Ascendant at birth, the Sun or Moon at birth, the Midheaven, Ascendant, and Sun in the progress, will produce marked effects on the fortunes and health of the Subject, corresponding to the nature of the planet which makes the transit.

Thus we have seen that the Midheaven at the birth on the 1st of May, 1890, at 3.30 p.m., was Cancer 2 degrees, and the Ascendant Libra 2. Referring to the Tables, we find that in 1905 Saturn will form the opposition of the Midheaven in Capricornus 2 in February, July, and November, so that these will be periods of reversal, sudden and unexpected complications and changes. Also the Sun at birth being in Taurus 11 receives the transit of Jupiter in April, 1905, so that this month will be productive of some amelioration of evils, or direct benefits.

When two or more planets concur in a transit of any of the Significators the results are so much the more forcible and effective.

[Pg 47]

CHAPTER V

TABLE OF ECLIPSES

zain.adwan

The following Table of the Eclipses that will take place during the next twelve years will be found of considerable use in forecasting the effects which will follow, not only on the individual, but also on nations and countries. Thus should any of the Eclipses fall on the place of a Significator in a horoscope, it will have the most sinister effect upon the life and fortunes. Certain countries are ruled by certain signs, a matter which has been determined from observation ever since the days of Claudius Ptolemy A.D. 130, and Eclipses falling therein have the effect of disturbing the government of those countries, producing effects of the worst kind. (See Sect. IV., chap. 6).

[Pg 48]

TABLE OF ECLIPSES, 1905–1916.

1905.—18th February, Moon eclipsed in Leo 29.
5th March, Sun eclipsed in Pisces 14.
14th August, Moon eclipsed in Aquarius 21.
30th August, Sun eclipsed in Virgo 6.

1906.—8th February, Moon eclipsed in Leo 19.
22nd February, Sun eclipsed in Pisces 3.
20th July, Sun eclipsed in Cancer 27.
3rd August, Moon eclipsed in Aquarius 10.
18th August, Sun eclipsed in Leo 24.
14th January, Sun eclipsed in Capricornus 23.

1907.—28th January, Moon eclipsed in Aquarius 7.
9th July, Sun eclipsed in Cancer 16.
23rd July, Moon eclipsed in Leo 4.

zaid nadwan

1908.—3rd January, Sun eclipsed in Capricornus 12.
28th August, Sun eclipsed in Virgo 4.
7th December, Moon eclipsed in Gemini 14.
22nd December, Sun eclipsed in Sagittarius 30.

1909.—3rd June, Moon eclipsed in Sagittarius 12.
17th June, Sun eclipsed in Gemini 25.
26th November, Moon eclipsed in Gemini 3.
12th December, Sun eclipsed in Sagittarius 19.

1910.—9th May, Sun eclipsed in Taurus 18.
22nd May, Moon eclipsed in Sagittarius 0.
1st November, Sun eclipsed in Scorpio 7.
15th November, Moon eclipsed in Taurus 21.

1911.—28th April, Sun eclipsed in Taurus 7.
20th October, Sun eclipsed in Libra 26.

1912.—1st April, Moon eclipsed in Libra 11.
16th April, Sun eclipsed in Aries 25.
25th September, Moon eclipsed in Aries 1.
10th October, Sun eclipsed in Libra 16.

1913.—21st March, Moon eclipsed in Virgo 30.
5th April, Sun eclipsed in Aries 15.
30th August, Sun eclipsed in Virgo 7.
14th September, Moon eclipsed in Virgo 20.
28th September, Sun eclipsed in Libra 4.

1914.—24th February, Sun eclipsed in Pisces 5.
9th March, Moon eclipsed in Virgo 18.

zain adwan

21st August, Moon eclipsed in Aquarius 27.

3rd September, Sun eclipsed in Virgo 10.

1915.—13th February, Sun eclipsed in Aquarius 24.

9th August, Sun eclipsed in Leo 16.

1916.—18th January, Moon eclipsed in Cancer 27.

3rd February, Sun eclipsed in Aquarius 13.

14th July, Moon eclipsed in Capricornus 21.

29th July, Sun eclipsed in Leo 5.

[Pg 49]

In illustration of the effects of Eclipses in the horoscope of birth, we may refer to the horoscope of His Majesty King Edward VII., wherein we find the sun situated in the 17th degree of the sign Scorpio, which rules the excretory system. In May, 1902, there was an Eclipse of the Sun in opposition to this position, and within five weeks of the Eclipse the King was struck down with appendicitis on the eve of the Coronation Ceremony. This was foretold in many of the journals devoted to the exposition of Astrology, and in Moore's Almanac for the month of June, 1902, the hieroglyphic clearly pointed to the danger that beset the august Sovereign. Indeed, I was able to say with perfect assurance that the Coronation would not take place on the date appointed, and gave the exact date at which the King would be struck down with what I conceived to be a mortal illness. But fortunately at that time the Moon was conjoined to Jupiter in the progress and this saved the life. The Moon was then setting in the horoscope of birth, according to the measure of time already given, namely,[Pg 50] one degree of Right Ascension for one year of life, and Saturn was on the Midheaven.

The Eclipse of June 6, 1853, was in the Midheaven at Cumana on the Spanish Main and in five weeks there followed a terrible earthquake which killed 4,000 people and destroyed all the property. In May, 1901, there was an Eclipse on the 8th of May which

fell in the meridian of St. Pierre, Martinique, and the same day there was a fearful devastation of the place by the eruption of Mont Pelée.

Instances might be multiplied to show that the effects of Eclipses are of the most striking and effective nature.

[Pg 51]

SECTION III

HOW TO READ THE HOROSCOPE

CHAPTER I

THE PLANETS IN THE HOUSES

It is impossible to categorically state the effects which are due to the positions of the planets in the several Houses, because very much depends upon the signs they are in and the aspects they have from other planets.

The means of judging the effects is very simple, when once the natures of the planets and the dominion of the several Houses have been thoroughly digested. Thus, it is first necessary to see in what House a planet is situated. Then consider the nature of the planet in the following concrete manner:

Zaid n. adwan

Neptune means chaos, confusion, deception.
Uranus, eccentricity, originality, estrangement.
Saturn, privation, hindrance, denial.
Jupiter, affluence, fruitfulness, increase.
Sun, dignities, honours.
Mars, excess, impulse, quarrels.
Venus, peace, happiness, agreement[Pg 52] Mercury, commerce, versatility, adaptability.
Moon, changes, publicity.

Now look to the things that are governed by the House in which any particular planet is situated at the moment of birth (Sect. I., chap. iii.).

Suppose Saturn to be found in the 11th House. Saturn is "privation" and the 11th House is the domain of "Friends." Hence a paucity of friends, or such as there may be are evil or unfortunate to the subject. Jupiter in the 2nd House, in the same manner, would signify "increase" of "money and possessions." Mars in the 7th would indicate "quarrels" with "partners"; and so on. Each planet reflects its own nature upon the affairs governed by the House in which it is found at the moment of birth.

It will not infrequently happen, however, that there are more than one planet in the same House. Suppose two planets to occupy the same House. In such case one may be good (Jupiter), and the other evil (Mars). It is then necessary to take first that which first comes to the horizon or Midheaven, that is to say, the one which is in the earlier part of the House, and next that which follows. Thus Saturn followed by Jupiter in the 11th House, would signify misfortune by means of advisers and friends, followed at a later period in the life by some great good through the same source. The degrees which separate the planets will indicate the years which elapse between these changes of fortune. Similarly if there be more than two planets in the same House; in such cases

you may safely predict many changes in that department of life which the House is said to rule.

[Pg 53]

But the fact of a planet being in a House is not of itself sufficient evidence from which to make a judgment. The aspects which that planet has must also be considered, for in this matter Saturn when throwing a good aspect to any of the Significators—the Sun, Moon, Ascendant or Midheaven, and well aspected by other planets, is to be preferred to Jupiter when the latter is badly placed and aspected; for Jupiter has his own ill effects, and Saturn has his good influences. Jupiter is only a benefic when acting by conjunction or good aspect with another planet, and Saturn is only a malefic when acting by conjunction or evil aspect.

These things being duly considered, it is possible to arrive, with even brief experience, at the results that are signified by the planets in the several Houses.

[Pg 54]

CHAPTER II

THE CONSTITUTION

The Sun is the chief significator of the constitution, and the aspects he holds to the other planets are to be considered. Thus if he be found in good aspect, or at least not in evil aspect, to the other planets, the constitution may be judged as sound.

When, however, the Sun is afflicted by some planets and assisted by others, there will be only a moderate constitution, and judgment has to be made as to which influence predominates, the good or evil. When the afflicting planets are angular—that is to say,

zaid n. adwan

in the 1st, 4th, 7th, or 10th Houses—the congenital or hereditary tendency to organic disease is by that circumstance so much the stronger. But when the assisting planets are angular, the predisposition to disease is considerably mitigated, and in most cases entirely overcome.

The predisposition of the body to affections of a constitutional nature is to be judged from the prevalence of evil aspects to the Sun, and the parts of the body liable to be affected are judged from the Signs which are occupied by the afflicting bodies.

The various affections due to the several planets have already been cited (Sect. I., chap. i.). The Signs are grouped for purposes of pathological study as follows:—

[Pg 55]

The Movable Signs—Aries, Cancer, Libra, and Capricornus—have relation to the head, stomach, skin, kidneys, liver, and spine.

The Fixed Signs—Taurus, Leo, Scorpio, and Aquarius—are related to the throat, heart, blood, and excretory system.

The Common Signs—Gemini, Virgo, Sagittarius, and Pisces—are related to the lungs, bowels, and nervous system.

It will also be advisable to read Sect. I., chap. ii., in order to determine the special points liable to affections, the nature of the affection being judged solely by the planet which casts the malefic aspect to the Sun.

When the Sun is found to be afflicted by several planets, and at the same time there is no assistance from the good aspects or conjunctions of other bodies, then the constitution is deemed faulty and liable to early disruption. But when there are several planets afflicting and at the same time some benefic influences from others, it is probable that there will be prolonged disease and physical weakness, though life will continue.

Death in infancy occurs when the malefic planets are immediately rising or culminating at the birth in evil aspect to the luminary which at the time may be above the horizon. Also when there are malefic planets immediately setting or passing the nadir, in evil aspect to the luminary below the horizon. But when there are mitigating influences from the good aspects of the benefic planets, or the luminaries, the malefic planets will not induce death, but there will be great difficulty in rearing.

[Pg 56]

CHAPTER III

HEALTH AND SICKNESS

The aspects of the moon are the chief consideration in the matter of sickness. If the Moon be found to be afflicted by the evil aspects of several planets, and no assistance be given by the good aspects of others, then the health will be precarious and frequent spells of illness will result. The Moon being well aspected and not in any way afflicted, shows that the health will be well established, and that there will be immunity from sickness of all sorts.

The considerations necessary to be made in this matter are similar to those which have been cited in regard to the Sun and the constitution, except that we substitute the Moon for the Sun. For, whereas the Sun governs the vital power in man, the Moon governs the functional powers, and whereas the Sun denotes those affections which are congenital or hereditary, the Moon denotes such as are brought about by causes after birth. Similarly, the Sun denotes affections which are incidental to the body, while the Moon denotes such as are accidental thereto.

Zain Adwan

[Pg 57]

These points being borne in mind, they may be memorised at sight:—

SUN.	MOON.
Organic.	Functional.
Hereditary.	Acquired.
Incidental.	Accidental.

But it should be observed that the constitution may be strong and the health may be at the same time very bad, or, on the other hand, the health may be good and the constitution may be weak. In the first case, there would be a long life of considerable suffering from ill-health; and in the second case, there would be little or no ill-health for some considerable time, but the constitution would give way and the vital powers become depleted by the first serious illness that occurred.

Only when the Sun and Moon are both unafflicted by evil aspects or conjunctions, the health and constitution are both good, and there is every indication of a robust and vigorous life reaching to a ripe old age.

When the Sun and Moon are both heavily afflicted, and there is no assistance given by good aspects, there is every probability of death in infancy, or before reaching maturity.

For reasons which are allied to the connection existing between the constitution and the health, the good aspect of the Moon to the Sun at birth is an excellent augury, for it indicates co-ordination between the organic and functional. Where this co-ordination exists there is always considerable power of recuperation, so that illness is easily overcome and the balance of power restored in the system.

[Pg 58]

Malefic planets rising and afflicting either the Sun or Moon indicate prolonged ill-health, and most frequently some permanent hurt to the body.

When predisposition to illness is shown in the horoscope, the particular affection can be determined by the Sign which the afflicting planets hold. Thus if Saturn afflict the Moon from Aries, you will judge some hurts and obstructions in the head, chills and colds, influenza, coryza, &c. Similarly Mars in Leo would indicate functional defects of the heart due to accelerated action and overstrain, such as result from fevers.

A good aspect of the planets Jupiter and Venus is of material help in counteracting the influence of malefic aspects or evil positions.

Thus it will be seen that the health may be judged entirely apart from the constitution, the planets which are in aspect to the Moon being of first consideration, and next those which may be rising at the time of birth.

[Pg 59]

CHAPTER IV

HOW TO READ CHARACTER AND DISPOSITION

Ptolemy says: “Mercury is the ruler of the rational soul, the Moon of the animal soul.” By this he would mean, no doubt, that Mercury has relation to the faculty of the mind, while the Moon is related to brain function. There are certain attributes of the mind which are distinctive of the human being, and certain other qualities which are common to man and the lower animals. These latter are under the dominion of the Moon, while Mercury has chief signification of the rational faculties.

zaid n. adwan

The position and aspects of the Moon and Mercury are therefore to be considered in making judgment of the mental endowments and disposition of the subject.

Planets that are in conjunction or aspect to either the Moon or Mercury will impress their nature strongly on the character and disposition. The natures of the planets have already been recited (Sect. I., chap. i.), and it is therefore only necessary to consider further, in this connection, the nature of the aspect that is thrown to the Mental Significators by the other bodies. Thus the Sun being in trine to the Moon will give a proper degree[Pg 60] of independence and dignity, while the square aspect or opposition of the Sun would indicate an excess of pride, harmful to the subject in his ordinary relationships. In the same manner, the good aspect of Jupiter would show benevolence and regulated philanthropy, while the opposition or other evil aspect of the same body would indicate extravagance and ostentatious display of charity.

The good and bad aspects of the planets may be summed up in a few lines as follows:—

In Good Aspect.	In Evil Aspect.
Neptune—Genius, inspiration.	Insanity, obsession.
Uranus—Originality, invention.	Obstinacy, eccentricity.
Saturn—Steadfastness, fidelity.	Deceitfulness, suspicion.
Jupiter—Benevolence, joviality.	Ostentation, profligacy.
Mars—Energy, executiveness.	Impulse, destructiveness.
Sun—Dignity, independence.	Vanity, egotism.

zaid n. adwan

Venus—Affability, art.	Self-indulgence, disorderliness.
Mercury—Alertness, ingenuity.	Inquisitiveness, meddling.
Moon—Grace, idealism.	Inconstancy, awkwardness.

The general trend of the disposition and habit of mind is judged by the position of the majority of the planets, according to the "Constitution" of the Signs they occupy. Thus, the majority of the planets being in—

Cardinal or Movable Signs indicates executive ability, business aptitude, pioneer spirit, ambition, capability to cut out a line in life for oneself, and to make headway against difficulties. Such persons are usually the foremost in their particular sphere of life, and are always found in the most progressive movements, reforms, &c.

Fixed Signs—Stability, patience, endurance, method, caution, and diplomacy. Such persons are apt to[Pg 61] become the originators of schools of thought, policies, and schemes. They have fixity of purpose, determination, independence, and pivotal stability. They sit still and the world revolves around them.

Flexed or Common Signs—Versatility, flexibility, suavity, adaptability, and lack of originality. Such people usually have too many irons in the fire, and take in hand more than they can bring to satisfactory conclusion. This is due to their versatility. They have a superficial knowledge of many things, but lack the persistence to bring that knowledge to practical effect. At the same time their adaptability is the occasion of many successes in life, and their agreeableness, sympathy, and suavity create many friends for them.

In the Wheel of Life the cardinal signs denote the rim or tyre which is ever on the move, having the greatest acceleration. The Common Signs represent the spokes of the wheel, uniting the tyre to the nave, and in that sense representing the power of adaptability.

The Fixed Signs represent the nave, which remains quiescent and still, being useful by that pivotal stability and apparent non-entity.

Thus, while the Sign-groupings of the planets are useful in giving the keynote of the nature and disposition, the particular faculties and characteristics are to be judged only from the aspects of the planets to the Moon and Mercury. Further, it will be noted that those planets which occupy the 3rd and 9th Houses, and those also which are just rising at the moment of birth, will strongly impress themselves on the nature, apart from any aspects they may hold to the Mental Rulers. This is on account of the natural relationship of those Houses to the mind and its means of expression.

[Pg 62]

Due attention must be paid to the position and aspects of those planets which are in aspect to the Mental Rulers, for if they be badly placed, in uncongenial signs, and themselves badly aspected by other planets, they will not act with the same directness and force as they otherwise would do.

It is of course admitted, in all astrological inquiries, that the effects of heredity, training and association count for something. A man who is generated from a vitiated parentage, badly nourished and imperfectly trained, cannot be expected, even with the best aspects, to manifest the highest faculties in their fullest or most perfect expressions. I have not the slightest doubt that many a clodpole was born under similar aspects to those which obtained at the birth of Shakespeare, Raphael, Newton, or Cæsar. I am not dismayed. *Non gli astri muovono solamente per Roma!* Who shall tell the tale of the world's starved, neglected, and submerged genius? We are doing the right thing, at all events, in keeping the school-door wide open.

But to continue. The inspirational and ardent temperament is indicated by the majority of planets being in Fiery signs. The mental or intellectual temperament is shown by the majority in Aerial signs. The psychic or emotional temperament by the majority in

Watery signs, and the practical or sordid temperament by the majority being in Earthy signs.

The rising sign at birth often impresses itself strongly on the mind of the Subject, and its characteristics are those which belong to the planet which governs it, and the "elemental" nature of the sign itself.

Thus you have the chief keys to the estimate of[Pg 63] character in the individual, and when once the student is convinced by experience of the paramount reliability of this method of character-delineation, its uses will need no special pointing.

Mental and Brain Disorders.

When either the Moon or Mercury is afflicted by the malefic planets, that is to say, when Neptune, Uranus, Saturn, or Mars are in conjunction or evil aspect with the mental Significators, and there be no relieving aspect from the benefic planets, Jupiter, Venus, or the Sun, then there is every predisposition to affections of the brain and nervous system. This is the more to be feared when the Moon or Mercury is afflicted in the flexed or common signs. This observation has been scientifically established by Mr. A. G. Trent, in his little work entitled "The Soul and the Stars," to which the student is referred for a mass of statistical evidence.

[Pg 64]

CHAPTER V

FINANCIAL PROSPECTS

zaid n. adwan

Look to the planets which are in the 2nd House, and the aspects to them. If any planet be therein, and well aspected by others, the financial condition will be competent. If a benefic (Jupiter or Venus) be therein, and free from evil aspects, the same effect will accrue. But if the benefic in the 2nd should have good aspects from other planets, then there will be considerable wealth.

Any planet in the 2nd House, badly aspected, will produce difficulty in acquiring money, and if it be a malefic planet which occupies the 2nd House under these conditions, there will be times of stress and even poverty.

Continual hardship and poverty is shown by malefic planets in the 2nd House, in evil aspect to the Moon or Sun; while at the same time the planets in the 2nd House will be severely afflicted by others.

Saturn in the Midheaven afflicting the Sun or Moon is an indication of reversal of fortune, and such persons usually attain considerable position in the world and are then depleted of everything.

Jupiter or Venus in the 10th House, and near the[Pg 65] meridian, are signs of good fortune and success in life, and the same results are due to their rising at birth.

In a general manner the aspects to the Moon in a male horoscope or the Sun in a female horoscope should be consulted, and the planets in good aspect thereto will show the means of good fortune, while those in evil aspect will indicate the sources of loss and hurt, according to the Houses the afflicting or assisting planets occupy. Thus Jupiter in good aspect to the Moon from the 11th House shows gain by friends, advisers, and co-operative measures, because the 11th House rules these relationships and Jupiter is the index of increase. Similarly, Uranus in the 7th House would show gain by the marriage partner if in good aspect to the Moon, or loss thereby if in evil aspect.

Mars in the 2nd House shows good earning capacity, because Mars is an ambitious and industrious planet (*i.e.*, it produces such effects in the person), and the 2nd House is the

Zaid Adwan

domain of finance. But at the same time it shows extravagance and inability to save money, for Mars is impulsive and lacking thrift.

The 6th House well occupied shows faithful and advantageous servants and employés, such as will augment the fortunes and do good work for the Subject.

Neptune in the 2nd shows complications and an involved state of finance, and frequently it shows loss by fraud and imposition; though in good aspect to other planets it shows gain by such nefarious means. Uranus indicates many ups and downs of fortune, sudden and unexpected rises and falls.

Thus each planet is judged according to its nature and the aspect it throws to the Moon or Sun, while the[Pg 66] planets in the 2nd House are judged by their own natures and the aspects which they receive.

Inheritance is shown by a benefic planet in the 5th or 11th House in good aspect to Saturn; but indirect inheritance can be the result of Saturn in good aspect to Jupiter from any part of the figure.

Legacies are shown by good planets, or planets well aspected, in the 8th House; or by Jupiter in good aspect to Uranus from any part of the heavens.

Gain by marriage is shown by benefic planets in the 8th House, because the 8th is 2nd from the 7th, and the 7th House rules over the partner.

The potential of each horoscope is capable of being increased by due attention to the sources of gain, as shown by the position and aspects of the planets in various parts of the heavens; but chiefly by associating oneself with persons whose horoscopes are in harmony with one's own. Thus it happens that individuals are lifted to position and affluence through their association with persons whose horoscopes are in sympathy with theirs. (See Chap. XI. of this Section.)

The Sun and Moon being in good aspect to one another will prevent disaster, or will always provide a means of restoration of fortunes, because it is an index of general good

fortune and continual support. Such persons as have this aspect in their horoscopes need never fear misfortune, for if they should fall into disasters in one place, they will always turn up in another with a complete adjustment of their position. But when the Sun and Moon are in evil aspect, and particularly when the malefic planets are in elevation in the heavens, continual misfortune dogs the footsteps, and though there[Pg 67] be spells of good fortune, they are brief and attended with troubles.

The benefic planets, Jupiter, Venus, and Sun, being well elevated in the heavens, that is to say, in the 10th or 11th Houses, it is a sign of preponderating good fortune. But when the malefics are in elevation the reverse results happen.

The Line of Least Resistance.

It is a law in Nature that the line of least resistance is that of greatest progress. The lightning flash does not come straight to earth, but zigzag by the line of least resistance. The great rivers do not come by a direct course to the ocean, but by many turns and backward reaches, because they follow the path of least resistance. When one comes to take account of the years of human life that are spent in the vain endeavour to achieve the impossible, the lessons of Nature are worth reciting. But what is impossible to one man is facile to another, and the greatest economy of effort is therefore to be secured by proper regard to suitability of occupation and direction of effort.

The principles of Astrology enable us to determine the line of action which at all times will be the most fruitful of results, and in the matter of money-making the matter is decided in the following manner: That planet which has a trine or sextile aspect of the Moon, and is at the same time elevated above the malefic planets, especially if it be itself assisted by the good aspects of other planets, receives first consideration. The House it is in will indicate the source of benefit, but the Sign it is in will show the means through which it will come. Thus if[Pg 68] Uranus should be in the Midheaven, in trine aspect to the Moon, and itself receiving a good aspect from either the Sun, Jupiter, or

Venus, it will indicate gain through governmental bodies, authorities, and persons of high rank. If Uranus should be in the sign Cancer, it would point to matters associated with the ocean, marine affairs, or those in which water is the element in chief employ; as in marine engineering, shipping, dock building, &c. But if Uranus had been in the 11th House, and in the sign Scorpio, then the source of gain would be by means of companies, syndicates, and associations of a collective nature, and the sign Scorpio would show it to be connected with naval defence (because Scorpio is a martial and watery sign) or the utilisation of waste materials, inflammable oils, &c., or by systems of drainage, which represent the excretory system of a town. By looking chiefly to the nature of the planet concerned, and that of the sign it occupies, a good artist will readily describe the particular line which is to be pursued.

But here, as in every other matter upon which judgment is made, attention must be paid to the character and disposition of the Subject, his aptitudes and qualifications, for it is obviously of little use recommending literature or the law to one whose sole capabilities lie in unintellectual directions. Natural aptitude, supplemented by the necessary training, are the first considerations, for without these success in any direction is but ill assured.

[Pg 69]

CHAPTER VI

THE POSITION IN LIFE

This is to be judged from the position of the majority of the planets, but principally from the Midheaven, the planets therein and its aspects. Thus, if you find the majority of the

zaid n. adwan

planets rising, that is to say, in the 10th, 11th, 12th, 1st, 2nd, and 3rd Houses the Subject will be a candidate for responsibility, ambitious of honours and position, and generally independent. If these or the majority of them be well aspected he will become a man of position, employing others; or, if a woman, will hold an important position in her sphere of life, and be esteemed in the social world.

If the degree on the Midheaven receives good aspects from the major planets, the position will be honourable and secure.

Venus or Jupiter, or the Sun well aspected, in the Midheaven, denotes a superior position, honours, and distinction. The same will result if these be rising.

When the majority of the planets are above the horizon, even though they be not rising, the Subject will have responsibilities thrust upon him, even though he should not desire them. If the majority of these[Pg 70] planets be well aspected, he will acquit himself creditably and attain to honours.

It is always fortunate for the position that there should be planets exactly on the cusps of either the 2nd, 3rd, 6th, 8th, or 12th Houses, for then there will be every opportunity of securing fame and advancement in life.

But when any of the malefic planets are found exactly on or nearest to the meridian, whether above or below the horizon, there will be loss of position, reversal, a sinister fame, or disgrace.

The 10th House represents the fame and honour of a person, and the 4th House represents the end of life and that which militates against the fame and honour. Therefore when there are good planets in these places, the Subject will meet with rewards and honours commensurate with his efforts; but when evil planets occupy the meridian, he will at best sustain his position in life with great difficulty.

It is futile for any one to suppose that the position of a benefic planet in the meridian of the horoscope will bring him to fame and elevate him in the world irrespective of his

zain.adwan

own endeavours. The planets operate on human affairs in terms of human thought and action, and that by fixed laws; never adventitiously. That "the Gods help those who help themselves" to the extent that natural laws permit, is a truth which astrology fully provides for. Fitness and fortune are as cause and effect to one another in respect of planetary action in human life.

Many planets in cardinal signs will dispose a man to seek fame, and when the Midheaven of the horoscope is well aspected or there be fortunate planets therein, he[Pg 71] will attain it. Cardinal signs on the angles of the horoscope (the meridian and horizon), produce fame outlasting death. The same if either of the luminaries be exactly on the equinoxes.

Venus in the Midheaven gives social elevation and lifts a person above the sphere of birth. Good planets in the 11th show patronage.

But when the luminaries are heavily afflicted there will be an inconstant fortune and many reverses, so that position gained will be lost again.

Most of the planets under the horizon shows success and position in the latter part of life, while if they be between the 4th and 7th cusps, there will be advantages after marriage, or by means of partnerships.

In judging of the means by which the position will be sustained, respect must be had to the positions of those planets which are in good aspect to the Midheaven, or to benefic planets in the Midheaven, and if none be so situated, then those which hold benefic aspect to either the Sun or Moon at birth must be taken, and judgment made according to the nature of the planet and the sign it occupies. Preference should always be given to that planet which has the strongest aspect for good. Thus if two planets were in trine, that which is in elevation should be preferred, especially if it be strengthened by the good aspects of other planets.

Zain Adwan

[Pg 72]

CHAPTER VII

THE CHOICE OF OCCUPATION

The enormous waste of force and time entailed by the experimental trip upon which most young men embark at the outset of their career in life, might be greatly reduced by a proper knowledge of individual aptitude in relation to circumstances. The average boy cannot readily make up his mind as to what occupation he will follow, because he does not know either enough of his own powers or of the world in which he is called upon to use them. Parents are in the same difficulty. They must needs wait to see how a boy will shape out. They study his inclinations to the best of their ability, but without coming to a definite conclusion any sooner than the boy himself. Given a fair education, such as may fit him for almost anything, but which specialises him for nothing in particular, he is put to some desk or bench and there left to his own resources. By a fortunate chance, he may find himself suited to his post. More frequently he is several years in finding out that he has missed his vocation, that his inclinations and his work are not in accord, that he has misapplied his energies for some time, and that he has made a false start. Fortu[Pg 73]nately circumstanced at birth he may have been equipped by higher education for some distinctive profession, to which he gains access after the payment of large fees or premiums. The man has a strong dramatic faculty and the stage claims him after all. Here is both waste of time and money. Astrology, as a reliable key to character and inclination, deserves some recognition on the grounds of social economy.

The inclinations of the Subject are judged from the position of the majority of the planets, for if they should be found in the aerial signs, Gemini, Libra, or Aquarius, the

inclination will be towards mental occupations, especially science and literature. In fiery signs there is a predisposition to a more robust and active life, such as is afforded by military service, travelling, prospecting, exploring, &c. In earthy signs the aptitude lies in the direction of agriculture, experimental science, surveying, dealing in real estate, broking, &c. In watery signs there is special inclination to pursuits connected with the water, such as sailors, watermen, and others; but frequently to other occupation in which fluids are predominant, such as publicans, wine and spirit merchants, chemists, and oil merchants.

Each sign has its special tendency, and the exact occupation can often be decided thereby, when regard is had to the planet in closest aspect to the Sun or Moon and the sign it occupies. Thus Aries denotes soldiers and pioneers of movements; Taurus shows dealers in real estate, house agents and brokers; Gemini, literary men and writers of all sorts; Cancer, sailors and publicans; Leo, actors and artists; Virgo, clothes dealers and sellers of confectionery and bread; Libra, valuers, assayers,[Pg 74] money-changers, and pawnbrokers; Scorpio, naval sailors, chemists, dealers in oils and spirits; Sagittarius, explorers, divines, lawyers; Capricornus, political agents and ministers of the State; Aquarius, electricians, company promoters, syndics, and scientific researchers; Pisces, dealers in fish and sea produce, warders, and those connected with places of confinement, such as prisons and hospitals.

Taking, therefore, the dominant planet and the signs that hold the majority of the planets, the line along which the Subject will make the most progress in the world and acquit himself most successfully, may be readily determined.

No person will make a good soldier who has not Mars as a dominant planet, nor will he succeed with the public if the Moon be not elevated and well aspected, nor become a successful artist, musician, or poet if Venus be not conspicuous in the horoscope.

Generally the inclination is derived from a consideration of the dominant planet, and the degree of success attendant upon the occupation is judged from the aspect which

zain.adwan

that planet throws to the Sun or Moon, and there can be no great advantage from following an inclination which does not promise some measure of success, as is the case when the dominant planet is in evil aspect to the luminaries. Thus it happens that some men follow unprofitable callings, their judgment being dominated by an inclination adverse to their natural welfare. Yet never was good work done in the world without a strong inclination and considerable enthusiasm, and Heaven makes its own slaves, its martyrs, and its scapegoats. And always, the following of an inclination means the[Pg 75] sacrifice of some of the benefits of life. "Take what thou wilt, but pay the price!" is the Divine mandate, according to Emerson.

But unquestionably, the science which enables a man to choose the line of least resistance, which prevents a youth of intellectual tendencies from wasting the best years of his life in drudgery at the desk or bench, is worth a little study. "Hitch your waggon to a star," is good advice if only we hitch it to the right one.

[Pg 76]

CHAPTER VIII

MARRIAGE CIRCUMSTANCES

The question as to how, when, and where marriage will take place is an all-absorbing one to the majority of men and women, and no less important than interesting. Astrology has made it possible to answer these questions categorically and with particular precision and verity.

The conditions of connubial life are judged (in a male horoscope) from the condition of the Moon and Venus, and (in a female horoscope) from that of the Sun and Mars. The

zaid n. adwan

planet to which the luminary first forms an aspect after birth (that which it "applies" to) denotes the marriage partner. If the aspect be good there will be agreement and the choice of a partner will be fortunate. But if the aspect be evil, there will be trouble after marriage. The nature of the planet to which the luminary forms its aspect after birth ought also to be considered, for if it be that the luminary applies by a good aspect to a benefic planet, or to one that is well-placed and aspected, then there will be considerable happiness and fortune in marriage. On the other hand, if both the aspect and the planet be evil—as if the Moon were applying to the[Pg 77] opposition of Saturn or Uranus or Mars—then the fate in marriage will be extremely unhappy and disagreements will be frequent and even permanent.

When the aspect and the nature of the planet are at variance, as when the Moon has a good aspect to Saturn, or a bad aspect to Jupiter, there will be a mingled fortune of good and ill in marriage. There is no better sign of happiness and harmony in marriage than a good aspect between the Sun and Moon.

Moreover, it may happen that the Moon applies by good aspect to a planet after birth, and that there is at the same time a malefic body in the 7th House. This indicates that there will be agreement in the connubial life, but that bereavement will soon follow.

When the Moon applies to Neptune there will be some peculiarity or touch of genius in the partner, according as Neptune may be aspected. Uranus shows eccentricity and sometimes wilfulness. Saturn shows steadiness, industry; or jealousy and coldness. Jupiter indicates a good nature, bountiful and honest, but may be given to excess and extravagance. Mars induces industry and practicality, but it gives a strong temper and considerable independence. The Sun shows dignity and loyalty, but may indicate ostentation and foolish pride. Venus denotes peacefulness and a genial, refined nature, but its perversion brings indifference, neglect and disorderliness. Mercury denotes an active and energetic nature, but may produce a busybody and meddler.

Zaid H. adwan

Everything depends on the aspect which the significant luminary throws to the planet it applies to, for if the aspect be good it will indicate the better qualities of that planet; but if evil, then there is frequently the unfortu[Pg 78]nate consequence of choosing a partner in whom the perverted qualities of the planet are predominant.

Good planets in the 7th House indicate a good partner, but when at the same time the aspect of the luminary is evil, it will denote a good marriage, followed by bereavement.

Marriage to a widow (or widower) occurs when Mars and Saturn are the planets concerned in the indications, as if Mars be in the 7th House and in aspect to Saturn, or if the Moon apply to Mars when aspected by Saturn, or when one of them is in the 5th House and the other in the 7th.

Love affairs before marriage are indicated by the 5th House, the planets therein and their aspects, and in a general sense by Venus in a male horoscope and Mars in a female horoscope.

Thus if Venus (or Mars) be afflicted by Saturn or Uranus there will be disappointment in the early affections. Uranus in aspect to Venus gives romantic attachments and much influence over the other sex. Neptune in aspect shows idealism, and when afflicting Venus it produces chaos and entanglement, danger of seduction. Mars afflicting Venus gives ardour and impulse.

More than one Marriage

is indicated when the luminary is in aspect to more than one planet in a double-bodied sign, *e.g.*, Gemini, Sagittarius, or Pisces. Or, if the luminary itself be in a double sign and in aspect to any planet other than one which may be in the 7th House. Also a double sign being on the cusp of the 7th House, and the luminary in a fruitful[Pg 79] sign, Cancer, Scorpio, or Pisces, or in aspect to planets in those signs. All these are signs of more than one marriage during life.

Signs of separation or divorce are as follows: The luminary applying to the ill aspect of a malefic planet, Venus afflicted, and Uranus in the 7th House or afflicting the Moon or Venus. In female horoscopes change the Significators, taking the Sun and Mars instead of the Moon and Venus, and judge the same.

Where more than one marriage is shown, the ruler of the 7th House denotes the first partner, and the planet ruling the sign it occupies is called its "dispositor" or "displacer." This dispositor represents the second partner.

The planet to which the significant luminary applies is that which is taken to describe the partner, according to the sign it is in. But if this planet be retrograde, i.e., going backwards in the zodiac by apparent motion, then it only represents an attachment which will be broken off. Its dispositor then becomes the significator of the partner. But the ruler of the 7th House is taken for the condition and fortunes of the partner, and if it be afflicted or badly placed and weak in the horoscope, then the marriage will be ill-assorted, unfortunate, and full of dissatisfaction. The contrary is the case when the significant planet is well placed and aspected.

The place or circumstances under which the partner will be met may be known from the sign and house occupied by the planet to which the luminary first applies after birth. Thus if it be in the 11th House, the partner will be met among friends, at the house of a friend, or introduced by a friend. If in the 3rd House, then on a[Pg 80] short journey or in correspondence; in the 5th, at a place of amusement; in the 10th, in the course of business; and so on, judgment being made according to the places and circumstances ruled by the House occupied by the planet.

[Pg 81]

CHAPTER IX

INDICATIONS OF PROGENY

The 5th House, the planets therein and the position and aspects of the Moon, have to be considered in this matter.

If the 5th House be occupied by benefic planets, or planets well aspected by others, then the progeny will be a source of satisfaction and credit to the Subject, and will be reared to maturity. But the contrary is the case when the 5th House is occupied by malefic planets and such as may be heavily afflicted.

The Moon represents the tendency in the male and the capacity in the female, and when well aspected, or free from evil aspects and well placed, then there will be good fortune in connection with the progeny.

When Uranus afflicts a planet in the 5th House, there will be some premature births, and generally it will be observed that when planets are opposed from the 11th and 5th Houses, or malefic planets occupy those houses, there is trouble through the progeny, and usually the loss of one or more during infancy is to be feared.

[Pg 82]

As to the number of children, no empirical rules exist for the judgment of this matter, which necessarily is a difficult one owing to the fact that we have no means of comparing the horoscopes of man and wife, but the nature of the sign on the cusp of the 5th House is usually to be depended upon for an approximation. Thus Aries, Leo, and Capricornus give small families. Taurus, Cancer, Virgo, Scorpio, and Pisces give large families, and the other signs yield a moderate family. When the Moon is strong, angular, and not afflicted, the number is increased. Twins are born from double-bodied signs occupying the cusp of the 5th House, or planets in the 5th in a double-bodied sign.

zaid n. adwan

The condition of each child is known in a general manner from the alternate Houses, commencing with the 5th. Thus the first child is (in a male horoscope) ruled by the 5th House, and planets therein; the second child by the 7th House; the third by the 9th House, and so on. In a female horoscope the first child is ruled by the 4th House; the second by the 6th House, and so on.

Thus if it be found that there is probability of loss of some of the progeny, the children most liable to affliction may be known by this method; for the Houses which contain the malefic planets, or the afflicted planets, correspond to the afflicted progeny.

Illustrious children are born to the Subject when the ruler of the 5th House is in elevation and well aspected, and in a congenial sign. But if the ruler of the 5th House be badly placed and aspected and in a sign of debility, *i.e.*, opposite to one over which it rules, then the progeny are ill-equipped for the battle of life, either mentally or morally. The particular qualities and[Pg 83] fortunes of the progeny can only be known from their individual horoscopes.

When malefic planets hold the 12th House in a female horoscope, there will be danger in confinement; and the same happens if either of the luminaries, but particularly the Moon, be afflicted in the 5th House.

[Pg 84]

CHAPTER X

VOYAGES AND JOURNEYS

The indications of short journeys, inland and around the coast, are to be judged from the 3rd House and the planets therein. If a movable sign be on the cusp of the 3rd House,

zaid n. adwan

or planets in a movable sign occupy the 3rd House, then there will be much travelling and many short journeys to and fro. The aspects to these planets in the 3rd will indicate whether such journeys will be mainly successful or not. When there are no aspects to the planet or planets in the 3rd House the fortune of short journeys is to be judged from the nature of the planet in the 3rd, as if Jupiter, they will be fortunate and lucrative; but if Saturn, unfortunate and subject to many hindrances and delays. When malefic planets are afflicted in the 3rd House, or malefic planets in the 3rd throw evil aspects to the Sun or Moon, then there will be dangers and accidents.

Watery signs on the cusp of the 3rd House, or planets in watery signs in the 3rd, indicate cruising and yachting, short journeys by water around the coast. If the Moon be in good aspect to these planets, then there will be safety in passage; but if afflicted by[Pg 85] the planets in the 3rd there will be danger of collision, capsizing, &c., according to the nature of the planet in the 3rd House.

Long voyages are to be judged in exactly similar manner from the 9th House, the planets therein and their aspects.

The 4th House indicates the place of birth, and if this House hold a benefic planet, or either the Sun or Moon, well aspected, then there is fortune in the place of birth, and journeys should only be undertaken when they are without doubt fortunate in their issues and admit of a return to the native place. When, however, the 4th House is occupied by evil planets or planets heavily afflicted, it will be advisable to remove from the place of birth and seek fortune in more propitious localities.

In this matter the choice is made by reference to that planet which holds the greatest power for good in the horoscope of birth, and the quarter of the Heavens which it occupies will indicate the direction, as from the place of birth, to which the Subject should repair.

Zain. adwan

Thus, if between the East horizon and the meridian, South-east; between the meridian and the West horizon, South-west; and so of the rest. The points of the compass follow the cardinal points of the Heavens, the Midheaven being South; the Nadir, North; the Ascendant, East; and the Descendant, West. If a malefic planet is rising or setting at birth it is advisable to fix the place of residence so much to the Eastward of the birthplace as will suffice to bring the malefic planets out of the angles of the horoscope. The same if malefic planets occupy the 10th or 4th Houses. On the contrary, if benefic planets are in the 3rd and 9th[Pg 86] Houses the Subject should move Westward so as to bring the benefic influences into the 10th and 4th Houses.

When benefic planets or planets well aspected occupy the angles of the figure at birth the Subject should not travel far, nor reside long away from the place of birth.

Indications of many voyages are as follows: Many planets in watery signs, Cancer, Scorpio, and Pisces, and also in the sign Virgo. When the majority of the planets are in cardinal and flexed signs, Aries, Gemini, Cancer, Virgo, Libra, Sagittarius, Capricornus, and Pisces, there will be many changes and journeys. Also if the Sun, Moon, Mars, and Mercury are in either the 3rd, 9th, 12th, or 6th Houses, there will be many journeys and long explorations in foreign countries.

When planets are afflicted in watery signs there will be danger in voyages, and if the Moon or Sun be afflicted in Virgo there will be submersion due to wreck.

Also, when there are planets, especially malefics, in Scorpio, Leo, Taurus, and Aquarius, afflicted by the aspects of other planets, or themselves afflicting the Sun or Moon, then there is danger of drowning.

When the signs of voyaging are propitious, and especially when the indications in the 4th House are not so, then removal from the place of birth to some other permanent centre of activity will be advisable. But when good planets or planets well aspected are

either rising or in the 4th House, the Subject should remain in his native place, and in the end his patience will be justified.

[Pg 87]

CHAPTER XI

OF FRIENDS AND ENEMIES

The general harmony of the horoscope consists in the positions and aspects of the planets and their relations with the luminaries. When this is conspicuous there will be many friends and supporters, and the associations of the Subject will be pleasant and profitable. But when the horoscope is fraught with evil aspects and angular positions of the malefics there will be much strife and many enmities.

In a particular sense the friends and associations of the Subject are to be known from the 11th House and the planets therein. For if there be a benefic planet in the 11th, especially if in good aspect to either of the luminaries, there will be many friends and adherents.

Similarly, the enemies of the Subject are known from the 7th House, and secret enemies from the 12th. Malefic planets therein, especially in evil aspect to the Sun or Moon, shows many opponents.

Neptune in any malefic aspect to the Sun or Moon shows danger of deceit and treachery being practised[Pg 88] upon the Subject, and if violent testimonies concur from the ill aspects of Mars or Uranus he will be in danger of an ambush. Saturn in the 7th or 12th shows long feuds and implacable enmities. Uranus therein shows litigation and heckling

zaid.adwan

of creditors. Mars therein is an index of violence and passionate hatred. Mercury therein shows much scandal and many petty annoyances.

Now observe the places of the malefic planets and the Houses wherein they are situated. Take the date when the Sun is in the same longitude as any of these malefic planets, which will be the same in any year, and this will be the birthday of persons who are to be avoided as likely to bring mischief into the life. Supposing, for instance, that Saturn is found at birth in the 10th House, in the 13th degree of the sign Aquarius. Reference to the Ephemeris (Sect. II., chap. i.) will show that the Sun is in Aquarius 13 on the 1st and 2nd February. Hence it would be unfortunate for the Subject to serve any man who was born between the 28th January and the 3rd February in any year. Also, if Uranus were in Leo 23 in the 7th House he should not go into partnership or marriage with anybody born on or near the 15th August in any year.

Take now the places of the benefic planets, and also the place of the Moon, and find the corresponding Solar dates, for these will be the birth dates of such persons as should be cultivated and drawn into close association for mutual benefit.

Observe also the trines and sextiles of the benefic planets and of the Moon, and the squares and opposi[Pg 89]tions of the malefics, for these will operate in a minor degree in a similar manner as already indicated.

A comparison of the horoscopes of persons, whether kings or plebeians, with those of others who have wrought great good or evil in their lives, will immediately establish this observation. Indeed there is nothing more dependable in the whole range of scientific observation than this sympathy and antipathy of horoscopes and their corresponding results. It is an argument for the claim of its advocates that Astrology should be regarded in the light of a science, for if the planets act not at all upon the dispositions and tendencies of men their squares and oppositions in two separate horoscopes would have no signification. Let those who are unhappily mated compare their horoscopes and they will find the signs of discord to which reference has been

made above. On the other hand, let any man who has been lifted to wealth, fame, or position by the patronage of another compare his horoscope with that of his benefactor, and it will be found that the benefic planets in the latter hold the places of the Sun, Moon, Midheaven, or Ascendant in his own. This frequently accounts for the fact that men with comparatively unfortunate horoscopes are sometimes found in positions of influence and in the enjoyment of considerable fortune. The complex fabric of life has its warp and woof wherein many coloured threads are woven together for the completing of the grand design, and the great loom of life has its wheels within wheels which only the Great Artificer can understand and regulate. We here below, subjects all of interplanetary action, must content ourselves with the design as[Pg 90] revealed to us in the history of mankind, or we must seek to understand the purpose of life, its motif, the complex laws which operate to bring about the unfoldment of the great plan, and thence to prognosticate that which hereafter shall be revealed to the commonplace observer.

[Pg 91]

CHAPTER XII

THE END OF LIFE

The end of life is judged from the planets occupying the 8th and 4th Houses, for the 8th denotes Death, and the 4th denotes the final resting-place of man. When benefic planets, or the Luminaries well aspected, occupy these Houses, you may judge that the end will be peaceful, normal, and that death will take place in the midst of congenial and even exceptionally agreeable surroundings.

When, however, the malefic planets hold these Houses, or afflict the luminaries therein, you may judge greater stress and privation.

Uranus in the 8th House denotes a sudden death, and the same result is observed when the Luminaries therein are afflicted by Uranus. Neptune in the 8th denotes danger of trance, coma, and simulated death, and when this position is observed it is necessary that all the signs of mortification should be present before interment is effected. Saturn produces death by privation and obstructions, by chills and colds. Mars induces death by fevers and inflammatory action, and frequently by hæmorrhage.

[Pg 92]

Planets in Fixed signs in the 8th House show death from heart or throat affections, affections of the excretory system and the blood. In Cardinal signs, the head, stomach, kidneys, or skin are the seats of the fatal disease. In Flexed signs, the lungs, bowels, and nervous system become fatally affected.

Violent or unnatural deaths are shown when either of the luminaries is simultaneously afflicted by the evil aspects of more than one of the malefic planets, or when both luminaries are separately afflicted by the malefic aspects of malefic planets, Neptune, Uranus, Saturn, or Mars.

When these testimonies occur, it will be found that Neptune produces death by assassination, Uranus by sudden catastrophes, explosions, hurts by electricity and machinery, Saturn by blows and falls, and Mars by cuts, burns, scalds, and effusion of blood. Particular judgment is drawn from the nature of the signs in which the significant planets are placed. Thus Saturn in Watery signs would produce drowning; in Taurus, strangling or decapitation; in Aries by the blow of a truncheon, &c. Similarly, Uranus in Gemini would produce accidents on short journeys, railway collisions, bicycle or motor accidents, and the like effects. It is impossible to cite all the effects due to the several planets in the different signs, but if the simple natures of the planets, signs and Houses are thoroughly understood, a combination of their significations will readily

Zaid n. adwan

lead to an appreciation of exact effects. If I say that a certain fluid is H_2SO_4, any one having a knowledge of elementary chemistry will know that it is sulphuric acid, and similarly, if I say that a certain horoscope contains Saturn in Cancer in[Pg 93] the 3rd, which is astrologically expressed ♄ ♋ 3, any one who has read the first pages of this book with attention will be able to say: Let the Subject beware of short journeys by water! It is all chemistry of a kind.

When the 4th House contains benefic planets, or planets that throw good aspects to the luminaries, there will be peace and comfort in old age, or in the end of life whensoever it may be determined. Neptune therein shows retirement and sequestration, and when afflicting the luminaries or itself afflicted, it denotes death in an asylum, hospital, or other place of detention. Uranus in the 4th, in similar conditions, denotes a sudden and remarkable death. Saturn similarly placed and aspected shows death in exile, privation or great trouble. Mars in the 4th House afflicting the luminaries or itself afflicted by other adverse planets, denotes a violent death by gunshot or wound and in the midst of strife, or on the field of battle.

Before any catastrophic death be predicted, it should be carefully decided whether or not the death is compassed with uncommon and violent indications, not that one need have fear of the mere going out or coming into the world, but there is some choice of gates, and rather than affright the weak-minded with a sinister judgment, it is better to leave them to find their own way.

[Pg 94]

SECTION IV

THE STARS IN THEIR COURSES

CHAPTER I

THE TIME-MEASURE

The planets, in their motions after birth, come into certain relations with the planets in the horoscope of birth, and also form aspects among themselves owing to the diversities of their motions in the Zodiac. In Astrological science there are two separate means of calculating the time of events, but both methods consist of bringing the body of one planet to the body or aspect of another, which process is called "Directing," and the arc described by the moving body is called an "Arc of Direction."

The first of these methods is the discovery of Claudius Ptolemy, the famous mathematician and geographer, the author of the Syntaxis, as set forth in his work the Tetrabiblos, or Four Books on the influence of the Stars. This method had the support and confirmation of the great Kepler. It has respect to the rising, setting, and[Pg 95] meridian passage of the planets after birth, whereby they are brought to the places or aspects of the planets in the Radix (the Root), which is the horoscope of birth.

The limits and nature of this work do not permit of a thorough exposition of this method, which entails some little knowledge of spherical trigonometry, but the reader who desires to perfect himself therein is referred to the author's work, entitled "Prognostic Astronomy." A facile application of the method is here given, by which any one may,

Zaid H. adwan

by the aid of the Tables of Houses, make certain of the more important calculations by rule of thumb, and predict thence the times of remarkable events.

The principle involved is this: The number of degrees which pass over the meridian between the moment of birth and the rising or culminating of a planet, will equal the number of years which must elapse from birth until the influence of that planet becomes dominant.

Thus, if Jupiter at birth is coming to the meridian, that is to say, if it be in the 10th, 11th, or 12th House, count the number of degrees between the meridian and Jupiter, and in so many years from the time of birth there will be an access of good fortune. Similarly, if Saturn or other of the malefic planets be coming to the meridian, the number of degrees between it and the Midheaven will indicate the age at which troubles will abound.

Also, when the planets have passed the meridian, the measure is made in the same way, by bringing the Midheaven to the place of the planet, counting the degrees between the planet and Midheaven for the number of years at which it will operate.

[Pg 96]

But the same and other planets may be directed to the horizon, by taking the Table of Houses for the latitude of the birthplace (Sect. I., chap. iii.) and finding therein under the column marked "Ascen." (Ascendant) the longitude held by any of the planets. Observe then what degree is on the Midheaven in the column marked 10 (10th House), and count the number of degrees between this Midheaven and the Midheaven at birth. The result will give the age at which the effects of such planets will be experienced.

Thus, for a person born in or near Liverpool or in the same latitude, suppose the Midheaven at birth to be in Scorpio 0, and Saturn to be in the 2nd House in Aquarius 8 degrees. I wish to bring Saturn to the horizon. In the Table of Houses I find that Aquarius 8 is on the Ascendant when Sagittarius 9 is on the Midheaven, and I therefore

count from Scorpio 0 to Sagittarius 9. This gives the age of 39 years, and as Saturn is in the 2nd House at birth, I say that at 39 years of age the Subject would experience financial disaster, and because Saturn comes then to the Ascendant, I also say there would be serious illness and depression of spirits.

When planets are setting at birth they are brought to the opposition of the Ascendant in a similar manner, only the opposite point of the zodiac must be found in the Tables under the Ascendant. Thus, if Mars were in the 7th House at birth in the 11th degree of Cancer, I find the opposite point (Capricornus 11) under the column of the Ascendant, and I note that Scorpio 19 is then on the Midheaven, so that from Scorpio 0 to Scorpio 19 gives 19 years, at which age the Subject would have a serious[Pg 97] illness due to inflammatory action in the stomach and probably produced by overwork and worry, as indicated by the sign Cancer and the planet Mars, or if there be indications of an accident, then an accident by scalding with hot water or acids would be predicted.

Planets are brought to the opposition of the Midheaven by counting the degrees which intervene between the longitude on the lower meridian at birth and that held by the planet.

In all such directions the conjunctions of benefic planets are advantageous when directed to the Midheaven or Ascendant, and the conjunctions of the malefics are indicated of periods of bad fortune. The oppositions are uniformly evil, whether the planet involved in the direction be a benefic or malefic. (Sect. I., chap. iv.)

These are the directions of the planets to the two Significators, the Midheaven and Ascendant. The Midheaven appertains to honours and credit, while the Ascendant has relation to the personal and bodily welfare and the general fortunes.

To direct the Midheaven or Ascendant to the other aspects of the planets, such as the sextile, trine, semisquare or square, it is only necessary to note the degrees in which

Zaid n. adwan

these aspects fall and bring them to the Midheaven or Ascendant as if the body of the planet were itself there, and in the manner already indicated.

The Sun is directed after birth by its motion in the zodiac, which can be found in the Ephemeris for the year of birth, and the aspects it forms to the planets in the horoscope and in the daily progress should be tabulated. In most Ephemerides they are already cal[Pg 98]culated, so that the labour is considerably lightened. Each day after birth will represent one year of life, the mean motion of the Sun being about 1 degree per day. All that is necessary, therefore, is to count the number of days from birth to the date when the Sun forms an aspect, and that will give the age at which the planet aspected will produce its effects.

As the Sun goes through the zodiac the other bodies make progress along with it, in which course they form aspects to the Midheaven, Ascendant, the Sun and Moon in the horoscope of birth. These are called “Secondary” directions, and in connection with the Sun’s aspects after birth, constituted the system in use among the Arabian astrologers.

Minor periods of good and bad fortune, subsidiary to the above periodic influences, are taken from the Moon’s progress after birth, in which one day equals one year of life, and two hours equal one month. These directions of the Moon afford a monthly prognosis of the course of events, and are useful in the conduct of minor affairs in life. When they are contrary to the general trend and import of the periodic directions made to the Midheaven, Ascendant and Sun, they act indifferently, and frequently produce only passing benefits or annoyances; but when they are in agreement with the Primary Directions cited above, then they accentuate and define the nature and time of events. As if the Primaries be good and the Lunar directions evil, then there will be a predominance of good fortune with some current disturbances; but both being good there will be abundant success and satisfaction; while if the Primaries be evil and the Lunar directions good, the latter will serve only[Pg 99] to moderate the effects for the time being of the Primary evil indications.

An intelligent apercu of the principles of directing will greatly enhance the value of any prognostications made from the horoscope of birth, as it will enable the student to select those periods in the life when the effects due to any planet are most likely to eventuate. Thus, if Saturn be in the 2nd House at birth, it may be said that there would follow some periods of great financial stress, and the rising of Saturn by direction after birth would show the time when one, at all events, of such periods would be experienced.

And here is the great fact upon which astrologers the world over are prepared to stand or fall. If the planets have no effect in the lives of men, their directions to the angles of the horoscope can have no effect; but never was it found that a man had evil fortunes at the period when the planet Jupiter was directed to the Midheaven or Ascendant, or anything but bad fortune when Saturn was similarly directed. The fact is there, and we cannot get away from it. The only question is as to how far we can intelligently carry our investigations beyond that point, and intelligibly convey our discoveries to the world by their application to the affairs of daily life. The reader may judge for himself from a perusal of these pages.

The directions being calculated and tabulated in order of their occurrence, the time and general nature of the influences operating in successive periods of the life will stand revealed. The particular nature of the events indicated by the several directions may be known from (*a*) the House in which the directed planet is situated;[Pg 100] (*b*) the Sign it occupies; and (*c*) the aspect it forms, considered in relation to the nature of the planet. For example: If Uranus at birth were in the 9th House and the sign Gemini, its direction to the Midheaven would be the index of litigation in connection with writings, publications, or means of transit; because the 9th House, among other things, has relation to litigation and legal affairs, and Gemini (the 3rd House sign) to communications, writings, &c., while Uranus denotes sudden and unexpected events, ruptures, alienations, and complexities.

So if Saturn were in the 6th House in the sign Aquarius, its direction to the opposition of the Ascendant would indicate chills to the blood, anemia, &c., constituting a serious illness with probability of low fever; because the 6th House rules sickness, and Aquarius rules the blood, while Saturn is the cause of chills, paucity, and impediments.

Thus the time and nature of events may be known with great certainty.

[Pg 101]

CHAPTER II

THE EFFECTS OF TRANSITS

Among the number of important indicators to which Astrologers refer in making a forecast of concurrent events, there are the transits of the planets over the places of the Significators at birth, the positions of Eclipses, and those of the lunations.

The first of these chronocrators depends upon the revolutions of the planets in their orbits. Each planet has a period in which it completes its revolution in the heavens, in the course of which it passes the places of the Sun, Moon, Midheaven, and Ascendant of the horoscope. This passage over the radical Significators is technically termed its "transit," and it will be found that such transits afford a very precise and reliable source of prognostication, for the time of a planet's transit is known in advance of its occurrence (see Sect. II., chap. iv.), and the effects of such transit are in exact terms of the nature of the planet concerned. It is only necessary to add that the Midheaven and the Sun have relation to the position and honour of the Subject, while the Moon and Ascendant have relation to the personal health and general fortunes. The Sun[Pg 102] and Midheaven also signify the father, and the Moon has general signification of the mother.

Venus signifies domestic and love affairs, the affections and sentiments; while Mercury signifies the mental disposition. So Uranus in transit over the place of Venus will give a love affair, a romantic attachment. Mars over the place of Venus will engender passionate love. Saturn over Venus will give disappointment or bereavement; and Neptune thereover will bring entanglements and complications, with danger of being led astray. Saturn over Mercury will produce melancholy and many errors of judgment. Mars over the same planet will excite the mind and dispose to impulse and unreasoning anger, quarrels and disputation. Uranus over Mercury will render the mind wayward and headstrong, disposed to erratic courses and egotistic methods. Neptune passing the place of Mercury produces deceits, treacheries, and apprehension of impending evil, a sense of espionage and ambush. It involves the mind in tortuous and complicated schemes, and disposes to secrecy and wariness.

The transits of the major planets are of chief significance, and their effects are rendered more weighty and lasting when at the time of transit they are retrograde in the zodiac; while their stationary positions on the places of the Significators have almost the same power as Primary Directions.

Of Eclipses.

An Eclipse of the Sun or Moon falling on the place of any Significator in the horoscope of birth is of a sinister import, and cannot be too seriously considered. Falling[Pg 103] on the Ascendant or the Moon they affect the health and general fortunes very seriously, and only a series of subsequent good directions can avail to restore the Subject to his normal condition. On the Midheaven or the Sun, the honour and fortunes may both be affected, and in the same serious degree. The Eclipses falling on the places of the other planets will produce effects in accord with the nature of those planets and the Houses they occupy. To have any appreciable effect, the Eclipses must be within two degrees of any of the radical positions, or of their opposition aspects.

Of Lunations.

The Lunations recur in the same part of the Ecliptic every nineteen years. Considered in relation to the current indications they afford the means of a monthly forecast of events. Thus, if the lunation for the month falls on the place of Jupiter in the horoscope of birth, it will produce good effects in that department of life which is governed by the House in which Jupiter is situated; as if in the 11th, through friends; in the 4th, through property or rental; in the 6th, through servants and health; in the 8th, through a financial colleague, &c.

The effects of Lunations are subsidiary to the current Lunar directions, and these in turn are subsidiary to the transits, and the transits to the Primary Directions. By this it is not meant that they are inoperative, nor that they fail to indicate the events of the month, but their power and degree of influence is subject to the greater influence of superior causes. And as a general observation it may be affirmed that the less frequently any celestial position occurs in a horoscope, the greater is its[Pg 104] influence. This fact gives to primary directions their great influence in the life, for they can only occur once in a lifetime; and for the same reason Eclipses have a major significance, for the same Eclipse only recurs after an interval of 649 years. The transits of Neptune, of Uranus, of Saturn and Jupiter and Mars follow in their order of frequency. Neptune has a revolution of about 165 years, Uranus 84 years, Saturn 30 years, Jupiter 12 years, and Mars 1¼ years.

Major effects must not therefore be referred to inferior causes, and minor effects must not be referred to superior causes. In universal or even national cataclysms, individual fortunes are submerged.

[Pg 105]

CHAPTER III

HOW TO SUMMARISE A HOROSCOPE

Before leaving the exposition of this subject, it may be of advantage to the reader if I give some idea of the method to be pursued in the complete handling of a horoscope.

First, then, erect the figure of birth, taking care to use the Ephemeris of the year of birth, and also the correct Table of Houses for the latitude of the place of birth.

Next proceed to attempt a description of the chief personal traits of the Subject, following in succession with a well-considered judgment on the constitution, hereditary tendencies, the health and pathological predispositions, the mental traits and disposition, considering these latter in relation to the state of health indicated. Then pass to a consideration of the environing conditions of life; the financial condition and outlook; the position in life; the occupation; prospects and conditions of marriage; of progeny. Judge next concerning voyages and journeys. Finish with a statement regarding the predominance of friends or enemies, and select dates by Solar positions, as already instructed. In cases where it is not objected[Pg 106] to, an approximation may be made to the time and nature of death.

Throughout the whole of this judgment, the periods when these predicted effects will come into force should be made by reference to the rising, setting, and meridian passage of the planets, the solar aspects, and transits.

Care should be taken to weigh justly and impartially the evidence set before you in the figure of the heavens for birth. Major importance should be given to those planets which are in angles, and those which are in elevation, for the nearer a planet may be to the Midheaven, the greater is its influence for good or ill, according to its nature and aspect.

Read what you see, not what you imagine should be the destiny of an individual. If you are in complete ignorance of his person, position, and environment, so much the better.

If you follow carefully the various rules which are contained in this book, you may at first make some errors of judgment, but as you become familiar with the task, even these errors will become few and far between, and in the end the language of the horoscope will become so intelligible and clear that it will interpret itself, and the whole trend and potentiality for good or ill of any birth-figure will force itself upon you in just the same way as when a man walks into your presence with his character clearly stamped upon his face, so that you have only to look and know.

Having become proficient in the judgment of birth-figures, you will do well to proceed to a closer study of the mathematics of astrology, making yourself proficient in the various methods of directing, so that you may at[Pg 107] any time refine upon your general prognostics, and make predictions which are clear, sharp, and to the point.

Undoubtedly there is a modicum of intuitive perception at work in the judgment of any horoscope, which will enable you to seize upon the small details and exact pointing of any matter, and this perhaps constitutes the whole difference between the rule of thumb worker and the inspirational reasoning of the intuitive worker. The one exhausts the books and the other embellishes them. It is so with science in every department. The books will take you up to a certain point of proficiency, and a strict regard for the formulæ will keep you within the bounds of safety. But if you are ever to make a discovery or become a recognised exponent of any science, you must be naturally gifted with what is called the "scientific imagination," another name for intuition. But at no point does true intuition part company with exact reasoning. There is no lesion. The one is an extension of the other. It is the higher reason, which argues from the known to the unknown. And the Astrologer is in this respect as the poet, "born, not made." But a moment's reflection will suffice to convince you that the more facile you may become with the book-learning and technique of Astrology, the more you will leave the intuition free to act. When a lad is struggling with his multiplication tables, his appreciation of the binomial theorem or the differential calculus cannot be said to amount to much.

zain.adwan

And, in the same way, a person who is stuffing down the Alphabet of Astrology cannot be expected to intuit anything concerning the potential of the Sun's direction to the quadrature of Saturn.

[Pg 108]

CHAPTER IV

HOW TO BECOME A SUCCESSFUL ASTROLOGER

I take it that nobody nowadays can afford to fritter away time in the study of subjects which are not likely to become a source of benefit to himself and others. If there be such people among my readers, which I consider unlikely, I may dismiss them offhand with the remark that they will never become successful astrologers, for the first word of practical astrology is Utility. If the science had not its practical application to the affairs of everyday life, if its principles contained no word of assurance and hope for the myriad toilers of this world, no word of admonition for the self-indulgent parasites of modern social life, if, in short, it did not make for the betterment of human life and thought, it would never have attracted the attention of Aristotle, Cicero, Galen, Claudius Ptolemy, Thales, and others of the old world, and such men as Bacon, Cardan, Archbishop Usher, Naibod, Mercator, Ashmole, Kenelm Digby, Sir Christopher Heydon, Dryden, Dr. John Butler, Sir George Wharton, Vincent Wing, George Witchel, Tycho Brahe, Kepler, and Flamstead of more recent biography. Indeed, in whatever age or country[Pg 109] we may elect to make our inquiries concerning Astrology, there are to be found a host of intelligent and even illustrious advocates in every department of life and learning. Suffice it to say that the modern student of this most ancient of all sciences is at all times in very good company.

Let it first be understood that there is an object to be attained in the study of Astrology, and that the pursuit of it in the gratification of an idle curiosity alone will inevitably entail the waste of time which invariably attaches to idleness of all descriptions, and we may then profitably consider whether or not the subject is worth the labour which it will demand from the man who has something to do in the world and little enough time in which to do it. These are stressful times, and we have to be economical in our efforts. We have strength enough to carry us through, but neither strength enough to thresh the wind nor time enough to fish in puddles.

What, then, does Astrology offer to the patient worker, the man who would become a successful Astrologer?

First and foremost it will enable him to gain an insight into individual motive and character which no other science can possibly afford. It will enable him to know himself, his own strength and weakness, and so fit him to deal harmoniously and justly with others. It will enhance his opportunities to the extent that he is able to foresee and make use of all benefic influences operating through his own environment. It will give him timely warning of his approach to the quicksands and pitfalls which occur in his passage through life. He[Pg 110] will discern his special physical weaknesses, and the times of his predisposition to sickness, the nature thereof, and the precautions which are necessary. He will know whom to cultivate and whom to avoid, and in selecting a partner in business or a wife for his home, he will be guided by a foreknowledge of evils to be avoided and of good things to be gained. He will choose his path in life with the confidence that it is for him the line of least resistance and therefore that of greatest progress. He will not become obsessed by ambitions beyond his power to achieve. He will learn the power of adaptation to environment, and thereby effect his work in the world with the least possible friction and waste of force. He will know when to make provision against sickness, accident, and death. He will not invest capital where interest is not to be gained. He will see the end from the beginning. It may not make him a

brilliant success in the world, but it will assuredly save him from being a failure. He will find causes for inexplicable things, and his mind will rest content in the knowledge hat while he is working out the highest potentialities of his own horoscope, the major problems and intricacies of life are not of his making or needful of his solving. And finally, when his time comes to "shuffle off this mortal coil," he will be prepared, and will know that it is the will of Heaven, expressed and determined from the moment of his birth. Rightly employed, Astrology cannot fail to improve the man who makes of it a serious study, fitting him to be of greater use to others and of higher service to the race at large.

But to become a successful Astrologer he must study[Pg 111] patiently for several years, testing each statement that is made in the books by reference to his own and several other horoscopes. He must be able to erect a figure of the Heavens with mathematical accuracy for any given time and place, work out directions by the use of the sphere or trigonometrical tables, and have a competent knowledge of the motions and periods of the various planetary bodies. When thus satisfied in his own mind that Astrology is a dependable science, and that he is capable of demonstrating it under test conditions, he must be generous in the use of it. Here and there he will find one who is opposed to the belief that the stars have any influence in human affairs. Let him not waste logic with such a man, but go straight to the task of convincing him by an appeal to facts.

For preference, select a period when the directional influences are such as seem likely to hit the sceptic with considerable force, define the event, make a careful calculation of the time of its fulfilment, and put them on paper, which, being yet unread by the man of Common-sense, should be placed under cover, sealed, and endorsed to be opened only after a certain date.

Now a man who has been hammered rather severely and in quite an unexpected manner, is usually open to conviction of truth when he finds that the nature and date of his disaster have been accurately foretold. Being a man of "common-sense" and not of

intuition, he will probably think that the Astrologer might even have saved him from the consequences of his own lack of foresight. So indeed might the Astrologer have done had he taken the management of affairs from the beginning; but to step in half-way to arrest causes which are already in operation[Pg 112] and charged with inevitable effects, is requiring too much of any man short of a Prime Minister!

There are certain things which even the most astute deductive reasoner cannot foresee, and these are the points that should be utilised by the Astrologer who seeks to convince others of the truth of his science. A man cannot reason from his doorstep to a street accident. If he could he would avoid it. All men are not subject to accidents, however. But almost all are subject to bereavements, losses, sicknesses, and changes of fortune. Those are the points which the Astrologer intent on proselytising, usually makes use of. But events need not be in futurity to carry conviction. If it can be shown that by mathematical calculations the events of the past can be recited with precision and exactness, it is evident to the meanest intellect that nothing hinders from an extension of such calculations into the future. And once convinced of the reliability of such claims to foreknowledge, the practical man of the world is not slow to avail himself of its uses.

But Astrology is not exhausted in the study of individual horoscopes, for there are other departments of this extensive science. The influence of the planets upon the weather, as embodied in Astro-meteorology; the rise and fall of Empires, political changes, the outbreak of wars, of revolutions, of epidemics, as defined by State Astrology so much in repute among the Oriental rulers; the occurrence of tidal waves, earthquakes, and other seismic phenomena, all form a part of the complete equipment of the practical Astrologer.

It would be superfluous to recite here the numerous and strikingly accurate forecasts which have been made[Pg 113] by modern exponents of the science, but it is only right to say that they reflect considerable credit upon their authors, for the above-mentioned departments of astrological learning are by no means in the same efficient state as

Genethliacal Astrology, to an outline of which this work is devoted. Anciently it was otherwise, and even in the East at this day they hold some secrets of traditional knowledge, concerning which they are unduly mysterious and of which we have only the evidence afforded by more exact prediction upon certain points.

Prejudice and Ignorance are the twin giants which bar the path of the world's progress to-day, even as they have ever done. Step by step they have been beaten back, baffled by the light of Reason, harassed by the arrows of Truth. The world is redeeming its ancient heritage. All that is now required to establish the paramount truth of Astrology as a science is an impartial and thorough investigation, preferably at the hands of scientific men, of its methods and principles. Not that the truth is to be ratified at the hands of modern scientists, seeing that their own teaching constitutes a mere shifting orthodoxy, liable at any moment to undergo a fundamental change in theory by the discovery of a single new fact—but that to such men rightly belongs the duty of disproving the claims of Astrology to be considered as a science, for it is a fact to be regretted that certain members of their body have written against the subject in a spirit of prejudice and without adducing any data in support of their contention, which ill becomes any man of scientific pretensions and is above all things detrimental to the cause of Truth.

[Pg 114]

CHAPTER V

A POPULAR ILLUSTRATION

zaid n. adwan

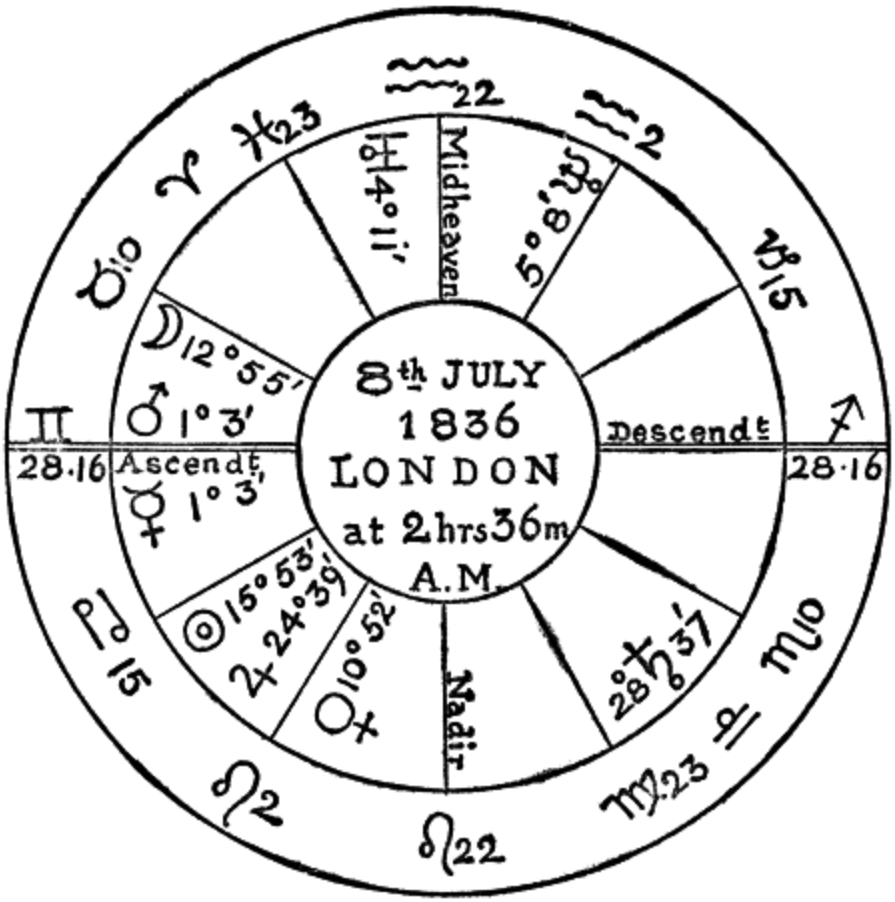
In order to summarise and illustrate the principles which have been enunciated in the course of this work, I shall avail myself of the horoscope of Mr. Joseph Chamberlain, who was born on the 8th of July, 1836, at Highbury, the time of birth being stated to have been at about 2.30 in the morning. Calculations have since enabled us to fix the exact time of birth as at 2 h. 36 m. a.m. I subjoin the horoscopical figure for that time, the calculation of which is as follows:—

	H.	M.	S.
Midheaven in R.A. at Noon 7th July, 1836…	7	1	58
Add time elapsed since … … …	14	36	0
Equation for 14h. 33m. at 10 secs.		2	25
Midheaven in Right Ascension at Birth …	21	40	23

The Constitution.

Born under the sign Gemini, with Mercury rising in the sign Cancer, the Sun near the conjunction with Jupiter and in close sextile to the Moon, there is little [Pg 115] [Pg 116]doubt that the late Colonial Secretary is by nature gifted with an excellent constitution. The sextile of the luminaries is a powerful co-ordinator, and whenever sickness supervenes there will be a speedy recovery. The semisquare aspect of Mars, while disposing to gouty affections of the hands and feet, will contribute vital energy and power to throw off diseases, while at the same time predisposing to accidents and wounds to the right shoulder or clavicle.

Zaid n. adwan



The rising sign gives nervous energy and enormous capacity for work, which is due to high nervous tension supported by a sound vitality. The only hereditary predisposition is that indicated by Mars, which induces to fevers, and gouty affections due to acidity.

The Health.

The Moon is strong in the sign Taurus, but not particularly well placed in the 12th House. It has, moreover, the square aspects of Neptune and Venus from fixed signs. These indications point to functional disorders of the heart, throat and excretory system. On the other hand, there are the good aspects of the Sun, Jupiter and Uranus to counteract these adverse tendencies, and it is certain that strong recuperative powers together with a normally good co-ordination of functions would induce a speedy recovery from any illness to which he may be liable. Considerable immunity from sickness of all sorts may therefore be predicated.

Character and Disposition.

The majority of the planets being in Cardinal signs, with three planets (including the Moon) in Fixed signs,[Pg 117] indicates a character that is energetic, ambitious, active, sharp, ingenious, lively, and persevering; capable of cutting out a line in life for himself and making headway against obstacles; disposed to ride roughshod over the weaknesses and prejudices of those who oppose him; gifted with a pioneer spirit, incisive manner, and disposed at times to effect his ends regardless of the feelings and opinions of others. At the same time there is sufficient patience, method, caution, and watchfulness to make this extreme definition of purpose very effective. Laborious, firm (at times obstinate), systematic, and self-reliant, he is capable of waiting for opportunities. But finally he carries his purpose with a *tour de force*.

That which he lacks is adaptability, suavity, and ability to enter into the feelings of others. He is too ambitious to be self-centred, but yet too intent to be sympathetic.

The rising of Mercury in trine aspect to Saturn and Uranus gives considerable mental capacity, a wide grasp of facts, a well-informed, apt and business-like mind; some originality, constructiveness, and power of marshalling facts and figures; patience, caution, and secrecy. There is not much imagination, and the sympathies are not wide. His methods and actions are governed by literal fact and mathematical certainty. He is an omnivorous devourer of the accessible. He takes the small fish by the handful and makes a meal of them; but he leaves the ponderous whales for those of greater imagination and more leisurely habit.

The quadrature of Mars to Uranus will induce momentary outbursts of temper and some irritability of nature, but the character I am delineating is not such[Pg 118] as can easily be played upon, for it is remarkably lacking in emotional susceptibility. Nevertheless, the inspirational faculty is by no means absent, and the presence of Neptune in the 9th House in trine to the rising Mercury, is an index of considerable inventive genius, extreme range of mental perception, and telescopic discernment of future events. Venus

in the 3rd House shows some artistic tastes and fancies, considerable appreciation of art and culture, a fondness for flowers, bright lights, &c. But dominant above all are the two angular influences of Uranus and Mercury, which render the mind mathematical and precise, commercial, apt, business-like, energetic, and eminently magnetic.

Finance.

The position of the Sun in conjunction with Jupiter in the sign Cancer, in sextile to the Moon, is the index of a high fortune and means exceeding a competence. It is here worthy of note that Cancer, which in this horoscope holds the Sun, Jupiter, and Mercury, is the ruling sign of South Africa, with which Colony Mr. Chamberlain's fortunes have been for a long time so intimately associated. It is also worthy of note that both Cecil Rhodes and Barney Barnato were born on the same day of the year, the 5th of July, with the Sun in the 14th degree of Cancer. In the former case the Sun was conjoined with Moon and Venus, in sextile to Uranus and trine to Neptune, while in the latter case the Sun was in trine to Jupiter. In regard to Mr. Chamberlain's horoscope, it will be observed that Jupiter, which holds such effective power for increase in the 2nd House, is also the ruler of the 7th, and it is to be remembered that all partnerships,[Pg 119] commercial or social, which he has contracted have so far proved highly satisfactory from a merely monetary point of view. Further, the Moon is affected with the good aspect of the Sun in the 2nd House, which is a further indication that on a purely financial basis Mr. Chamberlain is a man worth going into partnership with.

Position.

All the planets except Neptune and Saturn are rising, and this at once indicates a man ambitious of independence and honours, one who is confessedly a candidate for responsibility.

Uranus in the Midheaven and close to the meridian indicates that association with civic and governmental bodies in which Mr. Chamberlain has rendered himself so

conspicuous a figure, and whereas the trine aspect of Mercury in the Ascendant to Uranus in the Midheaven and the sextile of the Moon to Uranus also are sure indications of a wide popularity, the square aspect of Mars to Uranus from the 12th House, will not fail to engender many veiled enmities, machinations, and inimical plots, which have for their object the overthrow of Mr. Chamberlain's prestige, and which, failing, will find expression in vituperative abuse and bitter animosity. But those who understand the virtue of the orientality of planets in a horoscope will retain their confidence in Mr. Chamberlain's ability to hold his own against all opponents.

It will be observed that the direction of the Ascendant to the place of Uranus in the horoscope coincides with the age of Mr. Chamberlain at the outbreak of hostilities[Pg 120] in South Africa, while the direction of Midheaven opposition Saturn coincides with the progress of the Boer War. Did space permit it would be possible to adduce a long list of directional arcs coinciding with the time and nature of all the more important epochs in Mr. Chamberlain's career. The student is invited to make some test of this matter by the aid of the rules already given in these pages.

Marriage.

Mr. Chamberlain has been thrice married. It will be observed that not only is there a double-bodied sign on the cusp of the 7th House, but the Moon also applies to both the Sun and Jupiter in the sign Cancer. (See Sect. III., chap. 8.) The aspect of the Moon being benefic to both the Sun and Jupiter, the marital state would be both harmonious and fortunate. It is, of course, well known that Mr. Chamberlain has, from a merely worldly point of view, married most advantageously. This observation may be called "wise after the event," but I would observe that this geniture preceded my judgment of it, and the rules from which I judge are to be found in the Tetrabiblos of Ptolemy, written in the second century, and since tested and found reliable by successive astrologers during some seventeen centuries. Saturn's aspect to Jupiter, the ruler of the 7th House, and the

Moon's quadrature to Venus must be held accountable for the successive bereavements which have disturbed the conjugal life in this case.

Progeny.

The position of Saturn in the 5th House, and the[Pg 121] affliction of Venus by Neptune and the Moon, will serve to account, in connection with the marriage conditions, for the small family which has been born to Mr. Chamberlain, for observe that Venus is the ruler, jointly with Mercury, of the 5th House, while Saturn is in the 5th and ruler of the 8th House. The same positions and aspects threaten to curtail the succession.

The position of Mercury, joint ruler of the 5th, in the sign Cancer, and just about to rise in the horoscope, promises honours and distinctions to the first-born.

Travelling.

The Moon and Mars are cadent in the Horoscope, and Mercury, the "winged messenger" (symbol of the trading-ship), is rising. These are indications of many journeys and changes and constant unrest. But fixed signs being on the cusps of the 3rd and 9th Houses, and the Moon also in a fixed sign, will suffice to account for the fact that Mr. Chamberlain is not a great long-distance traveller. Cancer and Leo holding the benefics and the Sun also well aspected in Cancer, the Moon being in Taurus, shows at once that France, South Africa, Holland, Scotland, and Ireland are parts of the world in which the operations of Mr. Chamberlain would meet with success, if it be not superfluous to detail specific territories in face of the abundant evidence of general success which this horoscope affords.

Friends and Enemies.

It was the boast of Bismarck that he was the "best-hated man in Europe," and it would be strange indeed if Mr. Chamberlain had passed through life and attained so[Pg 122] prominent a position without incurring the enmity, or arousing the envy and malice

of a considerable number of individuals. Nevertheless, there are only two aspects in this horoscope which seem to point to any sort of trouble from such causes. The points are those of Neptune, which afflicts both the Moon and Venus, and of Mars which afflicts Uranus in the Midheaven and the Sun in the 2nd House.

By referring these two points to the Ecliptic we find they correspond to the Sun's position on or about the 24th of May, and the 26th of January, and I shall leave the reader to look up his Almanac and find the individuals (illustrious they must needs be to find chronicle in Whittaker) who were capable of filling the requirements of the case.

As to friends, Mr. Chamberlain should lack nothing. With the Moon in sextile to the Sun and Jupiter, the ruler of the 11th House, in the same benefic relations with the Moon, he would always be able to count upon a strong adherence, and the only adverse indication in this matter is that Mars, part ruler of the 11th House, holds the 12th House in square aspect to Uranus in the Midheaven. This would be interpreted to mean that some of his friends will be disposed to become his enemies, and to militate, although ineffectually, against his credit and position. Why ineffectually? Because Mercury, the ruler of the Ascendant and prime significator of Mr. Chamberlain, is angular and well aspected, while Mars is weak and afflicted by Uranus which is in elevation above it.

[Pg 123]

Conclusion.

Let it not be thought that the fame and position which Mr. Chamberlain has attained in the political world is due entirely to the benefic position of the principal planets in his horoscope of birth. Opportunity is not everything. The ability to use it counts for much, and only a man of exceptional industry, firmness, and decision, could have won for himself such peculiar distinction; and only a man of singular faculty could have sustained his position in the face of so much determined opposition. It will doubtless be a matter of extreme interest to the student of this horoscope, as to every one interested

zaid n. adwan

in the political situation of to-day, to observe the concurrent influences at work in the year 1904–5. Mr. Chamberlain attained his sixty-eighth birthday anniversary on the 8th of July, 1904, and by adding that number of degrees to the 22nd degree of Aquarius we obtain Taurus 0 as the point which has attained the meridian by "direction." This is called the Progressed Midheaven. Referring this point of the Zodiac to the places of the planets at birth, it is observed that the Midheaven is approaching the sextile aspect of Mercury, having recently passed the opposition of Saturn, and having attained that aspect in 1905, it passes in 1908 to the sextile of Uranus, the planet which holds the greatest elevation in the horoscope of birth. The Ascendant under the Midheaven of Taurus 0 is Leo 16° 28′, which is the Progressed Ascendant for the year 1904. It is in semisquare aspect to Mercury, and is the occasion of many anxieties, worries, and annoyances, and some journeys by water.[Pg 124] It also indicates some derangement of the health due to nervous strain, and affecting the stomach (ruled by Cancer). The Sun is directed in similar manner to the 24th degree of the sign Virgo, where it meets the sextile aspect of Jupiter in the 2nd House, in the sign of its exaltation, Cancer. This gives access of good fortune, increase of honor and prestige, and as Jupiter rules the 11th House, many adherents and supporters. But being also in semisquare to Venus, Mr. Chamberlain is in danger of losing a brother or other near male relative. The Moon by the same measure is within 4 degrees of the place of Jupiter, again marking the year 1908 as one of exceptional advantage, and in July of that year Jupiter passes over the Progressed Ascendant.

During the year 1904 Saturn has been close to the Midheaven of the radical horoscope, being in Aquarius 21, and stationary therein, during the month of June. In March, and again in October, it transits the opposition of the Progressed Ascendant in Aquarius 16,

while in February, June, and December Uranus is in transit over the opposition of the radical Ascendant in Sagittarius 28° 16′.

In 1905, Saturn will transit the Midheaven in the horoscope of birth, and in the summer of the same year Mars will be Stationary in opposition to the place of the Moon at birth. Both these periods will be fraught with cares and anxieties, and the latter influence will act detrimentally on the health, disposing to attacks of gout and inflammatory action in the system.

But while the approaching and concurrent Primary directions are of a highly benefic nature, there will be no hint of a breakdown either in health or reputation, and[Pg 125] it needs only the additional good influence of a transit or Secondary Lunar direction to carry Mr. Chamberlain at full swing to the summit of popular esteem and political power.

The curious who seek for coincidences will not be surprised and may be gratified to note that Merx, the root of the name of Mercury, signifies trade, and that the planet Mercury is rising in this horoscope of Mr. Chamberlain, who won great distinction for himself as President of the Board of Trade. Those who in more earnest vein seek for causes will do well to trace the transits of the major planets through this horoscope over the places of the Significators, the Sun, Moon, Midheaven, and Ascendant at all the important epochs in the life of the late Colonial Secretary. The working out of the more important directional arcs for the same period I can safely leave to the reader whose desire to thoroughly test the claims of Astrology has been sufficiently aroused by the

perusal of these pages. It is at all times easier to dispute than to disprove, and this apparently is the reason for so much that is said, and so little that is shown, against Astrology.

As to the *modus operandi* of planetary influence I conceive that the brain cells are infilled with a nervous pabulum of such delicate nature as to be capable of responding to the finer etheric vibrations instituted by the planets; that the electrostatic condition of the earth's atmosphere at the moment of birth determines the particular mode or modes of vibration to which the individual brain is syntonically responsive; and I could, did space permit, immediately adduce hundreds of instances to show that whenever the same positions or planetary[Pg 126] aspects recur in the heavens as were in existence at the moment of a birth, the individual immediately responds to the excitation, and gives instant evidence of such excitation by actions in agreement with the nature of the planets involved.

[Pg 127]

CHAPTER VI

PLANETARY PERIODS, ETC.

We now come to the point where it will be necessary to explain more fully the various elements with which so far the reader has only been dealing in a more or less mechanical way. It is, of course, of first importance that the student of Astrology should have a correct method, and this has been given as fully as space will permit in the preceding pages. But it is also necessary that one should know why he is doing a thing, as well as how to do it. Henry Ward Beecher once said that if a man turned soil with a spade

knowing why he did it, the work was more effectively done than if he did not know. For this reason it will be convenient for the student to have a general view of the cosmical elements that he employs in his calculations and of the factors that enter into his consideration when studying a horoscope.

For purposes of calculation, the astronomer regards the planets as moving around the Sun in circular orbits at a uniform rate, and the positions thus obtained are called the mean longitudes of the planets. But it is known that the orbit of a planet answers to the functions of an ellipse,[Pg 128] of which the Sun is presumed to occupy one of the foci. Then it becomes necessary to correct the Mean Longitude of the planet by an equation which is called the Centre equation.

Let us make this quite clear. The circular orbit supposed in the first instance is what may be called the Mean Orbit of the planet, as compared with its true orbit, which is elliptical. Similarly, the motion of the planet in the circular orbit is called the Mean Motion, as compared with the true motion, which is variable, being quickest at the perihelion and slowest at the aphelion.

The difference between the Mean longitude and the True longitude is determined by the Anomaly, which is the distance of the planet from its Aphelion, or farthest distance from the Sun. The anomaly is thus L-A, i. e., longitude minus aphelion.

But it will be seen that ellipses may be of greater or less eccentricity, and the equation to centre depends on the eccentricity. This may need a word of explanation. Suppose a circular orbit. Draw the two diameters at right angles to one another; they are of equal length. Now suppose another figure in which the one diameter is longer than the other. The circumference of this figure will be an ellipse. The greater diameter is called the Major Axis, and the diameter at right angles to it is the Minor Axis. The proportion of one to the other axis determines the amount of eccentricity. Twice the eccentricity gives the equation to centre, and to reduce this to degrees and minutes of a circle it has to be multiplied by the chord of 60 degrees, which is 57°·29578. This gives the maximum

equation to centre when the planet is 3 signs or 90 degrees from its aphelion, and therefore on the Minor Axis.

[Pg 129]

The eccentricity of the various planets may be here stated: Mercury, 0.2055; Mars, 0.0931; Jupiter, 0.0482; Saturn, 0.9562; Uranus, 0.9467; Earth, 0.0168; Venus, 0.0068. These quantities undergo a gradual change. Thus it is found that Jupiter, Mars, and Mercury are increasing the eccentricity of their orbits, while Venus, the Earth, and Saturn are reducing it. The orbit of Venus is now almost circular, and it affords an example of the perfect astronomical paradigm.

Thus by the mean motions and the equation to centre the true longitudes of the planets in their heliocentric orbits are obtained. But inasmuch as the orbits of the planets do not lie in the same plane as the Sun, but cross its apparent path at various angles of inclination, a further equation is due to reduce the orbital longitudes of the planets to the ecliptic.

To further reduce these true longitudes into their geocentric equivalents, i. e., as seen from the Earth's centre, we have to employ the angle of Parallax, which is the angle of difference as seen from two different points in space. This will vary according to the relative distances of the bodies from one another. The Moon's longitude is always taken geocentrically. When approximate longitudes are required, the employment of a mean vector, which is equal to half the minor axis of the planet, is found convenient. For the convenience of astronomical students I may here give the constant logarithms of the values of the tangent, which, being added to the logarithm of the tangent of half the distance of the planet from the Sun in longitude, will give the tangent of the complement.

LOGARITHMS

Zaid n. adwan

Neptune, 9.97107; Uranus, 9.95479; Saturn, 9.90858;[Pg 130] Jupiter, 9.83114; Mars, 9.32457; Venus, 9.20812; Mercury, 9.63210.

To these add the bog, tangent of half the angle between the planet and Sun, taken by heliocentric longitude, which call A. Call the result B. For major planets add A and B, and for minor planets subtract B from A. In either case the result will be the angle of longitude between the planet and the Sun as seen from the Earth, and hence its geocentric longitude may be known.

But a more convenient method of obtaining the approximate longitudes of the planets geocentrically is by means of the Planetary Geocentric periods. Thus Uranus has a period of 84 years, after which it returns to the same longitude on the same day of the year and will be further advanced in its orbit by 1° 5′. Saturn has a period of 59 years, after which it comes to the same place in the zodiac and will be further advanced by 1° 53′. Jupiter has a period of 83 years, when it is found to be only 4′ advanced upon its former longitude. Mars' period is 79 years plus an advance of 2° 4′. Mercury's period is also 79 years, and its advance is 5° 32′. Venus has a period of 8 years, when it is further advanced in the zodiac by 1° 32′.

For the calculation of the approximate geocentric longitude of the major planets these periods are very useful, but are of less value in regard to the minor planets Venus and Mercury.

Suppose I want the longitude of Uranus in the year A. D. 827. I have its longitude on the first of January, 1912, in Capricorn 28° 17′. Then 1912-827 gives 1,085 years, which being divided by the period of Uranus (84 years), yields 12 periods and 77 years. The increment[Pg 131] for 1 period being 1° 5′, that for 12 will be 13°, and 77-84ths of 1° 5′ will be another degree, making 14 degrees. As the date is anterior, this amount must be subtracted from its longitude on the first of January, A. D. 827, and in effect we obtain Capricorn 14 degs. 17 mins. as the longitude of Uranus on the first of January, 827, as seen from the Earth.

For the purpose of determining the effects, if any, due to the presence of a planet in its Aphelion, Perihelion, or Node, the following values are given for the year 1800 A. D.:

Planet.	Aphelion.			Perihelion.			Node.		
	S.	°	′	S.	°	′	S.	°	′
Mercury	8	14	21	2	14	21	1	15	57
Venus	10	8	36	4	8	36	2	14	52
Mars	5	2	23	11	2	23	1	18	1
Jupiter	6	11	8	0	11	8	3	8	24
Saturn	8	29	4	2	29	4	3	21	57
Uranus	11	17	21	5	17	21	2	12	51
Neptune	7	12	22	2	12	22	4	9	35

The longitudes of the Aphelia are increased in 100 years by the following quantities: Neptune, 1° 25′; Uranus, 1° 28′; Saturn, 1° 50′; Jupiter, 1° 35′; Mars, 1° 52′; Venus, 1° 43′; Mercury, 1° 34′. These quantities are additive for years after 1800, and subtractive for years before that epoch.

Zaid n. adwan

In the present state of astronomical science it is not certain that these values are absolutely correct. Calculated from the Tables of Kepler, the differences are only slight, but still sufficient to make considerable error in testing for exact conjunctions or ingresses.

Lilly, who predicted the Great Plague and Fire of London some years previous to the event from the ingress of[Pg 132] the Aphelion of Mars to the sign Virgo, evidently made use of the Rudolphine Tables constructed by Tycho and Kepler, and according to these the ingress took place in 1654, while according to more modern Tables it did not take place until 1672. It is probable, however, that the positions of the Aphelia here given will be sufficiently close for all practical purposes.

A word or two may now be said regarding the periodic conjunctions of the planets.

As will be seen from the periods given, five periods of Jupiter are nearly equal to two of Saturn. It is found that the two planets form their conjunctions every 20 years. Thus there was a conjunction in Virgo in 1861, another in Taurus in 1881, and another in Capricornus in 1901. The next will be in Virgo in 1921. The two planets are thus now forming their successive conjunctions in the Earthly Tripicity; but in 1981 will make their mutation conjunction by falling together in the Airy sign Libra.

Uranus and Jupiter form their conjunctions every 14 years. Thus there was a conjunction in Sagittarius in 1900, and there will be another in Aquarius in 1914, another in Aries in 1928, and so on.

The conjunctions of Neptune with the other major planets are necessarily in terms of the periods of the latter, those of Neptune and Uranus being very infrequent, while those with Jupiter will be proportionately more frequent. For the period of Jupiter is only 12 years, while Neptune remains in the same sign for 15 years. The conjunction of Jupiter and Neptune in Cancer in 1907 will be followed by another in Leo in 1919, and this again by another in Virgo in 1932.

Obviously, if the planets by their transits effect anything whatsoever, the double transit of major planets must have[Pg 133] a correspondingly greater effect. The careful student of Astrology will institute a number of tests in order to find what effects are due to the combined action of the planets when in conjunction at transit, and also when in opposition or quadrature. The chief points to be noticed in connection with the transits of the planets are the Midheaven, Ascendant, and the places of the Sun and Moon, as already mentioned in Chapter II of this section.

The ancients also included the places of the Moon's Nodes, and it is usually found that the transit of the South Node over any of the Significators is attended by unfortunate results.

With these observations as a general guide to the cosmical factors involved in the planetary motions, the reader will be able to take a more intelligent interest in the foundations of his study than is the usual case from the pursuit of the subject by rule-of-thumb methods.

When we come to the consideration of the Moon as a cosmical factor we are face to face with one of the most difficult and evasive problems. For many centuries astronomers grappled with this inconstant factor with small success, and at the present day the problems attaching to the vagaries of lunar motion are in anything but a satisfactory condition. Prior to the time of Ptolemy nothing was known of the Moon except that it had a certain mean motion and formed its syzygies at definite periods, the mean values of which were very closely known. But certainly nothing was known regarding the inequalities of motion which are found to exist. Ptolemy discovered the equation due to the action of the Sun upon the Moon in its orbit. This is called the Evection. Tycho later discovered that a further equation was due to the disturbance caused by the Sun along the vector. Both these equations[Pg 134] were employed by Kepler. But of these, later astronomers have added one after another equation, going so far as to employ the action due to Venus and Jupiter, while ignoring that due to the

action of the other planets upon the Moon. Buckhardt, whose formulae were used in the calculation of the Nautical Almanac for many years, employs no less than 37 equations of the Moon's mean longitude. Indeed, the whole business has become farcical. The fact is that only three of these equations are necessary in order to obtain the Moon's true place in the ecliptic at any time, and for the syzygy only one equation is necessary. The trouble has arisen from the fact that the eccentricity of the Moon's orbit has been wrongly estimated, and most of these equations now employed by astronomers are effectual only in correcting this false estimate. Kepler gives the maximum equation to centre as 4° 59′ 59″, while modern astronomers have given it as 6° 18′ 28″. Neither of these is quite correct, though Kepler is much nearer the truth.

Another problem in connection with the Moon that has puzzled astronomers for a long time and is still in the region of experimental science is what is known as the Secular equation. It is found that by taking the present mean motion of the Moon and applying the various equations, found necessary to bring the calculations into line with observations of the Moon's position in the zodiac, a considerable difference is found to exist between the calculated place of the Moon and its recorded position at the time of ancient eclipses. According to our modern Tables, ancient eclipses happened sooner than they should have done, or, in other words, the Moon was more advanced in its orbit than our Tables require. The inference is that the Moon was formerly moving quicker in a smaller orbit[Pg 135] than now, or conversely, the Moon is now receding and getting farther from the Earth. Consequently its action on the tides must be diminishing, and also its action on the equatorial mass of the Earth, which is considered to be the chief factor in the production of what is called the Precession of the Equinoxes. Yet whereas by one statement the disturbance due to the Moon is diminishing, another statement shows that the Precession of the Equinoxes is increasing! **Voila le debacle.**

All these anomalies and contradictions are due, as I shall show in my new Tables and Thesis, to the importation of false factors into the problem of the Moon's motion, which,

zain.adwan

in fact, is extremely simple, perfectly regular, and affected only by its anomaly or distance from the aphelion and, where the time equation is employed, by the increase of radius. Jupiter and Venus have no more action on the Moon than have Mars and Saturn, in fact none at all, and the only body that has any action upon the lunar orb is the Sun, which it exerts indirectly through its action on the Earth.

These problems need not, however, vex the minds of the student of Astrology. It is sufficient for him that he has the place of the Moon calculated for him in the ephemeris reduced from the Nautical or other official Almanac. It is important, however, that he should know that such problems exist.

Sir Isaac Newton was first led to the subject of Astronomy by his thoroughness and scientific propensity. He studied Astrology, and proceeded to the study of Astronomy the better to understand and deal with the problems that the predictive science presented. For it is to be observed that Astrology in his day was entirely in the hands of astronomers, who calculated their own ephemeri[Pg 136]des and pursued the higher methods of astrological calculation as presented in my "Profnostic Astronomy." Kepler avowed himself to be convinced of the truth of the science of Astrology, and showed himself to be a competent critic as much by his understanding of the astronomical problems involved as by his marvellous forecast of the rise and fall of Wallenstein. Tycho, his colleague and collaborator, also a great astronomical discoverer, was a professed Astrologer, and added to his stipend by the calculation of horoscopes. Astrology is quite a reputable study, and needs but to be emancipated from the service of a horde of half-educated plagiarists and parasites in order to take its place once more among subjects of serious consideration by the learned. Astronomy is interesting, but to be made useful it must find interpretation in terms of our daily life and common needs. It is in this connection that Astrology has played Cinderella since the days of official science. The day is not far off when it will come into its own.

[Pg 137]

CHAPTER VII

REVOLUTIONS, ECLIPSES, INGRESSES, ETC.

Beyond the various time measures and indicators mentioned in Section IV, Chapter II, there are others which have a certain reputation among astrological students. The chief of these, and one that has been in vogue for many centuries, is the

Solar Revolution,

or Birthday Figure, as it is sometimes called. It consists in a map of the heavens for the return of the Sun to the exact zodiacal position that it held at birth, and this sidereal revolution is made the basis of an annual forecast of the general trend of affairs in the life of the subject. To find the time of the Sun's return to its own place in the zodiac is, of course, a simple matter of proportion from the ephemeris for the current year. This is effected by comparing the radical or birthplace of the Sun with the longitude of the Sun in the Ephemeris on the anniversary day, which will give the increment more or[Pg 138] less required to be equated. Then with this difference of the two positions of the Sun (a) at birth and (b) at noon of the anniversary, find the diurnal proportional logarithm and subtract from this the logarithm for the Sun's motion in 24 hours. The result will be the logarithm for the hours and minutes from Noon at which the Sun was in the exact position it held at the birth. Thus you have the time of the solar return, and all that is necessary is to erect a horoscope for this time and set the planets in the figure.

Then, if the benefic planets are in elevation and the Lord or Ruler of the Ascendant is well placed and aspected, there will be commensurate results, and a beneficial year may be predicted; but if, on the contrary, the malefic planets are elevated and the ruler of the

zain.adwan

horoscope is badly aspected, the year ensuing will be fraught with many troubles and vexatious events.

But inasmuch as the time-factor is here the return of the Sun to its radical place, chief attention must be paid to the aspects of the Sun, and conclusions agreeable to the nature of the afflicting planets or those that favourably aspect the luminary may be made accordingly.

As regards the time at which events signified by the aspects may be expected to transpire, I have found that they usually occur during the transit of the Sun over the places of the planets in the annual horoscope. Thus a person born in August may have the Sun in the annual horoscope in square aspect to Saturn, the Sun being in Leo and Saturn in Taurus. Then the evil signified by the aspect of Saturn to the Sun would transpire about the date that the Sun passed the opposition of Saturn in the sign Scorpio some time in November, or again in May of the following year when the Sun [Pg 139]was in conjunction with the place of Saturn in the horoscope for the Solar return.

Events that are benefic in nature may be produced from the transit of the Sun over the places of the benefics in the Solar figure, or over the good aspects of the planet which in the annual horoscope gives promise of benefit.

In similar manner the return of the Moon to its own place may be taken as a monthly guide to the nature of ensuing events, but it is to be observed that the Moon’s place cannot be taken with the same degree of accuracy as that of the Sun, owing to the varied acceleration of the Moon from hour to hour. The Nautical Almanac gives this hourly acceleration, so that by means of it the Moon’s longitude can be arrived at with great accuracy for any time of the day, but the cheaper ephemerides do not contain more than the longitude for noon and midnight. The student will find, however, that the general purposes of a Lunar horoscope may be served with sufficient accuracy from this source if chief regard be had to the aspects of the Moon at its return and not to the mundane positions of the planets.

Arguing from analogy, one would suppose that a similar horoscope could be made for the return of any of the planets to their radical places, but until we have a popular publication in which the planets' places are given with a greater degree of accuracy than at present, we cannot pretend to indicate the true time of the revolutions of these bodies.

Another means of prognosis to which some astrologers have attached considerable importance is what is known as

The Synodical Revolution.

This consists of a horoscope set for the time of the Moon's return to the same distance from the Sun that it held at[Pg 140] birth, which distance is called the elongation. This measure is based upon the relative motions of the Sun and Moon in the zodiac after birth. Thus if the mean motion of the Sun for one day be taken as 59′ and that of the Moon as 13° 11′, then the mean elongation of the Moon will be 12° 12′. But the Sun and Moon are both subject to a variation from the mean motion, and thus the elongation of the Moon is an inconstant quantity. The only means of effecting the calculation, therefore, is by reference to the ephemeris for the year of birth. Then, having the Moon's radical elongation, the successive dates at which this elongation is repeated are to be noted, and each of them is accounted as one year of life. Thus for the 20th year of life one must count 19 synods or conjunctions of the Sun and Moon after birth, and thereafter proceed to fix the date after the last synod at which the Moon's elongation is the same as that of birth. This idea seems to give grounds for the ancient belief in effects attaching to the Moon's age. For the Moon's age denotes the distance of the Moon from the last conjunction with the Sun, and if a person was born on the tenth day of the Moon, then every tenth day of the Moon in successive revolutions will be of importance, since the Moon will be in the same relations with the Sun as at birth. The aspects that the Moon bears to the other celestial bodies at these times is held to be a guide to the nature of succeeding events. But more attention is paid to such horoscopes thus calculated wherein the Moon falls on the place of any of the planets at birth.

Ingresses

are of two kinds, mundane and zodiacal. A mundane ingress is made when a planet in the heavens comes to[Pg 141] the cusp of one of the Houses in the horoscope of birth—that is to say, to the degree of the zodiac which held the cusp of such House. Thus if the 8th degree of the sign Aquarius were on the cusp of the 2nd House of the horoscope and Saturn in the heavens made transit of that degree of the zodiac, then the Ingress of Saturn to the 2nd House would be effected and would be followed by a period of considerable financial stress. Similarly with other planets in the horoscope. Each will make its periodical transit through the several Houses of the horoscope of birth, and these will be attended by events in terms of the nature of the planet, the House it transits and its affections at birth.

Zodiacal ingresses are those that are made by the planets into the signs of the zodiac successively, and it is held that a change in the trend of affairs will take place in that department of the life ruled by the House wherein that sign is placed at birth. This, however, appears to be an extension of the former kind of ingress, and should be taken with some reserve. Certainly it will be found that very marked effects are due to the transits of the planets through the Houses of the horoscope, and if the aspects of these planets in the ephemeris are taken into account, it will be found that a very accurate basis for a forecast of the various incidents of individual life is thereby afforded.

In this connection the periodical synods of the planets should be observed, for it is evident that if we ascribe an influence to the transit of Saturn we must set a still more important value upon the transit of that planet when in conjunction or opposition with any other body in the heavens. Thus the planets Mars and Saturn form their conjunctions in successive signs after an interval of about two[Pg 142] years, during which period it may be said that the effects of the last conjunction are in play. Thus Saturn and Mars formed their last conjunction in August, 1911, in the sign Taurus, and, according to the

position of that sign in various horoscopes, effects more or less detrimental and disturbing would be experienced during the course of two years after that date.

Jupiter's period of 12 years will be watched with interest by those who are studying the effects due to its action, for it passes through one sign or one House every year on an average, and therefore constitutes a good chronocrator or time-marker. But Jupiter can effect little for good if at the time of its transit it is afflicted in the heavens by the adverse aspect or conjunction of another planet. Similarly, Saturn or Uranus or Neptune has to be judged according to its condition and aspects at the time of transit or ingress.

Eclipses,

whether of the Sun or Moon, are significant of evil according to their positions and aspects in the horoscope. For if an eclipse of the Sun happens it will afflict male members of the family, and an eclipse of the Moon will denote evil to female members. Eclipses falling in the sign occupying the 10th or 4th Houses will afflict the parents, and those which fall in the 3rd House will similarly affect collateral relatives, such as brothers and sisters, according to the sex indicated.

The effects of eclipses last for eighteen months, and will be great or small according to the magnitude of the eclipse and considerations due to aspects. When falling on the places of benefic planets or those well aspected in the[Pg 143] horoscope, the eclipse will portend good arising out of some catastrophe or bereavement. But when falling on the places of the malefics, or on places in the horoscope that are badly aspected by the planets at birth, they portend nothing but evil.

Falling in other parts of the figure, they are not of such significance, but generally it may be said that eclipses have a detrimental effect on such affairs as are governed by the House wherein the eclipse falls.

It has been said that unless an eclipse is visible in that part of the world where the subject was born, it will have no effect upon his health or fortunes. But this cannot be the case,

for then those planets that are beneath the horizon at the time of birth could with equal reason be exempt from any share in our consideration, whereas, on the contrary, we know full well that in whatever part of the circle the planets may be situated at the moment of birth they will affect the life and fortunes in equal degree, but especially such department of the life as may be ruled by the House a planet occupies.

The following is a list of the visible eclipses that will be witnessed in Great Britain during the next ten years:

1914.—12th March, Moon eclipsed in the third hour of the morning, nearly total.
21st August, the Sun eclipsed about noon, two-thirds of the disc eclipsed. Total in Sweden and Norway.

1916.—9th January, Moon sets in contact with the shadow.
3rd February, the Sun sets about half eclipsed. Total across the Atlantic.
15th July, Moon eclipsed about three-quarters of its disc in the fifth hour of the morning.

1917.—8th January, Moon eclipsed in the eighth hour of the morning, just before sunrise. Total.
4th July, Moon totally eclipsed in the eleventh hour of the evening.
28th December, Moon begins to be eclipsed just before setting.

1919.—7th November, in the twelfth hour at night the Moon is partially eclipsed.

zain.adwan

22nd November, the Sun has one-fifth of its disc obscured near sunset. Annular in the South Atlantic.

1920.—3rd May, Moon totally eclipsed in the second hour of the morning. 10th November, Sun sets half eclipsed.

1921.—8th April, in the ninth hour of the morning the Sun is eclipsed, about five-sixths of the disc being obscured. Annular eclipse in the north. 16th October, the Moon has five-sixths of its disc overshadowed at eleventh hour of the evening.

1922.—28th March, Sun eclipsed in the third hour of the afternoon, about one-sixth being obscured. Annular in Africa.

The years 1805 and 1917 are great eclipse years, for in both those years there are no less than seven eclipses. From like causes we argue like effects, and therefore we may anticipate a great convulsion in the political world during the year 1917 and thereafter. At that time Mars and Saturn will form their conjunction in the sign Leo together with Neptune, and these successive conjunctions of the three major planets cannot fail to produce great[Pg 145] mutations, more especially in those countries that are ruled by the sign Leo.

So far as individual horoscopes are concerned the effects of these conjunctions and the eclipses which fall in the sign Capricornus and Cancer must be judged by the particular

zaid n. adwan

Houses of the horoscopes in which they occur. The general effects due to any eclipse or conjunction of the larger planets are distributed and find their expression through individual horoscopes, the influence filtrating as it were through a variety of channels for the ultimate purpose of human evolution and government.

Thus by many lines of evidence the patient student may confirm his belief in the influence of the stars in human life, which involves the yet higher concept of the government of humanity by the greater Intelligences according to preordained laws, divine in their origin and cosmical in their expression. To this concept as a final expression of faith and of scientific experience we must eventually submit our beliefs and opinions, and haply our willing compliance.

Transcriber's Note:

This e-text is based on the 1920 edition. Punctuation errors have been tacitly corrected. The Table of Contents has been completed to match the text. Inconsistent hyphenation and spelling (e.g., 'every-day'/'everyday'; 'formulæ'/'formulae') have been retained. Large tables have been split and rearranged.

The following typographical errors have been corrected:

p. 6: 'sublinary' → 'sublunary'; 'towhich' → 'to which'
p. 62: 'Shakspeare' → 'Shakespeare'
p. 107: 'intuite' → 'intuit'
p. 132: 'Sagitarius' → 'Sagittarius'
p. 135: 'Viola' → 'Voila'

*** END OF THE PROJECT GUTENBERG EBOOK ASTROLOGY: HOW TO MAKE AND READ YOUR OWN HOROSCOPE ***

Updated editions will replace the previous one—the old editions will be renamed.

Creating the works from print editions not protected by U.S. copyright law means that no one owns a United States copyright in these works, so the Foundation (and you!) can copy and distribute it in the United States without permission and without paying copyright royalties. Special rules, set forth in the General Terms of Use part of this license, apply to copying and

distributing Project Gutenberg™ electronic works to protect the PROJECT GUTENBERG™ concept and trademark. Project Gutenberg is a registered trademark, and may not be used if you charge for an eBook, except by following the terms of the trademark license, including paying royalties for use of the Project Gutenberg trademark. If you do not charge anything for copies of this eBook, complying with the trademark license is very easy. You may use this eBook for nearly any purpose such as creation of derivative works, reports, performances and research. Project Gutenberg eBooks may be modified and printed and given away—you may do practically ANYTHING in the United States with eBooks not protected by U.S. copyright law. Redistribution is subject to the trademark license, especially commercial redistribution.

START: FULL LICENSE

THE FULL PROJECT GUTENBERG™ LICENSE

PLEASE READ THIS BEFORE YOU DISTRIBUTE OR USE THIS WORK

To protect the Project Gutenberg™ mission of promoting the free distribution of electronic works, by using or distributing this work (or any other work associated in any way with the phrase "Project Gutenberg"), you agree to comply with all the terms of the Full Project Gutenberg License available with this file or online at www.gutenberg.org/license.

Section 1. General Terms of Use and Redistributing Project Gutenberg electronic works

1.A. By reading or using any part of this Project Gutenberg electronic work, you indicate that you have read, understand, agree to and accept all the terms of this license and intellectual property (trademark/copyright) agreement. If you do not agree to abide by all the terms of this agreement, you must cease using and return or destroy all copies of Project Gutenberg electronic works in your possession. If you paid a fee for obtaining a copy of or access to a Project Gutenberg electronic work and you do not agree to be bound by the terms of this agreement, you may obtain a refund from the person or entity to whom you paid the fee as set forth in paragraph 1.E.8.

1.B. "Project Gutenberg" is a registered trademark. It may only be used on or associated in any way with an electronic work by people who agree to be bound by the terms of this agreement. There are a few things that you can do with most Project Gutenberg electronic works even without complying with the full terms of this agreement. See paragraph 1.C below. There are a lot of things you can do with Project Gutenberg electronic works if you follow the terms of this

agreement and help preserve free future access to Project Gutenberg electronic works. See paragraph 1.E below.

1.C. The Project Gutenberg Literary Archive Foundation ("the Foundation" or PGLAF), owns a compilation copyright in the collection of Project Gutenberg electronic works. Nearly all the individual works in the collection are in the public domain in the United States. If an individual work is unprotected by copyright law in the United States and you are located in the United States, we do not claim a right to prevent you from copying, distributing, performing, displaying or creating derivative works based on the work as long as all references to Project Gutenberg are removed. Of course, we hope that you will support the Project Gutenberg mission of promoting free access to electronic works by freely sharing Project Gutenberg works in compliance with the terms of this agreement for keeping the Project Gutenberg name associated with the work. You can easily comply with the terms of this agreement by keeping this work in the same format with its attached full Project Gutenberg License when you share it without charge with others.

1.D. The copyright laws of the place where you are located also govern what you can do with this work. Copyright laws in most countries are in a constant state of change. If you are outside the United States, check the laws of your country in addition to the terms of this agreement before downloading, copying, displaying, performing, distributing or creating derivative works based on this work or any other Project Gutenberg work. The Foundation makes no representations concerning the copyright status of any work in any country other than the United States.

1.E. Unless you have removed all references to Project Gutenberg:

1.E.1. The following sentence, with active links to, or other immediate access to, the full Project Gutenberg License must appear prominently whenever any copy of a Project Gutenberg work (any work on which the phrase "Project Gutenberg" appears, or with which the phrase "Project Gutenberg" is associated) is accessed, displayed, performed, viewed, copied or distributed:

This eBook is for the use of anyone anywhere in the United States and most other parts of the world at no cost and with almost no restrictions whatsoever. You may copy it, give it away or re-use it under the terms of the Project Gutenberg™ License included with this eBook or online at www.gutenberg.org. If you are not located in the United States, you will have to check the laws of the country where you are located before using this eBook.

zain.dowan

1.E.2. If an individual Project Gutenberg electronic work is derived from texts not protected by U.S. copyright law (does not contain a notice indicating that it is posted with permission of the copyright holder), the work can be copied and distributed to anyone in the United States without paying any fees or charges. If you are redistributing or providing access to a work with the phrase “Project Gutenberg” associated with or appearing on the work, you must comply either with the requirements of paragraphs 1.E.1 through 1.E.7 or obtain permission for the use of the work and the Project Gutenberg trademark as set forth in paragraphs 1.E.8 or 1.E.9.

1.E.3. If an individual Project Gutenberg electronic work is posted with the permission of the copyright holder, your use and distribution must comply with both paragraphs 1.E.1 through 1.E.7 and any additional terms imposed by the copyright holder. Additional terms will be linked to the Project Gutenberg License for all works posted with the permission of the copyright holder found at the beginning of this work.

1.E.4. Do not unlink or detach or remove the full Project Gutenberg License terms from this work, or any files containing a part of this work or any other work associated with Project Gutenberg.

1.E.5. Do not copy, display, perform, distribute or redistribute this electronic work, or any part of this electronic work, without prominently displaying the sentence set forth in paragraph 1.E.1 with active links or immediate access to the full terms of the Project Gutenberg License.

1.E.6. You may convert to and distribute this work in any binary, compressed, marked up, nonproprietary or proprietary form, including any word processing or hypertext form. However, if you provide access to or distribute copies of a Project Gutenberg work in a format other than “Plain Vanilla ASCII” or other format used in the official version posted on the official Project Gutenberg website (www.gutenberg.org), you must, at no additional cost, fee or expense to the user, provide a copy, a means of exporting a copy, or a means of obtaining a copy upon request, of the work in its original “Plain Vanilla ASCII” or other form. Any alternate format must include the full Project Gutenberg License as specified in paragraph 1.E.1.

1.E.7. Do not charge a fee for access to, viewing, displaying, performing, copying or distributing any Project Gutenberg works unless you comply with paragraph 1.E.8 or 1.E.9.

1.E.8. You may charge a reasonable fee for copies of or providing access to or distributing Project Gutenberg electronic works provided that:

zain.adwan

- • You pay a royalty fee of 20% of the gross profits you derive from the use of Project Gutenberg works calculated using the method you already use to calculate your applicable taxes. The fee is owed to the owner of the Project Gutenberg trademark, but he has agreed to donate royalties under this paragraph to the Project Gutenberg Literary Archive Foundation. Royalty payments must be paid within 60 days following each date on which you prepare (or are legally required to prepare) your periodic tax returns. Royalty payments should be clearly marked as such and sent to the Project Gutenberg Literary Archive Foundation at the address specified in Section 4, "Information about donations to the Project Gutenberg Literary Archive Foundation."

- • You provide a full refund of any money paid by a user who notifies you in writing (or by e-mail) within 30 days of receipt that s/he does not agree to the terms of the full Project Gutenberg™ License. You must require such a user to return or destroy all copies of the works possessed in a physical medium and discontinue all use of and all access to other copies of Project Gutenberg™ works.

- • You provide, in accordance with paragraph 1.F.3, a full refund of any money paid for a work or a replacement copy, if a defect in the electronic work is discovered and reported to you within 90 days of receipt of the work.

- • You comply with all other terms of this agreement for free distribution of Project Gutenberg™ works.

1.E.9. If you wish to charge a fee or distribute a Project Gutenberg™ electronic work or group of works on different terms than are set forth in this agreement, you must obtain permission in writing from the Project Gutenberg Literary Archive Foundation, the manager of the Project Gutenberg™ trademark. Contact the Foundation as set forth in Section 3 below.

1.F.

1.F.1. Project Gutenberg volunteers and employees expend considerable effort to identify, do copyright research on, transcribe and proofread works not protected by U.S. copyright law in creating the Project Gutenberg™ collection. Despite these efforts, Project Gutenberg™ electronic works, and the medium on which they may be stored, may contain "Defects," such as, but not limited to, incomplete, inaccurate or corrupt data, transcription errors, a copyright or

Zaid n. adwan

other intellectual property infringement, a defective or damaged disk or other medium, a computer virus, or computer codes that damage or cannot be read by your equipment.

1.F.2. LIMITED WARRANTY, DISCLAIMER OF DAMAGES - Except for the "Right of Replacement or Refund" described in paragraph 1.F.3, the Project Gutenberg Literary Archive Foundation, the owner of the Project Gutenberg™ trademark, and any other party distributing a Project Gutenberg™ electronic work under this agreement, disclaim all liability to you for damages, costs and expenses, including legal fees. YOU AGREE THAT YOU HAVE NO REMEDIES FOR NEGLIGENCE, STRICT LIABILITY, BREACH OF WARRANTY OR BREACH OF CONTRACT EXCEPT THOSE PROVIDED IN PARAGRAPH 1.F.3. YOU AGREE THAT THE FOUNDATION, THE TRADEMARK OWNER, AND ANY DISTRIBUTOR UNDER THIS AGREEMENT WILL NOT BE LIABLE TO YOU FOR ACTUAL, DIRECT, INDIRECT, CONSEQUENTIAL, PUNITIVE OR INCIDENTAL DAMAGES EVEN IF YOU GIVE NOTICE OF THE POSSIBILITY OF SUCH DAMAGE.

1.F.3. LIMITED RIGHT OF REPLACEMENT OR REFUND - If you discover a defect in this electronic work within 90 days of receiving it, you can receive a refund of the money (if any) you paid for it by sending a written explanation to the person you received the work from. If you received the work on a physical medium, you must return the medium with your written explanation. The person or entity that provided you with the defective work may elect to provide a replacement copy in lieu of a refund. If you received the work electronically, the person or entity providing it to you may choose to give you a second opportunity to receive the work electronically in lieu of a refund. If the second copy is also defective, you may demand a refund in writing without further opportunities to fix the problem.

1.F.4. Except for the limited right of replacement or refund set forth in paragraph 1.F.3, this work is provided to you 'AS-IS', WITH NO OTHER WARRANTIES OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO WARRANTIES OF MERCHANTABILITY OR FITNESS FOR ANY PURPOSE.

1.F.5. Some states do not allow disclaimers of certain implied warranties or the exclusion or limitation of certain types of damages. If any disclaimer or limitation set forth in this agreement violates the law of the state applicable to this agreement, the agreement shall be interpreted to make the maximum disclaimer or limitation permitted by the applicable state law. The invalidity or unenforceability of any provision of this agreement shall not void the remaining provisions.

Zain n. adwan

1.F.6. INDEMNITY - You agree to indemnify and hold the Foundation, the trademark owner, any agent or employee of the Foundation, anyone providing copies of Project Gutenberg™ electronic works in accordance with this agreement, and any volunteers associated with the production, promotion and distribution of Project Gutenberg™ electronic works, harmless from all liability, costs and expenses, including legal fees, that arise directly or indirectly from any of the following which you do or cause to occur: (a) distribution of this or any Project Gutenberg work, (b) alteration, modification, or additions or deletions to any Project Gutenberg work, and (c) any Defect you cause.

Section 2. Information about the Mission of Project Gutenberg

Project Gutenberg is synonymous with the free distribution of electronic works in formats readable by the widest variety of computers including obsolete, old, middle-aged and new computers. It exists because of the efforts of hundreds of volunteers and donations from people in all walks of life.

Volunteers and financial support to provide volunteers with the assistance they need are critical to reaching Project Gutenberg's goals and ensuring that the Project Gutenberg collection will remain freely available for generations to come. In 2001, the Project Gutenberg Literary Archive Foundation was created to provide a secure and permanent future for Project Gutenberg and future generations. To learn more about the Project Gutenberg Literary Archive Foundation and how your efforts and donations can help, see Sections 3 and 4 and the Foundation information page at www.gutenberg.org.

Section 3. Information about the Project Gutenberg Literary Archive Foundation

The Project Gutenberg Literary Archive Foundation is a non-profit 501(c)(3) educational corporation organized under the laws of the state of Mississippi and granted tax exempt status by the Internal Revenue Service. The Foundation's EIN or federal tax identification number is 64-6221541. Contributions to the Project Gutenberg Literary Archive Foundation are tax deductible to the full extent permitted by U.S. federal laws and your state's laws.

The Foundation's business office is located at 41 Watchung Plaza #516, Montclair NJ 07042, USA, +1 (862) 621-9288. Email contact links and up to date contact information can be found at the Foundation's website and official page at www.gutenberg.org/contact

zaid n. adwan

Section 4. Information about Donations to the Project Gutenberg Literary Archive Foundation

Project Gutenberg™ depends upon and cannot survive without widespread public support and donations to carry out its mission of increasing the number of public domain and licensed works that can be freely distributed in machine-readable form accessible by the widest array of equipment including outdated equipment. Many small donations ($1 to $5,000) are particularly important to maintaining tax exempt status with the IRS.

The Foundation is committed to complying with the laws regulating charities and charitable donations in all 50 states of the United States. Compliance requirements are not uniform and it takes a considerable effort, much paperwork and many fees to meet and keep up with these requirements. We do not solicit donations in locations where we have not received written confirmation of compliance. To SEND DONATIONS or determine the status of compliance for any particular state visit www.gutenberg.org/donate.

While we cannot and do not solicit contributions from states where we have not met the solicitation requirements, we know of no prohibition against accepting unsolicited donations from donors in such states who approach us with offers to donate.

International donations are gratefully accepted, but we cannot make any statements concerning tax treatment of donations received from outside the United States. U.S. laws alone swamp our small staff.

Please check the Project Gutenberg web pages for current donation methods and addresses. Donations are accepted in a number of other ways including checks, online payments and credit card donations. To donate, please visit: www.gutenberg.org/donate.

Section 5. General Information About Project Gutenberg electronic works

Professor Michael S. Hart was the originator of the Project Gutenberg concept of a library of electronic works that could be freely shared with anyone. For forty years, he produced and distributed Project Gutenberg eBooks with only a loose network of volunteer support.

Project Gutenberg eBooks are often created from several printed editions, all of which are confirmed as not protected by copyright in the U.S. unless a copyright notice is included. Thus, we do not necessarily keep eBooks in compliance with any particular paper edition.

Most people start at our website which has the main PG search facility: www.gutenberg.org.

Zaid H. Adwan

This website includes information about Project Gutenberg, including how to make donations to the Project Gutenberg Literary Archive Foundation, how to help produce our new eBooks, and how to subscribe to our email newsletter to hear about new eBooks.

FOREWORD

Of all subjects that have at any time engaged the attention of the world, there is none more ancient than astrology. In the East—where it first arose at a period of very remote antiquity—it still holds sway and in every part of the world (especially among the learned) it reigned supreme until the middle of the seventeenth century. That it not only ruled the daily actions of individuals but swayed the councils of princes, is shown by the records of every nation that has a history (and by none more fully than by that of England); yet the present generation seems never, until quite lately, to have cared to inquire on what basis this belief could have been for so many ages supported. During the past ten years, however—possibly from a reaction growing out of the realism by which we have been so long oppressed—a new interest in these old-world beliefs has sprung up and it is to satisfy that interest that this book (containing the results of many years' study) was written.

Chiromancy and Physiognomy are both based on astrology and are, therefore, quite in place as the second and third parts of a work treating of the influence of the stars. Many of the modern writers on Chiromancy seem disposed to deny its affinity to astrology, with which it is, however, inseparably connected. Dr. Saunders, in the preface to his exhaustive work on Chiromancy and Physiognomy, published in 1671, and dedicated

Zaid n. adwan

to his friend Lilly, the great astrologer, says: "For our more orderly proceeding with the body of this work, it is in the first place necessary to be observed that there are seven planets, named *Stellæ Errantes*—wandering stars—which have each of them its separate character as they are used in astrologie; the which stars have great power over inferior bodies and do, each of them, govern some part or other of man's body and they *especially have their material existence in the hand* and without astrology Chiromancy could not subsist and be subservient to true wisdom."

Now, why, in the face of this and many other equally forcible words among the old-world authorities, do the modern writers try to force their own crude theories upon us? To drag the time-honoured study of Chiromancy into the turmoil of nineteenth-century existence and—by robbing it of its mysticism—to strain it into unison with the realism of modern thought, strikes the earnest student with the same sense of incongruity as would the hanging of a carnival mask over the mystically calm features of an antique statue.

THE
INFLUENCE OF THE STARS

ASTROLOGY

"To doubt the influence of the stars is to doubt the wisdom and providence of God."—TYCHO BRAHE.

CHAPTER I.

That a certain power, derived from æthereal nature, pervades the whole earth, is clearly evident to all. Fire and air are altered by the motions of the æther, and these elements, in their turn, encompassing all inferior matter, vary it, as they themselves are varied, acting equally on earth and water, on plants and animals. The Sun, not only by the change of the seasons, brings to perfection the embryo of animals, the buds of plants and the springs of water, but also, by his daily movement, brings light, heat, moisture, dryness and cold.

The Moon, being of all the heavenly bodies the nearest to earth, has also much influence, and things animate and inanimate sympathise and vary with her. By her changes rivers swell or are reduced, the tides of the sea are ruled by her risings and settings, and animals and plants are influenced as she waxes or wanes. The stars also produce in the ambient [1] many impressions, causing heats, winds and storms, to the influence of which earthly things are subjected. The force of the Sun, however, predominates, because it is more generally distributed; the others either co-operate with

Zaid n. adwan

his power or diminish its effects. The Moon more frequently does this at her first and last quarter; the stars act also in the same way, but at longer intervals and more obscurely than the Moon. From this it follows that not only all bodies which may be already in existence are subjected to the motion of the stars, but also that the impregnation and growth of the seeds from which all bodies proceed are moulded by the quality in the ambient at the time of such impregnation and growth. When, therefore, a person has acquired a thorough knowledge of the stars (not of what they are composed, but of the *influences* they possess), he will be able to predict the mental and physical qualities and the future events in the existence of any one whose actual moment of birth is accurately given to him. But the science of astrology demands great study, a good memory, constant attention to a multitude of different points and much power of deductive judgment; and those persons who undertake to cast horoscopes without possessing these qualities, must necessarily make frequent mistakes in their judgments, which, perhaps, accounts for much of the disbelief which exists as regards the power of astrology; but it is unfair to blame the science for inaccuracies which are only the result of the ignorance of its exponents. No one should attempt to pronounce judgments on the influence of the stars without having first given years of study to the subject; and even then, unless he should have been born under certain influences, [2] he will never become a proficient astrologer.

The practice of observing the stars began in Egypt in the reign of Ammon (about a thousand years before the Christian era), and was spread by conquest in the reign of his successor into the other parts of Africa, Asia, and Europe; but it appears to have been taught in the earliest ages by oral tradition only, for there is no good evidence of its having been reduced to written rules before some years after the first century of the Christian era, when Claudius Ptolemy (who was born and educated in Alexandria) produced a work called *Tetra-biblos*, or *Quadripartite*, being four books of the influences of the stars. In this treatise (translated into English by John Whalley—

Professor of Astrology—in the year of 1786) Ptolemy seems to have collected all that which appeared to him of importance in the science. Another translation of the *Tetra-biblos*, rendered into English from the Greek paraphrase of that work by Proclus, was made in 1822 by J. M. Ashmand and this is, by most people, preferred to the translation made by Whalley. Somewhere between 1647 and 1657, Placidus di Titus, a Spanish monk, published a system of astrology, founded, to a great extent, upon Ptolemy's calculations. This work was printed in Latin and is called the *Primum Mobile*, or *First Mover*, and was translated by John Cooper in 1816; other translations have appeared, but his is the best among them.

The planetary orbs, which the ancients recognised as having the most powerful influence, were seven in number (now known under the Latin names of the principal deities of the heathen mythology), viz.: Jupiter, Saturn, the Sun, Mercury, Venus, Mars and the Moon.

It may be objected that science has long since revealed to us many more planets than the seven known to the ancients; but, in considering a study so mystical as that of astrology, it is better to adhere to the theories of the old-world writers. In the earliest ages almost all the inhabitants of the earth led pastoral lives—were, in fact, merely shepherds—but amongst these shepherds there naturally arose, from time to time, men of superior intelligence, whose imaginations (purified and strengthened by solitude and the constant communion with Nature which grew out of that solitude) led them to the study of those distant lights which they saw, night after night, appear and disappear in the wide expanse of the heavens above them. Of purer lives and more impressionable than we moderns, they were necessarily more open to the influences of nature; and all their thoughts being given to the study of the mysteries by which they felt themselves surrounded, their intuitive perception is likely to be a safer guide on mystical subjects than the scientific conjectures of our day. Besides, as the results produced by their methods were astoundingly correct, why should we imagine ourselves capable of

bettering their theories? Jupiter, Saturn, Mars and Mercury are *still* the most important planets, whilst the Moon (though so small) has a more subtle influence in consequence of her nearness to us; whilst of the Sun's power over us and the whole creation there can, of course, be no question. Each of these seven planets is in the ascendant once during the space of the twenty-four hours forming the day and night; and according to the junction of two or more planets under which a person is born, his outward appearance, character and fate, will be influenced. The sign of the zodiac, too, under which a child comes into the world, possesses a power to produce a particular form of body and mental inclination, always, however, *subject to the influence* of the seven planets.

It must also be borne in mind that the planets dominating the lives of both parents would, to a certain extent, have an influence not only during the pre-natal period of our existence, but also in arresting or hurrying forward the moment of our advent into life. The father's influence is strong at the moment of conception; the mother's during the whole period of pre-natal existence. In this way we can account for the resemblance between parents and children, and also for the physical and mental qualities which we see constantly reproduced through a long line of ancestry. It is rarely that one planet is the sole influence of a life, for the child at birth may, and more generally does, receive influences from several planets, and some not those of the father or mother; and thus we can account for the innumerable differences of mind and body to be found among members of the same family.

For the benefit of those who object that there is too great a leaning to what they would call "the dangerous doctrine of fatalism" in these old-world beliefs, it may be well to quote a few reassuring words from a very able and voluminous writer on these subjects, Dr. Richard Saunders, who modestly styles himself on the title-page of his learned work (published in 1671) student in astrology and physic. "The stars," he says, "have such an influential power over us that we act by them and, though *they are but second causes*,

their influences do so necessitate us that we cannot avoid their fatality, *unless* we have recourse to the First Cause which governs this all." In other words, though the stars influence us, God rules the stars.

CHAPTER II.

THE ALPHABET OF ASTROLOGY

The Science of Astrology consists of four branches, namely, *Mundane Astrology*, which is the art of foreseeing, by the aspect of the stars, at certain periods, the events likely to happen to nations, such as pestilences, wars, inundations and earthquakes; *Atmospherical Astrology*, which is the art of foreseeing, by the positions of the heavenly bodies, the quality of the weather at any particular time or place; *the Casting of Nativities*, or the art of foretelling, from the position of the stars at the moment of birth, the fate and character of the native; and *Horary Astrology*, or the art of foreseeing, by the positions of the heavens at the moment, the result of any business or circumstance.

As the two former branches are treated in the astrological almanacks issued every year by Zadkiel, Raphael, Orion, and others, it is needless to go into them; but as the casting of nativities and the answering of horary questions require individual treatment, the working of these two branches of astrology (*after the ancient methods*) shall be described as clearly as possible.

Before the student can do anything in astrology he must master its alphabet—that is, he must make himself thoroughly acquainted with the symbols used to represent the planets, the signs of the zodiac and the aspects.

Zaid H. adwan

The planets recognised by the ancient astrologers are, as we have seen, seven in number, and are as follows, with their symbols:—Saturn, ♄ ; Jupiter, ♃ ; Mars, ♂ ; Sol, ☉ ; Venus, ♀ ; Mercury, ☿ ; Luna, ☽ .

There are also the Dragon's Head, thus symbolised, ☊; and the Dragon's Tail, ☋. These are neither planets nor signs of the zodiac, nor constellations, but are only the nodes or points where the ecliptic is crossed by the Moon. One of these points looks northward, where the Moon begins her northern latitude, and the other points southward, where she commences her south latitude. The head of the Dragon is considered of a benevolent nature; the tail of the Dragon is of evil tendency.

There are also the twelve signs of the zodiac, which are as follows, with their symbols:—

NORTHERN.		SOUTHERN.	
♈	Aries	♎	Libra
♉	Taurus	♏	Scorpio
♊	Gemini	♐	Sagittarius
♋	Cancer	♑	Capricorn
♌	Leo	♒	Aquarius
♍	Virgo	♓	Pisces

Through these twelve signs the planets continually move, and are ever in one or other of them.

Zain n. adwan

They are divided into *north* and *south*. The first six, from Aries to Virgo, are *northern*; the latter six, from Libra to Pisces, are *southern*; this is because the Sun and planets when in the first six are north of the equator, and when in the last six they are south of that line.

Each point of the zodiac rises and sets once every twenty-four hours, occasioned by the earth's revolution on its axis once every day; therefore, when any given point is *rising*, the opposite point must be *setting*. [3]

As the zodiac consists of 360 degrees from the first point of Aries until we come to that point again, and as these are divided into twelve portions or signs, they must consist of 30 degrees each.

The aspects are five in number; they represent certain positions which the planets bear to each other as they move through the signs of the zodiac; they are as follows, with their symbols:—

☌ Conjunction, when two planets are in the same place, viz., in same degree of the same sign.

⚹ Sextile, when they are 60 degrees or two signs apart.

□ Square, when they are 90 degrees or three signs apart.

△ Trine, when they are 120 degrees or four signs apart.

☍ Opposition, when they are 180 degrees or six signs asunder.

The conjunction (☌) is rather a position than an aspect, as planets can hardly be said to aspect each other when they are in the same place. When Saturn is in the first degree of Aries, and any planet in the same degree of that sign, they are said to be in conjunction; this is good or evil, according to the nature of the planets thus posited.

zaid n. adwan

The Trine (△) is the most powerful of all the good aspects.

The Sextile (⚹) is favourable.

The Square (□) is evil.

The Opposition (☌) is also very evil.

There are several other aspects (sometimes called the "modern aspects") invented by Kepler; but as they only appear to complicate what is at best a very intricate study, it is best to ignore them and adhere in this, as in the matter of the planets, to the old methods.

CHAPTER III.

CONCERNING THE SIGNS OF THE ZODIAC

The zodiac is a band or belt, measuring about 14 degrees in breadth, but, as Venus sometimes appears to have more than her real latitude, it is more correctly considered to be 18 degrees in breadth. The *ecliptic*, or path of the Sun, passes exactly through the centre of the zodiac, longitudinally.

The ancients divided the zodiac into *ten signs*—Libra being omitted altogether, Virgo and Scorpio being merged into one, thus: Virgo-Scorpio. This accounts for the similarity of their symbols, ♍♏.

Ptolemy divides the zodiac into twelve equal parts, of 30 degrees each. He says: "The beginning of the whole zodiacal circle (which in its nature as a circle can have no other beginning or end capable of being determined) is, therefore, assumed to be the sign Aries, which commences at the vernal equinox in March."

One of the many objections urged against Ptolemy's system of astrology is that the signs are continually moving from their positions; but Ptolemy seems to have been aware of this motion of the signs, and has met this objection by what he says in the twenty-fifth chapter of the first book of the *Tetra-biblos*, where he makes it clear that the respective influences he ascribes to the twelve signs were considered by him to belong rather to the *places* they occupied in the ambient than to the stars of which they are composed; and he especially speaks of the *ambient* as producing the effects attributed to the respective signs of the zodiac when in the ascendant in a nativity; thus his astrology is just as applicable to modern astronomy as it was to his own.

The signs have been divided into four *triplicities*, thus: *fiery* ♈, ♌, ♐; *earthy*, ♉, ♍, ♑; *airy*, ♊, ♎, ♒; and *watery*, ♋, ♏, ♓.

The *bicorporal*, or double-bodied, signs are ♊, ♓, and the first half of ♐. The *fruitful* signs are ♋, ♏, ♓; the barren signs are ♊, ♌, and ♑.

These descriptions are useful in showing the modifications brought to bear (by the sign ascending) on the planet's influence. But, when no planets are in or near the ascendant at birth, the following descriptions of the temperament and form of body produced by each sign ascending at birth should be used.

Aries (♈) is a hot and fiery sign and produces a lean body, spare and strong, large bones, grey eyes, with a quick glance and sandy or red-coloured hair. The temper is violent. It governs the head and face; its colour is white.

Taurus (♉) differs greatly, in its effects, from the preceding sign; it is cold and dry, and gives a broad brow and thick lips. A person born under it is melancholy and slow

to anger but, when roused, furious and difficult to be appeased. It governs the neck and throat; its colour is red.

Gemini (♊) is in nature hot and moist and produces a person of straight, tall body, sanguine complexion, brilliant eyes and light brown hair. The temperament of those born under Gemini is lively and the understanding good. This sign governs the arms and shoulders; its colours are red and white.

Cancer (♋) is by nature cold and moist; it produces a native fair and pale, short in stature, with a round face, sand-coloured brown hair and grey eyes. Those born under it are phlegmatic, indolent and gentle tempered. Women born under this sign generally have many children. It governs the breast and stomach; its colours are green and russet-brown.

Leo (♌) is a fiery, hot and dry sign. When it rises at birth without any planet being near the ascendant, the native will be of tall stature, with yellow hair, ruddy complexion and oval face, and he will have a quick glance and a strong voice. It governs the heart, the back and the neck; its colours are red and green.

Virgo (♍) is an earthy, cold, barren, feminine sign. When it ascends, it shows a well-formed body, slender and tall, straight, dark-brown hair and a round face. The mind of the native is ingenious, but rather inconstant. It governs the belly; its colour is black speckled with blue.

Libra (♎) is an aërial, sanguine, masculine, hot and moist sign. Rising at birth it produces a well-made body, with long limbs, an oval and beautiful face, sanguine complexion, straight flaxen hair and grey eyes. Those born under it are courteous, just and honourable. It governs the loins; and the colours under its rule are black, crimson and tawny.

Zaid H. adwan

Scorpio ( ) is a moist, phlegmatic, feminine sign. It gives a strong, corpulent body, low stature, thick legs, hair growing low on the forehead and heavy eyebrows. Those born under this sign are reserved, thoughtful, subtle and malicious. It governs the lower parts of the body; the colour under its rule is brown.

Sagittarius ( ) is a fiery, masculine sign. The person born under its rule is handsome, with a rather long face and features, chestnut hair, inclined to baldness and ruddy complexion; the body strong and active. Those born under this sign are fond of field sports, are good riders, and are lovers of animals. They are kindly, generous and careless of danger. This sign governs the thighs and hips, and rules yellow and green.

Capricorn ( ) is an earthy, cold, dry, feminine sign. It produces a person of slender stature, with a long neck, narrow chest and dark hair. The mind is quick, witty and subtle. It governs the knees and hams and, in colours, it rules black or dark brown.

Aquarius ( ) is an airy, moist, masculine sign. In a nativity where no planets are in or near the ascendant, it would produce a person of a well-set, strong body, long face and delicate complexion, with brown hair. It governs the legs and ankles and rules the sky-colour or blue.

Pisces ( ) is a watery, cold and feminine sign. It produces a person of short stature and fleshy body, with a rather stooping gait. Those born under its influence are indolent and phlegmatic. It governs the feet and toes and presides over the pure white colour. It is needful to remember the colours belonging to the signs, as they are especially useful in horary questions.

CHAPTER IV.

OF THE NATURES OF THE SEVEN PLANETS AND OF THEIR ESSENTIAL AND ACCIDENTAL DIGNITIES

Of the seven planets Jupiter and Venus, because of the heat and moisture predominant in them, are considered by the ancients as benefics or causers of good. The Moon is so considered for the same reasons, though in a less degree.

Saturn and Mars are causers of evil or malefic; the first from his excess of cold, and the other from his excess of heat. The Sun and Mercury are deemed of common influence—that is, either of good or evil, according to the planets with which they are connected.

The planets have particular familiarity with certain places in the zodiac by means of parts designated as their houses, and also by their *triplicities*, *exaltations* and *terms*.

The nature of their familiarity by *houses* is as follows:—

Cancer and Leo are the most northerly of all the twelve signs; they approach nearer than the other signs to the zenith of this part of the earth, and thereby cause warmth and heat; they are consequently appropriated as houses for the two principal and greater luminaries; Leo for the Sun, as being masculine; and Cancer for the Moon, as being feminine.

Saturn, since he is cold and inimical to heat, moving also in a superior orbit most remote from the luminaries, occupies the signs opposite to Cancer and Leo; these are Aquarius and Capricorn, and they are assigned to him in consideration of their cold and wintry nature.

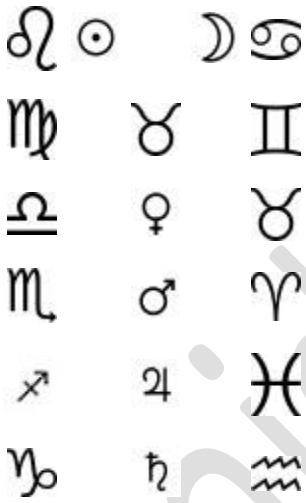
Jupiter has a favourable temperament, and is situated beneath the sphere of Saturn; he, therefore, occupies the next two signs, Sagittarius and Pisces.

Mars is dry in nature and beneath the sphere of Jupiter; he takes the next two signs, of a nature similar to his own, viz., Aries and Scorpio, whose relative distances from the houses of the luminaries are injurious and discordant.

Venus, possessing a favourable temperament, and, placed beneath the sphere of Mars, takes the next two signs, Taurus and Libra. These are of a fruitful nature and preserve harmony by the sextile distance; this planet is never more than two signs distant from the Sun.

Mercury never has greater distance from the Sun than the space of one sign, and is beneath all the other planets; hence he is nearest to both luminaries, and the remaining two signs, Gemini and Virgo, are allotted to him.

The "houses" of the planets are readily shown by the following table. It is exactly the same as that found in the mummy-case of the Archon of Thebes, in ancient Egypt, as may be seen at the British Museum:



It will be seen, at once, from this table that the Sun and Moon have each only one house assigned them. All planets are most powerful in that sign which constitutes one of their houses. Planets receive detriment in the signs opposite to those of their houses. Thus, Saturn would receive detriment in Cancer and Leo, which are the signs opposite to his houses, Capricornus and Aquarius. There are some signs in which the planets are found to be very powerful, though not to the same extent as when in their own houses; these are called the "exaltations" of the planets, and the signs opposite to these are those in which they receive their "fall" when they are considered to be weak in power. Saturn

Zaid n. adwan

has his exaltation in Libra; his "fall" would therefore be in Aries. He governs the airy triplicity, which is composed of the signs Gemini, Libra and Aquarius by day, and in all the twelve signs he has these degrees (zodiacal signs) allotted him by Ptolemy for his Terms:

In Aries	27, 28, 29, 30.
In Taurus	23, 24, 25, 26.
In Gemini	22, 23, 24, 25.
In Cancer	28, 29, 30.
In Leo	1, 2, 3, 4, 5, 6.
In Virgo	19, 20, 21, 22, 23, 24.
In Libra	1, 2, 3, 4, 5, 6.
In Scorpio	28, 29, 30.
In Sagittarius	21, 22, 23, 24, 25.
In Capricornus	26, 27, 28, 29, 30.
In Aquarius	1, 2, 3, 4, 5, 6.
In Pisces	27, 28, 29, 30.

The meaning of which is that if Saturn should rise in any of these degrees it is a sign that he is not void of essential dignities; or, if he is posited in any of the following degrees (which he is allowed for his Face or Decanate) he is still not devoid of dignities. This is to be understood of all the planets.

Saturn is allotted for his Face these degrees:

In Taurus	21, 22, 23, 24, 25, 26, 27, 28, 29, 30.
In Leo	1, 2, 3, 4, 5, 6, 7, 8, 9, 10.
In Libra	11, 12, 13, 14, 15, 16, 17, 18, 19, 20.

zaid n. adwan

In Sagittarius	21, 22, 23, 24, 25, 26, 27, 28, 29, 30.
In Pisces	1, 2, 3, 4, 5, 6, 7, 8, 9, 10.

Jupiter has his exaltation in Cancer and his fall in Capricornus. He rules the fiery triplicity, Aries, Leo and Sagittarius, by night.

He has these degrees allotted for his Terms:

In Aries	1, 2, 3, 4, 5, 6.
In Taurus	16, 17, 18, 19, 20, 21, 22.
In Gemini	8, 9, 10, 11, 12, 13, 14.
In Cancer	7, 8, 9, 10, 11, 12, 13.
In Leo	20, 21, 22, 23, 24, 25.
In Virgo	14, 15, 16, 17, 18.
In Libra	12, 13, 14, 15, 16, 17, 18, 19.
In Scorpio	7, 8, 9, 10, 11, 12, 13, 14.
In Sagittarius	1, 2, 3, 4, 5, 6, 7, 8.
In Capricornus	13, 14, 15, 16, 17, 18, 19.
In Aquarius	21, 22, 23, 24, 25.
In Pisces	9, 10, 11, 12, 13, 14.

He has for his Face, or Decanate:

Of Gemini	1, 2, 3, 4, 5, 6, 7, 8, 9, 10.
Of Leo	11, 12, 13, 14, 15, 16, 17, 18, 19, 20.
Of Libra	21, 22, 23, 24, 25, 26, 27, 28, 29, 30.
Of Capricornus	1, 2, 3, 4, 5, 6, 7, 8, 9, 10.
Of Pisces	11, 12, 13, 14, 15, 16, 17, 18, 19, 20.

Zaid n. adwan

Mars has Aries for his day-house and Scorpio for his night-house. He is exalted in Capricornus, and has his fall in Cancer.

He governs the watery Triplicity, viz., Cancer, Scorpio and Pisces, and he has these degrees in each sign for his Terms:

In Aries	22, 23, 24, 25, 26.
In Taurus	27, 28, 29, 30.
In Gemini	26, 27, 28, 29, 30.
In Cancer	1, 2, 3, 4, 5, 6.
In Leo	26, 27, 28, 29, 30.
In Virgo	25, 26, 27, 28, 29, 30.
In Scorpio	1, 2, 3, 4, 5, 6.
In Aquarius	26, 27, 28, 29, 30.
In Pisces	21, 22, 23, 24, 25, 26.

He has allotted to him for his Face these degrees:

In Aries	1, 2, 3, 4, 5, 6, 7, 8, 9, 10.
In Gemini	11, 12, 13, 14, 15, 16, 17, 18, 19, 20.
In Leo	21, 22, 23, 24, 25, 26, 27, 28, 29, 30.
In Virgo	1, 2, 3, 4, 5, 6, 7, 8, 9, 10.
In Pisces	21, 22, 23, 24, 25, 26, 27, 28, 29, 30.

The Sun rules the fiery Triplicity—Aries, Leo and Sagittarius—by day. He is exalted in the sign of Aries, and receives his fall in Libra.

He has no degrees admitted him for his Terms, but in the twelve signs he has the following degrees for his Face:

zain.adwan

In Aries	11, 12, 13, 14, 15, 16, 17, 18, 19, 20.
In Gemini	21, 22, 23, 24, 25, 26, 27, 28, 29, 30.
In Virgo	1, 2, 3, 4, 5, 6, 7, 8, 9, 10.
In Scorpio	11, 12, 13, 14, 15, 16, 17, 18, 19, 20.
In Capricornus	21, 22, 23, 24, 25, 26, 27, 28, 29, 30.

Venus governs the earthy Triplicity—Taurus, Virgo and Capricornus—by day. She is exalted in Pisces, and has her fall in Virgo. She has the following degrees for her Terms:

In Aries	7, 8, 9, 10, 11, 12, 13, 14.
In Taurus	1, 2, 3, 4, 5, 6, 7, 8.
In Gemini	15, 16, 17, 18, 19. 20.
In Cancer	21, 22, 23, 24, 25, 26, 27.
In Leo	14, 15, 16, 17, 18, 19.
In Virgo	8, 9, 10, 11, 12, 13.
In Libra	7, 8, 9, 10, 11.
In Scorpio	15, 16, 17, 18, 19, 20, 21.
In Sagittarius	9, 10, 11, 12, 13, 14.
In Capricornus	1, 2, 3, 4, 5, 6.
In Aquarius	13, 14, 15, 16, 17, 18, 19, 20.
In Pisces	1, 2, 3, 4, 5, 6, 7, 8.

The following degrees are allowed for her Face:

In Aries	21, 22, 23, 24, 25, 26, 27, 28, 29, 30.
In Cancer	1, 2, 3, 4, 5, 6, 7, 8, 9, 10.
In Virgo	11, 12, 13, 14, 15, 16, 17, 18, 19, 20.

Zaid H. adwan

In Scorpio	21, 22, 23, 24, 25, 26, 27, 28, 29, 30.
In Pisces	1, 2, 3, 4, 5, 6, 7, 8, 9, 10.

Mercury governs the airy Triplicity, viz., Gemini, Libra and Aquarius, by night. He has his exaltation in Virgo, and his fall in Pisces. He has the following degrees for his Terms:

In Aries	15, 16, 17, 18, 19, 20, 21.
In Taurus	9, 10, 11, 12, 13, 14, 15.
In Gemini	1, 2, 3, 4, 5, 6, 7.
In Cancer	14, 15, 16, 17, 18, 19, 20.
In Leo	7, 8, 9, 10, 11, 12, 13.
In Virgo	1, 2, 3, 4, 5, 6, 7.
In Libra	20, 21, 22, 23, 24.
In Scorpio	22, 23, 24, 25, 26, 27.
In Sagittarius	15, 16, 17, 18, 19, 20.
In Capricornus	7, 8, 9, 10, 11, 12.
In Pisces	15, 16, 17, 18, 19, 20.

These degrees are assigned him for his Face:

In Taurus	1, 2, 3, 4, 5, 6, 7, 8, 9, 10.
In Cancer	11, 12, 13, 14, 15, 16, 17, 18, 19, 20.
In Virgo	21, 22, 23, 24, 25, 26, 27, 28, 29, 30.
In Sagittarius	1, 2, 3, 4, 5, 6, 7, 8, 9, 10.
In Aquarius	11, 12, 13, 14, 15, 16, 17, 18, 19, 20.

The Moon governs the earthy Triplicity, viz., Taurus, Virgo and Capricornus, by night.

zaid.n.adwan

She is exalted in Taurus, and has her fall in Scorpio. The Sun and the Moon have no terms assigned them.

In the twelve signs she has these degrees assigned her for her Face:

In Taurus	11, 12, 13, 14, 15, 16, 17, 18, 19, 20.
In Cancer	21, 22, 23, 24, 25, 26, 27, 28, 29, 30.
In Libra	1, 2, 3, 4, 5, 6, 7, 8, 9, 10.
In Sagittarius	11, 12, 13, 14, 15, 16, 17, 18, 19, 20.
In Aquarius	21, 22, 23, 24, 25, 26, 27, 28, 29, 30.

A planet in his fall is very weak in his influence. The Houses count first in dignity, then the Exaltation; afterwards the Triplicity, the Terms, and the Faces.

The meaning of this is, if a planet is in any of the signs we call his house or houses, he is essentially strong, and he is allowed five dignities.

If he is in the sign in which he is said to be exalted, he is allowed four dignities.

If he should be placed in any of the signs allowed him for his Triplicity, he is allowed three dignities.

If in any of the degrees in the signs which are given as his Terms, he has two dignities.

If in any of the degrees of the sign given to him as his Face, he is allowed one essential dignity. Accidental dignities are when a planet is swift in motion, angular or in sextile aspect with Jupiter or Venus.

There was a great difference between the Arabian, Indian, and Greek methods in the disposing of the degrees of the sign to each planet until the time of Ptolemy. Since then almost all astrologers followed the method he left, which is that which has been given in this chapter.

Zaid n. adwan

CHAPTER V.

OF THE INFLUENCES OF THE SEVEN PLANETS

The planet Saturn is the most remote of the seven planetary orbs recognised by the ancient writers on astrology. He is of a pale ash colour, slow in motion, only finishing his course through the twelve signs of the zodiac in 29 years and about 157 days. His greatest north latitude from the ecliptic is 2 degrees 48 minutes; his south latitude is 2 degrees 49 minutes.

Those born with this planet well-dignified [4] are studious, grave, economical, prudent, patient and in all their actions sober and somewhat austere. They are not much given to the love of women, but they are persons of much depth of feeling, and, when they do love, they are very constant. They are given to the study of occult matters, [5] and are of a melancholic, suspicious and jealous temperament. In person *when well-dignified* Saturn gives a rather tall stature and long limbs. The hair is dark, the eyebrows much marked and generally meeting between the eyes, which are dark brown, deep set and close together. The nose is long and generally somewhat bent over the lips and the under jaw slightly protrudes. The complexion is sallow, the ears large and the hands and feet are generally long, but not fleshy.

Those born under the potent aspect of Saturn are generally slow of speech and their voices are harsh; when Saturn rises in a horoscope *devoid of dignities*, the native is envious, covetous, malicious, subtle, untruthful and of a discontented disposition. In person frequently deformed, with long and irregular features, the eyes and hair dark and the skin yellow and harsh.

In man's body this planet rules the spleen, the right ear, the lips and the teeth. In illness he gives ague, palsy, ruptures (especially should he rule in the sign of Scorpio),

zain.adwan

jaundice, toothache and all affections of the sight, of the ear, of the teeth and jaws and of the legs.

The herbs he governs are the hemlock, hellebore, burdock, sage, henbane, rue, nightshade and mandrake.

The trees under his rule are the willow, the yew, the cypress, the box-tree and the pine.

The beasts he governs are the elephant, the wolf, the bear, the dog,[6] the basilisk, the crocodile, the scorpion, the serpent, the rat, the mouse and all manner of creeping things; among birds, the crow, the cuckoo, the raven, the owl and the bat.

Of fish he rules the eel, the tortoise and all shell fish.

The minerals he governs are lead and the dross of all metals.

His stones are jet, onyx and all dark stones which are incapable of polish. The colour he rules is black.

He rules Saturday—the first hour after sunrise, and the eighth hour of the same day. His number is 55. In gathering the herbs under his rule the ancients were particular to do so in his hours, as this rendered the medicament more powerful. This is to be observed regarding the herbs ruled by all the planets.

Saturn's orb is nine degrees before and after any aspect; that is, his influence begins to operate when either he applies to any planet or it applies to him within nine degrees of his perfect aspect, and his influence continues in force until he is separated nine degrees from the aspect. His angel is Cassiel. His friends are Jupiter, Venus, Mercury and the Moon; his enemies are Mars and the Sun.

Jupiter is the next planet below Saturn and is of a bright, clear, azure colour. He much exceeds Saturn in motion, as he finishes his course through the twelve signs in twelve years. His greatest north latitude is 1 degree 38 minutes, and his greatest south latitude

1 degree 40 minutes. When he rises at birth well-dignified he gives an erect, tall stature, sanguine complexion, oval face, large grey eyes, thick brown hair, full lips and good teeth. In temperament those born under the good influence of this planet are honourable, generous and hospitable, but loving material pleasures, kind and affectionate to wife and family, charitable, desiring to be well thought of and hating all mean and sordid actions. The voices of those born under Jupiter are clear and sonorous. When this planet rises *devoid of dignities* the native will be gluttonous, profligate, vain, and boastful, of mean abilities and shallow understanding, easily seduced to extravagance and a tyrant to those of his family and household.

In man's body he rules the lungs and the blood, and of diseases he gives apoplexy, gout, inflammation of the lungs, pleurisy and all illnesses proceeding from corruption of the blood.

The herbs he governs are cloves, mace, nutmeg, gilliflower, marjoram, mint, borage and saffron.

Of trees, he rules the mulberry, the olive, the vine, the fig, the beech and the pear-tree.

Of beasts, the sheep, the hart, the ox and all those animals that are useful to man.

Of birds, the stork, the snipe, the lark, the eagle, the pheasant, the partridge and the peacock.

Of fishes, the whale, the dolphin and the sword-fish.

His metal is tin.

His stones are the sapphire, the amethyst and the emerald.

Of colours he rules red mixed with green.

His day is Thursday and he rules the first hour after sunrise and the eighth hour. His number is 78.

zain n. adwan

His orb is 9 degrees before and after any aspect.

All the planets except Mars are his friends.

His angel is Zadkiel.

Mars in order succeeds Jupiter. He appears of a red colour, and finishes his course through the zodiac in 1 year 321 days. His greatest north latitude is 4 degrees 31 minutes. His south latitude is 6 degrees 47 minutes. When he is well-dignified in a horoscope, the native is courageous, confident, loving war and all that belongs to it, jealous of honour, hot-tempered and a great lover of field-sports. In person he will be of middle stature, broad-shouldered and with big bones; the complexion of a red fairness; the hair is crisp or curly and also red, but this varies slightly according to the sign rising at birth; in watery signs the hair is not so red, and in earthy signs it is more chestnut; the eyes are grey and have a bold, fixed glance like that of a hawk.

When he is ill-dignified at birth, the native is turbulent, cruel, boastful, a promoter of sedition, ungracious in manners and unscrupulous in his actions, with no fear of either God or man. He rules the head and face, the gall, the throat and intestines; and the diseases he gives are fevers, carbuncles, smallpox, all throat affections, all hurts to the head and face (especially by iron), and all diseases which arise from too much heat of blood; also accidents from four-footed beasts.

The herbs over which he rules are the nettle, the thistle, onions, scammony, garlic, horehound, cardamons, mustard and all herbs giving heat.

Of trees, all those which are of a prickly nature, such as the holly, the thorn and the chestnut.

Of beasts, all fierce animals—the tiger, the panther, the wolf, the horse, the leopard, the wild ass and the bear.

Zaid n. adwan

The dog is sometimes assigned to Mars on account of its courage and combativeness. This delightful animal is probably ruled by both Saturn and Mars; the former giving it the quality of fidelity which it possesses in a degree beyond all other creatures.

Of fish, the pike, the barbel and the sword-fish.

Of birds, the hawk, the vulture, the kite, the eagle, the magpie and the cock, all of which are combative.

The metal he rules is iron. The colour he rules is red.

The stones, the carbuncle, the ruby and the blood-stone.

His orb is 7 degrees before and after any aspect.

He governs Tuesday—the first hour after sunrise, and the eighth. His number is 39.

His friend among the planets is Venus, all the others are his enemies.

His angel is Samael.

The Sun passes through all the twelve signs of the zodiac in one year and a few hours over the 365 days which constitute the year. He has no latitude.

When the Sun rises at a birth well-dignified, the native is of an honourable disposition, but always desiring to rule, loving pomp, yet affable, speaking with gravity and without too many words and possessing much self-reliance and dignity of manner. In person he will be tall, well made, with golden hair, yellowish skin, large and piercing eyes and long, straight and well-formed features.

When ill-aspected the native is arrogant, boastful, a spendthrift, proud, yet in poverty hanging on other men's charity, very loquacious, restless and without judgment.

Zaid n. adwan

He governs the heart, the brain, the right eye and the arms; and the diseases he causes are all illnesses of the heart, such as swoons, palpitations, cramps, also diseases of the mouth, the brain, and the eyes.

Of colours he rules the yellow and orange colour.

The plants subject to the Sun are all those of pungent odours, such as the marigold, heliotrope, rosemary, balsam, peony, spikenard, musk, St. John's wort, and ginger.

Of trees he rules the palm, the laurel, the cedar, the orange-tree and the citron-tree.

Of beasts, the lion, the ram, the goat.

Of birds, the eagle, the cock, the buzzard.

Of fish, the star-fish, the crab-fish and the sea-fox.

He governs Sunday. His number is 34.

Of metals, gold.

Of colours he rules the yellow.

Of stones, the topaz, amber, chrysolite and all yellow stones.

His orb is 15 degrees before any aspect, and as many after separation.

His friends are all the planets except Saturn and Mars.

His angel is Michael.

After the Sun the planet Venus succeeds in order; she is of a bright shining colour. Her greatest north or south latitude is 2 degrees and 2 minutes. When she rises well-dignified in a nativity the person born will be of middle stature, rather inclining to shortness, with a beautiful complexion, light brown hair, the eyes large, of a blue or grey colour and with a slow and rather languishing movement, red lips, and dimples in the cheeks, chin

Zain n. adwan

and about the mouth. In disposition, gracious, very tender, inclined to love-making; easy of belief and not given to labour about anything; fond of music, plays, and all sorts of merry-makings.

When ill-dignified at birth Venus causes the native to be over-fat, with thick lips, and much flesh about the chin and cheeks. In disposition, sensual, riotous and immoral.

Venus governs the lower parts of the body, and the illnesses she gives are cancer and all affections of the womb.

All the herbs she governs have a sweet smell and, generally, have smooth leaves and white flowers, such as the lily, both white and yellow, and the lily of the valley, also the water lily, the myrtle, maidenhair, violets and roses.

The trees she rules are the walnut, the almond, the apple-tree, the box-tree, the sycamore, the ash and myrtle.

Of beasts, the hart, the rabbit, the calf and all small cattle.

Of birds, the dove, the sparrow, the nightingale, the swan, the pelican and the swallow.

Her metal is copper.

Her stones, white and red coral, rubies, the beryl, turquoise and lapis lazuli, because it expels melancholy.

Her colours are white and purple.

Her orb is 7 degrees before and after any aspect.

Her day of the week is Friday, of which she rules the first and eighth hour after sunrise. Her number is 45.

Her friends are all the planets, but Saturn is the least sympathetic to her.

zain n. adwan

Her angel is Anael.

Mercury is of a soft silver colour. His greatest north latitude is 3 degrees 33 minutes. His greatest south latitude is 3 degrees 33 minutes.

When he rises well-dignified at a birth the native is a person of subtle intellect, an excellent logician, and possessing much eloquence in his speech; sharp and witty, of admirable memory, curious in occult knowledge, given to divination, and, if he should turn his attention to trade, no man would exceed him in the invention of new ways to gain wealth.

In person, when Mercury rises well-dignified, the native is of rather small stature, but elegantly formed, very active and supple in his limbs, and with long arms; he will have a long, narrow face, a high forehead, rather swelling at the temples, grey eyes with brown spots in them, delicate mouth, straight eyebrows, a skin of a pale yellow or olive colour, the hair of a red-brown, commonly called auburn.

When ill-dignified at birth Mercury gives a person of very small stature, with small, insignificant features and very small and quickly-moving eyes; and in character he is shifty, a boaster, foolishly loquacious and a great liar.

He rules the liver, the tongue and the nerves, and the illnesses he gives are epilepsy, giddiness, dry cough, any affection of the tongue, and all nervous affections.

The herbs attributed to him are generally those having a subtle smell, and having effect on the tongue, brain, lungs, or memory; they are vervain, adder's-tongue, aniseed, dragon-wort, and the reed.

The trees are the elder and the filbert-tree.

The animals are the squirrel, the weasel, the spider, the greyhound, the fox, the ape and all cunning and quickly-moving creatures.

zain n. adwan

The birds, the parrot, the magpie, the crane, the linnet and the swallow.

Of fish, the jack-fish and the mullet.

His metal is quicksilver.

His stones all those of divers colours, white and red carnelian and marcasite, or fire-stone.

In colours he rules azure, and all light blue colours.

His orb is 7 degrees before and after any aspect.

He governs Wednesday—the first hour and the eighth after sunrise. His number is 114. The Moon, Venus, Jupiter, the Sun and Saturn are his friends; Mars is his enemy.

His angel is Raphael.

The Moon is the nearest to the earth of all the seven planets. She finishes her course through the whole twelve signs in 27 days 7 hours and 36 seconds. Her greatest north latitude is 5 degrees and about 17 minutes, her greatest south latitude 5 degrees and 12 minutes.

When she rises well-placed in a horoscope, she signifies a person of soft and gentle manners, timid, imaginative, loving pleasure and ease, yet fond of moving from place to place, rather capricious, but of a poetic and romantic turn of mind. In person, those born under good aspects of the Moon are of middle height, with a round head and face, pale, soft skin, large light eyes, usually one a little larger than the other. The whole body inclined to be fleshy, the lips full, and the hair of a dull, light colour, but not at all inclined to gold.

When the Moon is ill-aspected at birth the native is indolent, sometimes a drunkard and vagabond, generally a liar, and, as Lilly puts it, "a muddling creature."

Zaid H. adwan

The Moon governs the left side and the bladder. She gives dropsy, all cold and rheumatic diseases, colds or hurts in the eyes, convulsive fits, hysteria, and feminine weaknesses.

The plants she governs are all those which have soft, juicy leaves, such as the lettuce, the melon, the gourd, the poppy, mushroom, cabbage and colewort. Of trees, all those which have round, spreading leaves, such as the lime-tree and the sycamore.

The beasts she rules are those which love the water, as the otter and the seal.

She rules all sea fowl and also the goose, the duck and the night owl.

Of fish, the oyster, the cockle and the lobster.

Her colours are light greenish-blue mixed with white.

Her metal is silver.

Her stones, pearls, diamonds, opals, crystals and selenite.

Her orb is 12 degrees before and after any aspect.

Her day is Monday; the first hour and the eighth after sunrise are hers. Her number is 45.

Her friends are Venus, Jupiter, the Sun, Saturn and Mercury.

Her enemy among the planets is Mars.

Her angel is Gabriel.

zaid n. adwan

To face Chapter VI.

CHAPTER VI.

CONCERNING THE TWELVE HOUSES OF HEAVEN AND THEIR POWERS

The ancient astrologers divided the heavens into twelve houses.

The First House.—This is called the *Ascendant,* and the planet rising therein—whether well or ill-dignified—will materially affect the mind, bodily appearance and fate of the native through his whole existence. This house is masculine, and governs the head and face of man and, if the planet Mars be in this house at the time of birth, there will always be some blemish or mole in the face of the native; if a few out of the degrees have ascended the scar or blemish is, without fail, on the upper part of the head; if the middle part of the sign ascends the mark is in the middle of the face; if the latter part of the sign

is ascending the mark is near the chin. This house represents the head, the tongue and the memory, and it governs in colours white.

The Second House.—This house has signification of the native's wealth and worldly goods. The house is feminine, ruling the neck, and the colour is green.

The Third House.—This governs brothers and sisters, short journeys, neighbours, letters and writings. It is masculine and governs the hands, arms and shoulders; its colours are red and yellow mixed.

The Fourth House.—This rules the father, inheritances or property of the native, and shows his condition at the close of life. It is feminine, and rules the stomach, breast and lungs; its colour is red.

The Fifth House.—This signifies the children of the native, also his success in speculation and hazardous games, the pleasures he enjoys and the wealth of the father. It rules the heart, back and liver, is masculine, and represents in colour black and white mixed.

The Sixth House.—This concerns the native's servants, sheep, goats and small cattle. It also signifies the father's kindred. This house is feminine. It rules the belly and intestines and its colour is black.

The Seventh House gives judgment of marriage and describes the man or woman in all love questions. It is masculine, it rules the haunches, and its colour is black.

The Eighth House argues of death, of legacies and wills, also of the kind of death a man shall die; it is a feminine house. It rules the lower parts of the trunk of the body; its colours are green and black.

zain. adwan

The Ninth House gives judgment on voyages and long journeys, and also on events happening to the wife's kindred. It rules the hips and thighs. It is a masculine house; its colours are green and white.

The Tenth House is called the *Mid-heaven,* and is feminine. This concerns the native's mother, and also his calling. It rules the knees and hams, and its colours are red and white.

The Eleventh House represents friends and friendship. It is masculine and rules the legs.

The Twelfth House.—This house is often called the *Evil Dæmon,* for it is the house of sorrow, self-undoing, enemies and imprisonment. It governs great cattle. It is feminine, and rules the feet and toes, and in colour it governs green.

The strongest houses are the first (the *Ascendant*) and the tenth (the *Mid-heaven*). The first, fourth, seventh, and tenth are called Angular Houses, and represent the four cardinal points of the compass; thus the first is east, the seventh west, the fourth is north, and the tenth south. The second, fifth, eighth, and eleventh houses are called Succedent Houses; the third, sixth, ninth, and twelfth houses are termed Cadent Houses (see plate 1). Any planet posited in a Cadent House is regarded as weak in its effects on the native. It is necessary to have thoroughly mastered the influences of the twelve houses, as well as those of the seven planets, and of the signs of the zodiac, before attempting to cast a nativity or to work a horary question.

CHAPTER VII.

AN EXPLANATION OF VARIOUS TERMS USED IN ASTROLOGY

Ascension, Right.—The distance any body or point in the heavens is from the beginning of the ecliptic or first point of Aries. It is measured in degrees and minutes of a degree. It is thus abbreviated, A. R.

Ascension, Oblique.—If a star be not on the equator, it will, when it rises, form an angle with that part of the equator which is rising at the same time, and this is called its

Ascensional Difference.—This, added to its right ascension (A. R.) if it have *south* declination, but subtracted from it if it have *north* declination, gives its oblique ascension.

Application signifies the approach of two planets and is of three kinds: first, when a planet, swift of motion, applies to one of slower progress: for example, we will suppose Mercury posited in 16 degrees of the sign Gemini, and Mars in 21 degrees of the same sign (*both being in direct motion*), Mercury being swifter would overtake and form a conjunction with Mars, which is termed a *direct application*. The second kind of application is formed by two retrograde planets: thus we will suppose Mercury in 16 degrees of Gemini and Saturn in 15 degrees of the same sign, both retrograde. Mercury being the swiftest planet, applies to Saturn, a more ponderous planet, by retrogradation, and this is called a *retrograde application*. The third kind of application is when one planet, being direct in motion, meets another which is retrograde: for instance, we will suppose Mercury retrograde in 16 degrees of Gemini, and Saturn *direct* in motion in 12 degrees of the same sign; here Mercury, being the higher planet, *applies to a conjunction* of Saturn by a retrograde motion. These two last are considered *evil* applications. It should also be remembered that the superior planets, Saturn, Jupiter and Mars, never apply to the inferior planets, Venus, Mercury and the Moon, except by retrograde motion; but the inferior planets apply in both ways.

Besieging signifies a planet situated between the two malevolent planets, Saturn and Mars: thus, if Saturn were in the 12th degree of Aries, Jupiter in the 14th, and Mars in

the 16th, Jupiter would then be *besieged* by the two malefic planets, Saturn and Mars. This is, of course, an evil position.

Cazimi.—A planet is said to be in *cazimi* when it is in the heart of the Sun: that is, only 17 minutes before or after the Sun. All astrologers agree that a planet is fortified by this position, but a planet when *combust* is very evil in its influences.

Direct motion signifies that a planet is moving on its natural course, according to the succession of the signs of the zodiac: thus a planet is *direct in motion* when it moves from Aries to Taurus, or from Taurus to Gemini.

Frustration means the approach of a swift planet to an aspect with one of slower motion; but before it can approach near enough to join that aspect the more weighty planet is joined to some other, by which the first aspect is frustrated.

Hayz is when a masculine diurnal planet is situated above the horizon in the daytime, or when a feminine nocturnal planet is placed below the horizon in the night-time; this is fortunate in its influence.

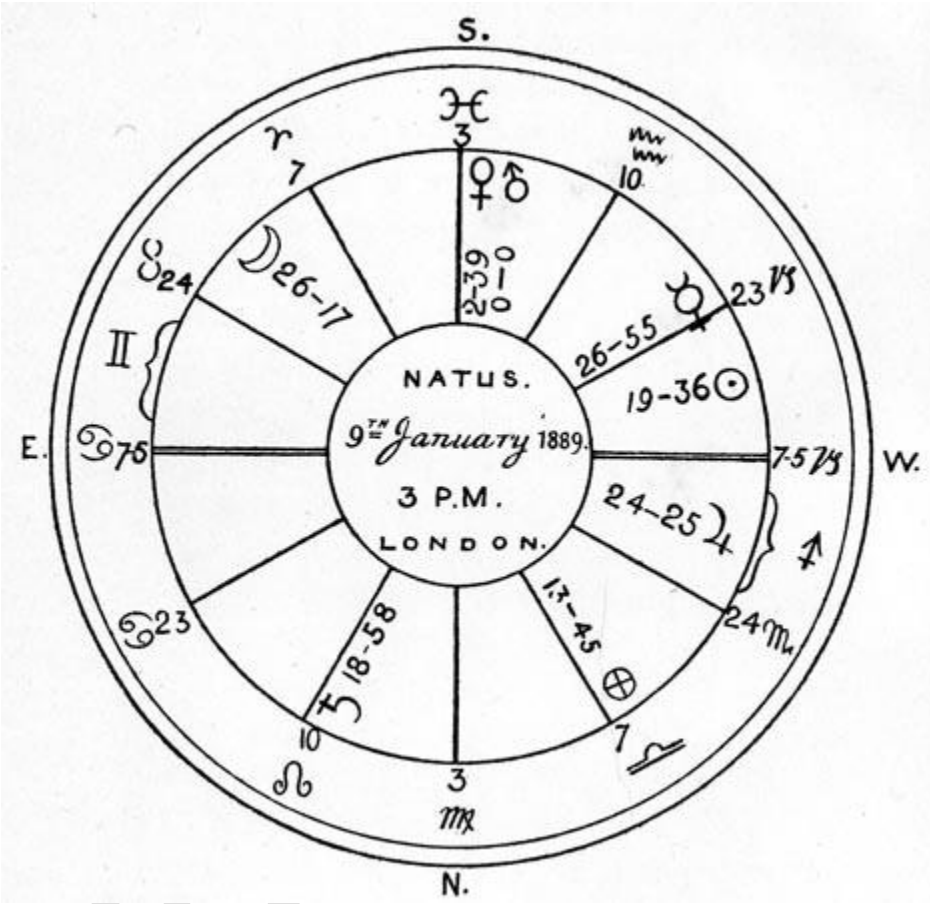
Node.—That part of the ecliptic where a planet passes out of north into south latitude is its south node; that where it goes into north latitude is its north node.

Oriental and Occidental.—A planet, when oriental, rises before the Sun; when occidental sets after him and is seen above the horizon when the Sun is down; consequently, when a planet is oriental it is posited in the east, and when occidental, in the west.

From the fourth house eastward to the tenth is oriental and from the tenth westward to the fourth is occidental. But ☉ or ☽ are *oriental* between the first and tenth and its opposite quarter and are *occidental* between the tenth and seventh and its opposite quarter.

zain. adwan

Void of course is when a planet is separated from another planet, and does not, during its continuance in the same sign, form any aspect with any other planet. This most usually happens with the Moon. The effect of this is



To face Chapter VIII.

CHAPTER VIII.

OF THE FIGURE OF THE HEAVENS

This was formerly termed a *horoscope*, but is now more generally called a *figure of the heavens*. It is simply a scheme, or plan, representing an accurate picture of the heavens—that is, of the positions of the Sun, Moon, and planets, and, in some instances,

of the fixed stars also, for the moment at which a child is born. In horary questions the figure is drawn for the required time, which may be the moment of the propounding of a question to an astrologer, or of the occurrence of any event of the result of which astrological information is desired.

This map, which contains the twelve divisions already described as the twelve houses of heaven, may be drawn in either a square or circular form. Lilly and other mediæval writers use both forms indiscriminately; but as the latter is more easily understood, the diagram (plate 2) is drawn up in that manner. It will be seen that it is formed of three circles. In the centre space the date, time and place of the event of a horary question are entered, and in a nativity the name, sex and moment of birth of the native. The next space (divided into twelve equal parts for the houses) is reserved for the planets and in the outer space are placed the signs of the zodiac, with the number of their degrees, on the cusp of each house. The cusps of the Houses are represented by that line between each house. Having obtained an Ephemeris, or astrological almanack [7] for the year required, we must find the Sidereal Time for the day and month of the birth, or question; then, if the time of the event be *before* noon we must *deduct* the difference between the given time and noon from the Sidereal Time of the day; for example, on the day of the event (the 9th January, 1889), the Sidereal Time at noon is shown by the Ephemeris to be 19 hours 16 minutes 51 seconds, if the birth had been at 9 a.m. The difference between 9 a.m. and noon is 3 hours. We should, therefore, have to *deduct* 3 hours from 19 hours 16 minutes 51 seconds, which gives 16 hours 16 minutes 51 seconds, the Sidereal Time required.

As the event is supposed to happen at 3 in the *afternoon*, we must *add* the difference between noon and the time given to the Sidereal Time of the day. The difference between noon and 3 p.m. is 3 hours, and, as the Sidereal Time on the 9th January, 1889, is 19 hours 16 minutes 51 seconds, we *add* 3 hours to this amount, which gives 22 hours 16 minutes 51 seconds, the Sidereal Time required.

We must now proceed to place the signs for 3 p.m. on the 9th January, 1889, which is thus done: We turn to the "Table of Houses" (which will be found at the end of the Ephemeris), and having found (under the column headed "Sidereal Time") the nearest time to 22 hours 16 minutes 51 seconds, which in this case is 22 hours 16 minutes 48 seconds for the latitude of London, we see in the next column (headed 10) the sign ♓ (Pisces), and the number 3° opposite our Sidereal Time, showing that the third degree of Pisces is on the cusp of the 10th house, In the next column (headed 11) we see ♈, and the number 7°; we therefore place 7° ♈ on the cusp of the 11th house, next 24° ♉ on the 12th; then 7° 5′ ♋ on the Ascendant (or first house), 23° ♋ on the 2nd and 10° ♌ on the 3rd; for the remaining houses we place the signs *in order* opposite to those already given, keeping the same number of degrees to each corresponding house and sign. The opposite house to the 10th is the 4th, and the opposite sign to ♓ is ♍; we therefore place 3° ♍ on the cusp of the 4th house, and so on of the rest. It will, however, now be seen that the two signs ♊ and ♐ are missing; these signs are "intercepted," which means that they lie between two houses without occupying the cusp of either; they must, therefore, be placed in their order *between* the cusps of the houses. This is, of course, not always the case, and some horoscopes will have no intercepted signs.

HOW TO PLACE THE PLANETS.

In the Ephemeris the longitudes of the planets are given daily for mean noon; so, to find the *exact* place of a planet for a given time, we must note the difference of longitude between the previous noon and noon of the day for drawing the map for a.m. and for p.m., the difference between noon of the day and noon of the day after. This *difference* is the motion of the planet in 24 hours, which we must work thus: As

24 hours are to—hours (*i.e.*, the difference between the given time and noon), so is the daily motion to the motion required. For example, the ☉ at noon on the 6th January is (omitting seconds) in 19° 29′ ♑, and on the 10th January at noon he is in 20° 30′ ♑ , which gives a daily motion of 59 minutes. We must find his place for 3 p.m. on the 9th January. As 24 hours are to 3 hours, so are 59 minutes to the time required; this equals about 7 minutes, which we add to the ☉'s longitude at noon on the 9th. If the event had been for a.m. this amount would have been *deducted* from the ☉'s longitude at noon on the day of the event. We must proceed in the same way for the other planets and place them in the map according to their positions in respect to the degrees on the cusps of the houses. The ☉ will be in 19° 36′ ♑, or about the middle of the 7th house. And note that the number of degrees of a sign on the cusp of any house shows that that sign commenced *in* the previous house. Supposing the ☉ had been 1° of ♑, we should then have placed it in the 6th house, a little below the cusp of the 7th. When a planet is *Retrograde* (shown in the Ephemeris thus, *R.*), we *add* the amount to the longitude when the event is before noon or a.m., and *deduct* it from the longitude when the event is after noon or p.m. The mode of giving the judgment on a horoscope will be shown farther on.

CHAPTER IX.

OF THE INFLUENCES OF THE FIXED STARS

The fixed stars are so called because they appear to keep at the same distance from one another in the heavens. All of these stars have their respective influences analogous to those of the planets. The following table of the principal fixed stars, with their several magnitudes and natures, will be found useful. It is only those of the first and second

magnitude which much affect us; the influence of those stars marked as of fourth magnitude is very slight. The time of the rising and setting of the fixed stars varies according to the latitudes of the places of observation. Their longitudes increase at the annual rate of 50 seconds, but their latitudes vary very little. The right ascension and declinations of the numerous fixed stars are given every year in the Nautical Almanack.

TABLE OF THE PRINCIPAL FIXED STARS, WITH THEIR MAGNITUDES AND NATURES.

Stars.	*Magnitudes.*	*Natures.*
South End of the Tail of the Whale	2	Of the nature of Saturn.
The Star in the Wing of Pegasus	2	Mars and Mercury.
The Head of Andromeda	2	Jupiter and Venus.
The Whale's Belly	4	Saturn.
The Girdle of Andromeda	2	Venus.
The Bright Star in the Head of Aries	3	Saturn and Mars.
The Left Foot of Andromeda	2	Venus.
The Bright Star in the Jaw of the Whale	2	Saturn.
Caput Algol	2	Saturn and Jupiter.
The Pleiades or Seven Stars	5	Mars and the Moon.
The Middle Star in the Pleiades	3	Mars and the Moon.
Oculus Taurus	3	Venus.
Aldebaran	1	Mars.
Rigel	1	Jupiter and Venus.
The Foremost Shoulder of Orion	2	Mars and Mercury.
The She-Goat	1	Mercury and Mars.
The Middle Star in Orion's Belt	2	Jupiter and Saturn.

zain n. adwan

The Highest Star in the Head of Orion	4	Jupiter and Saturn.
The Star in the Horn of the Bull	3	Mars.
Propus	4	Mars.
The Right Shoulder of Auriga	2	Mars and Mercury.
The Foot of Gemini	2	Mercury and Venus.
Castor	2	Mars, Venus and Saturn.
Pollux	2	Mars.
The Smaller Dog Star	2	Mercury and Mars.
Præsepe [8]	1	Mars and the Moon.
North Asellus	4	Mars and the Sun.
South Asellus	4	Mars and the Sun.
Cor Leonis or Regulus	1	Mars.
Heart of Hydra	1	Saturn and Venus.
Vindemiatrix	3	Saturn, Venus and Mercury.
The Back of the Lion	2	Saturn and Venus.
The Tail of the Lion	1	Saturn, Venus and Mercury.
Crater	4	Venus and Mercury.
Arcturus	1	Jupiter and Mars.
The Virgin's Spike or Arista	1	Venus and Mars.
The South Balance	2	Saturn and Venus.
The North Balance	2	Jupiter and Mars.
The Left Hand of Ophiucus	3	Mars and Saturn.
The Highest Star in Head of Scorpio	2	Saturn and Venus.
The Left Knee of Ophiucus	3	Saturn and Venus.

zaid n. adwan

Cor Scorpio	2	Mars and Jupiter.
Antares	1	Mars.
The Right Knee of Ophiucus	3	Saturn and Venus.
The Bright Star of the Vulture	2	Saturn and Mercury.
The Mouth of Pegasus	3	Venus and Mercury.
The Tail of the Goat	3	Saturn.
Marchab	2	Mars and Mercury.
Fomalhaut	1	Venus and Mercury.
Scheat-Pegasi	2	Saturn.

To know when any of these fixed stars will affect the horoscope we must note the sign and degree on the cusps of the houses, and if (on consulting the Ephemeris) any of these stars should be found to be ascending or descending within five degrees of the signs upon the cusps of the several houses, they must be entered in the same manner as the planets, and their qualities weighed according to the nature of the planet or planets with which they correspond, as shown by the table given.

The influences of the fixed stars are not much considered by the modern astrologers, yet in certain positions their power is undeniable. The conjunction and opposition are the only aspects to be considered in regard to them, as they do not operate on the planets by sextile, square, or trine aspects. When a fixed star happens to be in conjunction with the Sun at birth, certain effects are distinctly traceable. For example, the Sun conjoined with Aldebaran, Hercules, Antares, or any fixed star having the nature of Mars, threatens a violent death, or, at best, constant illness to the native. The Sun, with the Pleiades, Castor, Pollux, or Præsepe, shows a cruel and headstrong disposition in the native and the *probability* of violent death. The star Arista, with the Sun, gives great and lasting good fortune. All the stars of the nature of Saturn, conjoined with the Sun, bring calamity and disgrace. When a fixed star, whose latitude does not differ much

from that of the Moon, is in conjunction with her, certain effects are produced; for instance, when she is conjoined with Aldebaran or Pollux violent death is indicated; when with the Pleiades injury to the eyes or blindness. The Moon with Antares and in opposition to Saturn with Aldebaran, shows death by strangulation. The Moon, with Aldebaran or Antares either in the ascendant or in the mid-heaven, gives brilliant honours, but not without many attendant dangers and hair-breadth escapes. Fixed stars of the *first* magnitude, near the cusp of the seventh house, show a rich wife, but her disposition will sympathise with the planetary qualities of the star. Fomalhaut and Rigel, in either the ascendant or mid-heaven, give fame after death. Sirius, the Dog Star, in conjunction with the Sun, either in the ascendant or mid-heaven, gives preferment and honours from royalty. Caput Algol, in conjunction with the Sun in the eighth house and in square to Mars, shows decapitation.

CHAPTER X.

OF THE EFFECT OF EACH PLANET IN EACH OF THE TWELVE HOUSES

Saturn in the first house, or ascendant, shows melancholy and many sorrows, and if near the ascendant probability of early death; in the second house pecuniary troubles; in the third quarrels with brothers and sisters, and dangers and losses in travelling; in the fourth house death of father or mother, and loss of friends; in the fifth barrenness or death of children; in the sixth illness, worries with servants and losses from cattle; in the seventh an ungovernable wife and unhappy marriage; in the eighth violent death and loss of legacies; in the ninth losses by sea; in the tenth dishonour and imprisonment; in the eleventh deep depression and false friends; in the twelfth sorrow, trouble and persecution from secret enemies. If the planet is strong—that is, well-dignified—these evils are much lessened.

Jupiter in the first house gives a good, happy and long life; in the second riches; in the third family affection and fortunate short journeys; in the fourth lands and inheritance with an honourable life and end; in the fifth many children who are good and affectionate; in the sixth faithful servants and fortunate dealings respecting cattle; in the seventh honourable marriage; in the eighth long life and natural death; in the ninth profitable sea voyages; in the tenth preferment and honours; in the eleventh faithful friends; in the twelfth victory over secret enemies. This, of course, means when the planet is strong in dignities; if weak the good will be somewhat abated.

Mars in the first house shows shortness of life and scars on the head or face; in the second poverty and troubles; in the third quarrels with kindred and dangers in travelling; in the fourth short life to the fathers; in the fifth disobedient children; in the sixth fevers, bad servants, and loss of cattle; in the seventh sensuality and unhappiness in marriage; in the eighth a violent death; in the ninth irreligion and losses at sea; in the tenth military preferment, but troubles from great dignitaries; in the eleventh false friends and loss of money; in the twelfth imprisonment. This is when Mars is afflicted, but if well-aspected these evils are somewhat abated.

The Sun in the first house gives honour, glory, and long life; in the second much riches, but great extravagance; in the third good brethren and fortunate journeys; in the fourth a noble inheritance and honours in old age; in the fifth few children, yet such as will be a comfort; in the sixth diseases of the mind; in the seventh a good wife, honourable adversaries, and sickness; in the eighth good dowry with the wife, but danger of a violent death; in the ninth gain by the sea, and ecclesiastical dignities; in the tenth gain from princes and noble women; in the eleventh distinguished friendships; in the twelfth powerful adversaries. This is if the Sun is well-dignified; if weak the good fortune is not so pronounced.

Zain n. adwan

Venus in the first house gives good health, but sensuality as regards the opposite sex; in the second riches by means of women; in the third, in a woman's horoscope, by means of lovers above her in rank; in the fourth inheritance; in the fifth many children; in the sixth illness from excesses; in the seventh a good and beautiful wife and very few enemies; in the eighth a good dowry with the wife and a natural death; in the ninth good fortune by sea; in the tenth honour and preferment through the means of some one of the opposite sex; in the eleventh sympathetic friends; in the twelfth freedom from the power of private enemies. This if Venus be strong; if weak the good fortune is less pronounced.

Mercury in the first house gives noble thoughts, graceful elocution, and love of art and science; in the second profit by intellectual work; in the third mathematical skill, swift and prosperous journeys; in the fourth the gain of an inheritance by craftiness; in the fifth clever children; in the sixth thieving servants and diseases of the brain; in the seventh a fomenter of quarrels, but a discreet wife; in the eighth death by consumption; in the ninth wonderful ability, especially in occult matters; in the tenth much preferment for ability; in the eleventh inconstant friends; in the twelfth secret enemies, but they will not much affect the destiny. This is when Mercury is well-dignified. If weak the good fortune is much lessened.

The Moon in the ascendant, or first house, shows the native will travel and will gain the favour of noble persons; in the second she sometimes gives unstable fortune, riches, and poverty alternately; in the third long journeys; in the fourth profit by travelling; in the fifth many children; in the sixth diseases of the brain, but good servants; in the seventh honourable marriage; in the eighth danger by drowning, but otherwise a long and healthy life; in the ninth many long sea voyages, inconstancy in religion, and love of art; in the tenth great honours; in the eleventh the friendship of noble personages; in the twelfth the common people will be the native's enemies and do him much wrong.

Zaid H. Adwan

The Dragon's Head when posited in the first house shows poverty; in the second a good estate; in the third honest kindred and fortunate journeys; in the fourth gain by travels; in the fifth long life and good children; in the sixth health and good servants; in the seventh a virtuous wife; in the eighth many legacies and a natural death; in the ninth prosperity at sea; in the tenth honour; in the eleventh faithful friends; in the twelfth open enemies.

The Dragon's Tail in the same places signifies the contrary in all things.

CHAPTER XI.

ON FORMING A GENERAL JUDGMENT ON A NATIVITY

Respecting the distribution of the doctrine of nativities, we are to consider first the *parents*, then the duration of life; the shape and figure of the body; after these the quality of the mind; then as to fortune in regard to honours as well as wealth. In succession to these the character of the employment; the questions relative to marriage, children, and friendships; then that concerning travel; and lastly, that concerning the *kind* of death which awaits the native from the configuration of the heavens at his birth.

The Parents.—In conformity with nature, says Ptolemy, the Sun and Saturn are allotted to the person of the father, and the Moon and Venus to that of the mother; and the mode in which these luminaries and planets may be found posited, with reference to each other as well as to other planets and stars, will intimate the situation of affairs affecting the parents.

Zaid n. adwan

If Mars should be in bad aspect to the Sun, the father will receive some injury to the face or die suddenly; but a long life is presaged if Jupiter or Venus be in any mode whatever configurated with either the Sun or Saturn.

If Mars be succedent to the Moon or Venus, or in quartile or opposition to them, or if Saturn be similarly aspected to the Moon only, and both of them be void of course or retrograde, or cadent, adverse accidents and disease will attend the mother; should they, on the other hand, be swift in motion and placed in angles, they portend that her life will be short or grievously afflicted.

Should the Sun be configurated, in any mode whatever, with the Moon or Venus, or should Venus herself be harmoniously configurated with the Moon, either by the sextile, the trine, or the conjunction, the mother will live long.

Concerning the duration of the native's own life, the Hylegliacal[9] places are, according to Ptolemy, the sign on the angle of the ascendant from the fifth degree above the horizon to the twenty-fifth degree below it; the thirty degrees in dexter sextile thereto constituting the eleventh house; also the thirty degrees in dexter quartile forming the Mid-heaven above the earth; those in dexter trine making the ninth house; and, lastly, those in opposition belonging to the angle of the west.

Among these places, the degrees which constitute the Mid-heaven are entitled to preference, as being of a more potent influence; the degrees in the Ascendant are next in virtue; then the degrees in the eleventh house, succedent to the Mid-heaven; then those in the angle of the west; and, lastly, those in the ninth house, which precedes the Mid-heaven.

He also holds that "the Sun, the Moon, and the Ascendant to be considered as the four principally liable to be elected to the office of prorogator"—or HYLEG.

zain n. adwan

These views are not adopted by the modern astrologers, but as this is a book *setting forth the ancient methods* it is needless to discuss the various objections made by them to this, as to some other of the theories laid down by Ptolemy.

Among the four prorogators already given, the Sun by day is to be preferred, provided he is placed in one of the Hylegliacal places, and if not, the Moon; but if the Moon also should not be so posited that planet is to be elected as Hyleg which may have most claims to dominion in reference to the Sun, the Moon and the Ascendant, which means that the planet should have dominion, in any one of the places where these are situated, by at least three dignities. If, however, no planet should be so circumstanced the Ascendant is then to be taken as Hyleg.

By night the Moon is to be elected as prorogator, provided, in like manner, she should be in some prorogatory place; and if she be not, the Sun; if he also be not in any prorogatory place, then that planet which may have most right of dominion in reference to the Moon, and the antecedent full Moon, and the Part of Fortune. But if there be no planet claiming dominion in the mode prescribed the Ascendant must be taken; in case a new Moon had last preceded the birth; but if a full Moon, the Part of Fortune.

If the two luminaries and also some ruling planet of appropriate condition should be each posited in a prorogatory place, then, provided one luminary may be found to occupy some place more important and influential than the others, that luminary must be chosen; but should the ruling planet occupy the stronger place, and have prerogatives of dominion suitable to the conditions of both luminaries, the planet must then be preferred to either of them.

When the Hyleg has been determined by the foregoing rules, then note whether it is supported by benevolent planets in good aspects towards it and free from affliction—that is, from evil aspects from evil planets—if so, the life is likely to continue and the constitution to be strong; but if the Hyleg, whether it be the Sun, the Moon, or the

Ascendant, be afflicted with evil planets and there be no assistance from good planets, the child will die in infancy: if there be some assistance from good planets, but yet the evil aspects exceed the good, the constitution will be weak and the first train of evil directions will destroy the life.

Concerning the disposition and quality of the mind, we must look principally to the planets in the Ascendant, the influences of which over mind and body have already been given in the chapter on the seven planets. We must, however, always bear in mind that Mercury has chief dominion over the mental faculties, whilst the sentient passions are governed by the Moon and the planet in the ascendant. The Moon well-aspected, that is, in trine, sextile, or conjunction to Mercury at birth, will give to the native excellent abilities, ingenuity, versatility and wit. Even the evil aspects of the square and opposition are better than no aspects at all, though these sometimes produce a cynical and obstinate nature.

The abilities of those born when Mercury is in "cazimi" (that is, within seventeen minutes of the Sun's centre) are of the highest order.

Mercury in conjunction with Saturn at birth gives clear judgment and a love of occult subjects.

Venus in good aspect with Mercury gives love of music and an artistic nature.

If Mercury and the Moon throw no aspect to each other and are afflicted by Mars and Saturn, the native will be liable to become insane.[10]

The fortune of wealth is determined by the Sun and the Moon; if they are in good position, that is, angular and well-aspected by the two luminaries, the native will be rich. If the Sun and the Moon are well placed, and if there be benefic stars in the Mid-heaven, the native will rank high in the world. If the contrary, the native never rises above mediocrity; and if Saturn afflicts the Mid-heaven, he meets disgrace. If Mars is

Zaid m. adwan

strong and in good aspect to the Sun and Moon, he will gain military glory. Jupiter on the Mid-heaven and the Sun and Moon in trine to each other, the Moon, having the trine of Jupiter, is one of the best positions for rising in the world. Jupiter in the tenth house will cause the native to do fairly well in the world; but Saturn in that house, if not extremely well-aspected, will bring him to shame and beggary.

Concerning the nature of employment, the dominion of the employment is claimed by the Sun and by the planet on the Mid-heaven. If Mercury should rule alone he produces writers, teachers of science, merchants and bankers; also, if well-aspected to Saturn and the Moon, astrologers and students of all occult matters; if Jupiter is in conjunction, then the native will be an orator, actor, or painter and his pursuits will lead him into the society of persons of rank.

Venus ruling makes wine-merchants, dealers in colours, dyes, perfumes, drugs, garments or apparel, &c.; if connected with Saturn, she makes persons have to do with amusement, players, jugglers, &c.; if with Jupiter, persons attending exhibitions and priests who have much personal decoration such as Catholic priests, bishops, &c. and they will gain by women. Mars ruling alone makes martial men and, if in Scorpio, Cancer, or Pisces, naval men.[11] The Sun joined with him, being near the Mid-heaven, or in aspect, makes persons dealing with fire or metals, the latter especially if in Taurus or Leo. If Mars be separated from the Sun, he makes shipwrights, smiths, agriculturists, stonemasons and carpenters.

If Saturn bear testimony in addition to Mars, persons become mariners, workers in mines, wells, vaults, &c., underground, keepers of cattle, cooks, butchers. If Jupiter join with Mars, they will be soldiers, innkeepers, tax-gatherers, mechanics. If Mercury and Venus become joint arbiters of employment, they produce musicians, dancers, poets, weavers and painters, &c. Jupiter in connection with them makes magistrates and senators and also teachers of youth. Mercury with Mars makes surgeons, statuaries,

boxers. If Mercury be more powerful, they will be scientific; and if Mars be stronger, they will be more violent and cruel in their practices.[12] If Saturn join these two, they will be thieves (especially if the Moon be in ill aspect to Mercury); if ☽ be in ill aspect to ♂, they will be robbers or assassins. If Jupiter join ☿ and ♂, they engage in honourable warfare and are industrious. If Venus and Mars rule together, persons will be dyers, workers in tin, lead, gold, silver and medical drugs.

The Moon regulating the employment and, separating from the Sun and forming an aspect with Mercury, inclines to the pursuit of astrology, spiritualism and magic.

Concerning Marriage, Ptolemy has laid down some very clear rules. He advises persons about to marry to have a care that the luminaries—that is, the Sun and Moon in their respective nativities—are in concord. It is of happy augury if the Moon in the bridegroom's nativity is in good aspect—that is, in trine or sextile to the Sun in the bride's nativity. The Square or Opposition aspects formed between the luminaries in the two nativities indicate discord and separation, and very evil effects follow if the malefic planets, Saturn and Mars, have a bad aspect to the Sun and Moon in both nativities. If Venus be with them the separation will be caused by adultery. Good planets, such as Jupiter and Venus, placed between the luminaries in both nativities, show much happiness.

In men's nativities the Moon must be chiefly considered in regard to marriage. Should she be in her first or third quarter at birth, the man will marry under thirty, or if older his wife will be a very young woman.

If the Moon be configurated with Saturn, she entirely denies marriage. If she should be in a sign of single form, such as Libra or Taurus, the native will marry only once, but if she should be placed in a double-bodied sign, such as Pisces or Sagittarius, the man will marry more than once.

If the Moon make application to the benefics, the wives will be good and true; but if she make application to evil planets, the wives will prove either bad or of a quarrelsome disposition. For example: If Saturn receives the Moon's application the wife will prove troublesome and morose, yet constant and industrious; if Jupiter receive it, the wife will be decorous, good and economical; if Mars, bold and refractory; if Venus, cheerful, handsome and agreeable; if Mercury, sensible, prudent and clever.

Women in whose nativities Venus is configurated with Jupiter or Mercury are virtuous and well-conducted; but, when Venus is with Mars and no other planet is there, women born under such aspects are liable to become licentious. Mars in square to Venus shows adultery.

For women the Sun is to be chiefly regarded in estimating their chances of marriage and happiness. If the Sun be oriental (*i.e.*, between the Ascendant and Mid-heaven, or between the Descendant and Nadir) the native will marry in her youth; or when old, to a young man. If the Sun be occidental, the native will marry late in life; or when young, to an old man. If the Sun be in a sign of single form, she will marry but once; if in a double-bodied sign, or configurated with several oriental planets (in one sign) she will marry more than once. If Saturn be configurated with the Sun, the husband will be steadfast, prosperous and industrious.

Jupiter configurated with the Sun gives a good, benevolent and honourable husband. "Mars," says Ptolemy, "gives a severe husband, void of affection and intractable." Venus gives an amiable husband of handsome appearance. Mercury gives one who is provident and expert in business and of a lively and cheerful temperament.

If Mars be separated from Venus and Saturn, yet have the assistance of Jupiter, men will lead virtuous lives. If Mars be configurated with Venus *only* men are of a licentious temperament.

Zain adwan

Saturn, when in the 7th house of a nativity, brings either unhappiness in marriage or early death of one or other of the married people. The Sun badly aspected by Saturn in the nativity of a woman and the Moon afflicted by the same planet in the nativity of a man, will bring trouble in love and marriage.

Description of the wife or husband.—The planet with the sign in which it is placed, which is posited near the cusp of the 7th house, must be taken to describe the person. If no planet should happen to be so placed, then we must go by the sign alone. Benefic planets in the 8th house show that the wife or husband will be rich; unfortunate planets show the reverse.

Children.—As regards the probability of having children, the 10th and 11th houses must be consulted and, should there be no planets in them, then the opposite, the 4th and 5th houses, must be considered. The Moon, Jupiter and Venus are said to be givers of children; the Sun, Mars and Saturn deny children, or give very few and those either die early, or are a source of trouble to their parents. Mercury either gives or denies according to the planets with which he may happen to be posited.

If the Sun and malefics be in barren signs or in masculine signs and in the before-named houses, there will be no children; but if they be in fruitful or feminine, or common signs, there may be children, but they will be delicate and short-lived.

If Jupiter, the Moon and Venus, are well-dignified in the 10th and 11th houses, the children born will attain rank and distinction in the world.

Friends and Enemies.—Persons born under the same sign of the zodiac are likely to be sympathetic; so also if the planet in the ascendant of one person's nativity is one which is friendly to that which rises in the ascendant in the other's. Thus, a person whose ruling planet is Venus would be attracted by one in whose ascendant Mars is dominant and a person whose ruling planet is the Moon rarely contracts a warm friendship with one who has Mars in the ascendant of his nativity and *vice versâ*. The friendships and

enmities of the planets have already been given in the chapter on the influences of the seven planets.

Mars in bad aspect to the Sun or Moon in the 7th house causes quarrels in married life.

Travelling.—The position of the Moon and Mars are here to be considered. If they should be in a cadent position the native will travel a great deal. The Moon in a watery sign causes much travelling by water. Ptolemy tells us that Mars in square or opposition to the Sun or Moon will cause much travelling in foreign countries. If the benefics are conjoined with the Moon, the journeys will be safe and pleasant; if with the malefics they will produce mischances and ill-health in travelling. Mercury ascending at birth, in a double-bodied or moveable sign, shows a great disposition to travel. If a malefic affecting the Moon should be in the watery signs of Cancer, Scorpio, or Pisces, shipwreck and even death by drowning may ensue during travelling.

Of the Manner of Death.—If the Hyleg and Ascendant should be well-aspected and if either Jupiter, Venus, Mercury or the Moon well-dignified should appear in the eighth house the native will die a natural death. If either the Sun or Moon should be badly aspected by Mars or Saturn in the eighth house it is significant of a violent or remarkable death. Saturn causes lingering deaths and Mars those which are sudden.

Saturn indicates death by chronic diseases, rheumatism, ague and paralysis.

Jupiter (when not well-aspected at birth) may become a promittor, or cause of death, by apoplexy, inflammation of the lungs, spasms, or gout.

Mars indicates death by acute or eruptive fevers, small-pox, all kinds of hæmorrhage, burns, suicides and wounds from iron, over which metal he presides.

Venus produces death by cancer, scurvy, dysentery, or wasting away and putrid diseases. If violence attends she causes death by poisoning.

Mercury kills by madness, epilepsy, coughs and obstructions. If violence concur he brings death by accident in sport or by robbers.

The Moon.—When the Ascendant or ☉ be Hyleg, the Moon will assist in causing death by cold phlegmatic diseases and if she be placed in ♋, ♏, or ♓, by drowning.

The Sun will assist to cause death by his ill aspects to the Ascendant or ☽ if they be Hyleg and then he acts like Mars, and if in *Leo*, will produce death by fire, if other testimonies agree.

The benefics cannot cause death of *themselves*; and even their ☌ aspects will frequently save life when they fall amidst a train of evil directions. But if the malefic influence is too powerful for them to avert, then they cause death in the various manners above described.

A Dogge Missing—where?

FACSIMILE OF A MAP OF A HORARY QUESTION FROM LILLY'S ASTROLOGY.

To face Chapter XII.

CHAPTER XII.

CONCERNING DIRECTIONS AND HORARY QUESTIONS

We have seen in the chapter on the judgment of a nativity that by the consideration of the position of the planets and of the Sun and Moon in the twelve houses, what the *general* fortune of the native will be in the whole course of his life; but the art of Direction measures out the time into years, months, weeks and days and thus informs us when we may expect in *particular* what is *generally* promised us in the nativity.

Directions are of two kinds, *primary* and *secondary*, and are based upon arithmetical calculations of the time of the events caused by the aspects of the significators (that is, of the Sun or the Moon), with the places of the planets. They are founded upon the familiarities of the stars amongst each other in the zodiac (*after the nativity*), and show, by calculations, the distance of the place of a significator at the moment of the nativity from the place it must reach before it can join the aspect, which distance is called *the Arc of Direction*. Some astrologers consider what are called "*Mundane Directions*," which are distances in the world measured by the semi-arc, and are wholly independent of the zodiac. These were invented by Placidus, but as Ptolemy does not treat of them they will not be considered here.

It must always be remembered that—in directions—the place of a planet, at the time of the nativity, is called the planet itself, although it may not be there when the significator arrives; thus, if we wish to direct the Sun to the conjunction of Jupiter, we must do so to the position which that planet occupied *at the moment* of the nativity. When the Arc of Direction is found the Sun's right ascension must be added to it, and the Sun will be the right ascension (without latitude) of that place in the zodiac at which, when the Sun arrives, the direction will be completed. For every day of the Sun's approach to this point a year must be added, and thus the time when the event is likely to happen is pointed out: these primary directions, however, cannot be depended upon to produce an event of great importance unless the secondary directions agree; but where the nativity is weak the primary direction alone is powerful enough to kill (especially if it should be opposed to the Hyleg), and misfortune will always happen if the positions of the planets, at the moment of birth, are unfortunate, *without* the coincidence of any secondary direction.

Secondary Directions are those daily aspects to the luminaries which happen after birth, every day of which is reckoned for a year, two hours for a month, thirty minutes for a week, and four minutes for a day.[13] Thus, whatever aspects take place in the *first*

day of the native's life will develop their effects in the first year and those of the second day in the second year, so that, should the native live fifty years, his secondary direction for his fiftieth year will arise from the aspects which took place on the fiftieth day after his birth. The ancient astrologers—particularly the Egyptians—used to predict the events of a nativity *wholly* from these secondary directions,[14] in which the Moon should be chiefly considered; for in those days on which she comes to an evil aspect with the malefics, Saturn or Mars, the years corresponding to those days will be peculiarly unfortunate and dangerous to the native; and where, on the contrary, the Moon is well-aspected to the benefics, the years corresponding to those days will be very fortunate: a good direction gives prosperity in that matter which the significator indicates; thus we direct the Sun to signify the native's preferment or disgrace, his good or bad health, and the favour or disesteem of great personages.

The direction of the Moon refers to the nature of the native's journeys, whether prosperous or the reverse, his marriage, his wife, his women friends and kinsfolk.

The direction of Saturn signifies the native's inheritance, buildings, possessions, and also his fears, jealousies and mistrusts.

Jupiter is directed as regards glory, renown, riches, children and religion.

Mars is directed for the native's law-suits, animosities and victories; he also shows the estates of brethren.

Venus is directed for marriage, love and pleasure and all matters in connection with women.

Mercury is directed for a knowledge of the amount of wit, understanding, trade, industry, and journeys of the native; also for distinction in scholarship and all intellectual pursuits.

zain adwan

The Horoscope or Ascendant is directed to signify the life, affections and manners of the native.

The Mid-heaven's direction affects the position and career of the native.

If the directions are to good aspects of benevolent planets, they signify prosperity both of mind and body, cheerfulness and all manner of earthly happiness; but if the horoscope should have directions to the ill aspects of the malefics, Mars or Saturn, then evil is to be expected of the nature given by the malevolent star. If directed to the good aspects, such as the trine or sextile of these evil planets, the misfortune is not so great, and even in some instances good may be predicted. As, for example, the horoscope directed to the trine or sextile of Mars gives preferment by arms; the same aspects towards Saturn would indicate success in building or in mines, or some calling connected with metals.

The occasional differences in the life, tastes, health, marriage and pecuniary affairs of twins, born within ten or twenty minutes of each other, are accounted for by the fact that at the birth of the first child the last degree of a sign may ascend with planets therein, or a planet in the 2nd house at 5 p.m. may be in the 1st at 5.15 p.m. and the early degrees of another sign may be exactly on the ascendant at the birth of the second child.

A planet may reach the M.C., or any other of the four cardinal points at, say, 10 p.m. and ten minutes later have passed off, when its powers would have greatly diminished. Though the signs rise and set at the rate of 15° per hour, in our latitude from 50° to 60° North, it often happens that 30° will ascend in fifty-two minutes.

Horary questions are questions asked at a certain time when a person feels anxious concerning any undertaking or impending event. A figure or map of the heavens, like that erected for a nativity, is drawn out for the minute in which the question is asked; and, if the astrologer be skilful, and the querist sincere—that is, not putting the question

zaid n. adwan

from frivolous motives—the answer will, in general, be true, for the whole is the effect of that sympathy which pervades all nature and which is the keynote of all divination under whatsoever form it is practised.

In horary questions the sign ascending and its lord represent the querent, and to these the Moon is added and must be considered with the lord of the ascendant.

The house to which the thing belongs—about which enquiry is made—is the significator of that person and thing, and every other house and its lord are to be considered according to their respective significations, so as to indicate the means and persons by which the event, about which the enquiries are made, will be accelerated or retarded.

The dates of events are regulated by the signs and angles. For example, should the significator of the event be in a movable sign and an angle the event will come to pass in the same number of days as there are degrees between the significator's aspect and the star to which it is directed if the aspect be by *application*; if by *separation*, the thing will *not* take place at all. In one of the succedent houses movable signs give months, common signs years and fixed signs bring about the event, after much delay, and when all hopes of it are past.

Significators in any of the cadent houses seldom do anything and, should they bring about an event at all, they do so after much waiting and with much trouble and vexation.

The matter of horary questions is very well treated in Lilly's *Grammar of Astrology*, published in 1647, and, by way of explaining the manner in which this branch of astrology is worked, we give a *fac-simile* of a map of a horary question to be found in this book, with (verbatim) Lilly's method of dealing with that particular question.

Judgment of the Figure given in Plate.—"Living in London, where we have few or no small cattle as in the country, I cannot give example of such creatures, but I once set

the figure preceding concerning a Dogge (which is in the nature of small beasts), which dogge was missing. The question to me was what part of the city they should search and if he should ever be recovered.

"The querent was signified by the sign ascending and the lord thereof, for, in his person, he was Saturnine and vitiated (according to the Dragon's Tail in the ascendant) in his nature, mind and understanding—that is, he was deformed in body and of a covetous disposition. The sign of the sixth house and his lord signifies the dogge, for that sign stands for sheep, hogs and small cattle.

"The sign of Gemini is west, and by south the quarter of the heaven is west; Mercury (the significator of the dogge) is in Libra, a western sign, but southern quarter of heaven, tending towards the west; the Moon is in Virgo, a south-west sign, and verging towards the western angle. The strength of the testimonies being thus examined I found the plurality to signify the west, and therefore I judged that the dogge ought to be westward from the place where the owner lived, which was at Temple Bar, wherefore I judged that the dogge was about Long Acre, or the upper part of Drury Lane. In regard that Mercury (the significator of the beast) was in a sign of the same triplicity as Gemini the ascendant, which signifies London, and applied to a trine aspect of the cusp of the sixth house, I judged that the dogge was not out of the lines of communication, but was in the same quarter, of which I was more confirmed by the trine of the Sun and Saturn. The sign in which Mercury appeared was Libra—an airy sign; therefore I judged that the dogge was in some chamber or upper room, and kept privately, or in great secrecy, because the Moon was under the beams of the Sun; and Mercury, the Moon and the Sun were in the eighth house: and because the Sun on the Monday following would apply by trine to Saturn, the lord of the ascendant, and the Moon to trine of Mars having exaltation in the ascendant, I intimated to the owner of the beast that, in my opinion, he should have his dogge again, or news of his dogge or small beast, upon the Monday following, or near that time, which was true; for a gentleman of the querent's

acquaintance sent home the dogge the very same day, about ten in the morning, who, by accident, coming to see a friend in Long Acre, found the dogge chained up under a table, and, knowing the dogge to be the querent's, sent him home as above said, to my very great credit," and no doubt also to the great satisfaction of "the dogge" himself.

CHAPTER XIII.

SOLAR HOROSCOPES[15]

JANUARY.—AQUARIUS

The influences of this sign last from the Twenty-second of January to the Twenty-first of February.

The man born under this influence will be of medium stature, good genius and a great speaker. He will achieve what he desires and will become famous in his own country.

He will be subject to melancholy, very religious and of a highly conscientious nature. The stars, however, destine him to pass through much poverty in his youth and he will have other troubles in the matter of deaths of relations and friends before he is thirty. He will travel much and, in his early youth, he will suffer from illness. He will be much influenced by women to his own detriment. He will lose his first wife and will marry twice, but the second marriage will not be very fortunate. At thirty he will be very seriously ill, but will recover and live on to about sixty-four years.

The woman who is born at the above-mentioned dates will have a charming and expressive face; her eyes will be soft and beautiful in shape and her hair of a medium brown colour, neither very dark nor very fair. In character she will be slightly melancholy and of a romantic turn of mind. She will be happy in her marriage. She will

zain.adwan

have a serious illness at fifty, but will recover from it through the affectionate care of her husband, and will live to a good old age, surrounded by her children's children.

FEBRUARY.—PISCES

The influences of this sign last from the Twenty-second of February to the Twentieth of March.

The man who is born under the influence of this sign will be above middle height, his chin will be fleshy, his eyes blue and his complexion rather colourless. His forehead will be low and broad and his eyes will express much kindness and goodness of disposition. He will be very fond of aquatic pursuits and take great delight in angling. He will not be studious, for he has not much perseverance, but he will take delight in conversation of an instructive order. He will not be much of a talker and will be slow to give his opinions on any subject. He will be of a luxurious temperament and will be much influenced by women. He will be economical in his household expenses, but will spend money freely on his own pleasures out of his family circle. He will be fond of travelling and will be more fortunate in other places than in his own country. He will be ingenious and of good counsel, yet wiser for others than for himself. He will lose his wife early in life, but will not marry again, yet this more from indolence than constancy of feeling.

The woman born at this time will be fairly good looking; her eyes will be light blue and she will have a fair complexion and a dimple in the right cheek. She will be of a good disposition and kind to the poor; but yet she will be self-indulgent and much given to luxury of all sorts. She will marry twice and have many children, but the stars do not promise her much happiness. She will die at sixty-eight.

MARCH.—ARIES

zaid n. adwan

The qualities given by this sign of the Zodiac last from the Twentieth of March to the Twentieth of April.

The man born under this sign will be of medium stature, of fierce countenance, with an aquiline nose, quickly moving eyes and a strongly marked dimple in the chin. His hair will be of a reddish tint, his forehead broad and his complexion florid. He will be a loud talker and have much inclination for women and also for the pleasures of the table. He will be fond of field sports and very courageous. He will be subject to accidents, both from fire and from four-footed beasts. He will be capricious in his affections and will suffer much from his affairs with women in his youth, but will grow wiser towards middle age. He will not marry. At fifty he will lose much money and will fall into poverty, and thus become alienated from the friends of his youth. His life will not be prolonged much beyond fifty-five years.

The woman born at this time will have a florid complexion, large round-shaped eyes and a square chin. She will be of middle height and rather strongly made. She will be quick-tempered, strong-willed, very courageous and rather selfish. She will marry at twenty-three, but will not have many children. She will be a widow in middle life and will marry again within a year of her first husband's death. She will die suddenly by an accident in her fifty-sixth year.

APRIL.—TAURUS

The influences of this sign last from the Twenty-first of April to the Twenty-first of May.

The man born under this sign will have full lips, a short throat, and a mole at the back of his neck. He will be subject to sudden fits of anger and will be fierce and cruel. He will be fond of women, but will not be much liked by them and will suffer much in consequence. He will be ambitious, fortunate in business and energetic. He will not be very prudent in speech and will often get himself in trouble by over-

zain n. adwan

communicativeness. He will marry a rich wife and will acquire much money by legacies from her relations. He will be very ill at forty, but he will survive it and come into much riches soon after it. His life will go on to about sixty-two, when he will die of much the same illness which he had at forty.

The woman born at this time will be graceful and well formed, with luxuriant hair and a full and well-formed mouth. She will have a good complexion and will have fascinating manners, so that she will much attract men. She will run great risks both from fire and water, and she will be subject to weakness of the eyes to such excess that towards the end of her life she will have reason to fear blindness, but she will escape this calamity. Although she will have many lovers she will only marry once, for her husband will survive her. She will have many children and they will all live. She herself will die before sixty.

MAY.—GEMINI

The influences of this sign will last from the Twenty-second of May till the Twenty-first of June.

The man born under the influence of this sign will be subject to ulcers and all skin diseases. He will be tall, well formed and of florid complexion. He will be much liked for his amiable qualities and will govern his family well. He will travel much in foreign countries and will acquire many beautiful things in the course of his travels. He will be attentive to women, very conscientious, gracious and valiant. He will not be at all given up to luxury, but will be of a pious and self-denying temperament. He will be bitten by some venomous reptile, yet will not die of the wound, but will recover entirely from it in a short time. He will be falsely accused of some sin and will be imprisoned for it; but he will come out victorious and his innocence will be acknowledged by all. His marriage is uncertain.

The woman who is born at this time will be fluent of speech, gracious in manners, witty and intelligent, but rather sensitive in temper. She will be small of stature, slight in figure and of a fair complexion. She will have well marked yet delicate eyebrows, brilliant eyes and small white teeth; her hands will be slender, with pointed fingers. By reason of her grace and wit she will be much loved, but she will not marry until she is twenty-five. She will be passionately loved by her husband, but she will not return his affection. She will have very few children who will not live beyond childhood. She herself will die at sixty-seven.

JUNE.—CANCER

The influences of this sign last from the Twenty-first of June to the Twenty-first of July.

The man born under this sign will be of medium height and will have light hair and eyebrows. He will be given to deceit in his manners with women and will be very inconsistent, yet always with such gracious manners towards them that he will be much beloved by them. He will travel much, and will suffer many misfortunes in the way of accidents. He will in middle age lose much money through the misconduct of his brothers, who will, by their extravagance, spend all the father's money and thus leave only a poor inheritance. He will occupy himself with agriculture and be successful with it. At forty he will suffer from a very serious illness and his life will probably end at forty-eight.

The woman born at this time will have large grey eyes, full lips and an abundance of soft, rather colourless hair. She will be fond of luxury and ease, and will be much given to the pleasures of the table, and will eat much and drink more. She will marry early, but will not agree with her husband by reason of her own inconstancy. She will be married three times, and will get on better with her last husband than with the two

others. She will have several children, but they will all be of a sickly constitution. She herself will have a very serious illness at seventy which will cure her of all her troubles.

JULY.—LEO

The influences of this sign extend from the Twenty-first of July to the Twenty-first of August.

The man born under this sign will be of middle height, but more inclined to be tall than short; his hair will be of a red colour, and his eyebrows will be well marked and much arched in their form. He will be valiant, hot tempered, very talkative, somewhat boastful, but pleasant and jovial in his manners. He will be a great admirer of women, but not constant in his affection. He will marry once, but not the woman he so much loves.

The woman born at this time will be tall, with bright hair of a reddish gold colour, grey eyes, with a bold fierce glance, and long features. Her nose will be aquiline and the face a long oval. The lips will be full but firmly closed and the teeth good and large. She will be quick of temper and difficult to please, fond of pleasure and very ambitious of shining in society. Her great desire for admiration will cause her to be much talked about—not always in a manner pleasing to her husband. She will marry early. She will lose her husband in early youth and will marry again soon after her widowhood. She will be much subject to illnesses through the blood, and at forty-eight she will have a very serious illness; but she will recover and live another fifteen years, but her life will always be full of anxieties and troubles.

AUGUST.—VIRGO

The influences of this sign last from the Twenty-second of August to the Twenty-third of September.

Zaid Adwan

The man born under this influence will have an abundance of hair and will have a large chin and a good complexion. He will be ambitious, enterprising, and very valiant, but a little capricious. He will suffer much illness and, when he is about thirty years of age, he will be menaced by death or imprisonment, yet he shall escape both evils. He will be of a sympathetic and benevolent disposition and will give good counsel to his friends. He will have a beautiful wife whom he will tenderly love, although she will not return his affections.

A woman born at this time will be graceful and charming, with a well-formed face, an agreeable expression, small mouth and well-proportioned figure. Her voice will be one of her charms, and will be clear and soft and singularly harmonious. She will be much loved and admired for her wit, and will show much taste for music and dancing. She will have fairly good health, and her beauty and charm of manner will make her much sought after in marriage, but she will not accept any of her numerous lovers until after her twenty-second birthday. She will be much loved by her husband, and being inclined to be devout, she will educate her children in the fear of God. She will die at sixty-nine.

SEPTEMBER.—LIBRA

The influences of this sign last from the Twenty-third of September to the Twenty-third of October.

The man born under this sign will be fluent of speech and his voice will be sonorous and will sound angry even when he is not so. He will be wise and prudent and will be much esteemed by good men. He will be just and honourable in all his dealings and will acquire the respect of all who know him for his conscientious dealings with his fellow-men. He will marry twice. His second wife, whom he will marry when he is turned forty, will be extravagant, and will so worry him by spending all his substance, that she will bring on his death before he is fifty.

zaid n. adwan

The woman born at this period will be, say the astrologers, cheerful and of a kindly disposition. She will be of a lively temperament and will easily learn both music and dancing and will excel in both. She will be amiable, very caressing in manner and much loved by all who know her. She will marry twice. Her first husband will be rich and of mature age and very prudent. The second will be young and will soon spend the greater part of the money left her by her first husband. She will be gay, fond of pleasure and rather a coquette, which will much displease the second husband. She will be rather given to gambling and will lose money in this way, which will cause her much discomfort and anxiety in her latter years.

OCTOBER.—SCORPIO

The influences of this sign will last from the Twenty-second of October to the Twenty-first of November.

A man born under this sign will be short and broad in figure and ungraceful in his movements. He will be dark in complexion; but the hair will be of a red-brown colour, the eyebrows thick and meeting over the nose. He will be prompt in judgment, but very wily and inconstant, promising one thing and doing another, so much so, that those who have once had dealings with him will never again have confidence in him, knowing how likely he is to deceive them. He will be of a perverse and irritable temper, which will cause him to have many enemies; and notwithstanding all his acuteness, he will always be poor. He will travel much and will lead a somewhat vagabond life. He is very unlikely to marry, and he will probably die a violent death.

The woman who is born under the influence of the Scorpion will be of a reddish colouring and of middle height and strongly built. As regards her character, she will be affable, much beloved by her relations, fond of pleasure, yet very energetic in the discharge of her household duties, sensitive in temper, a little revengeful and very ingenious and of quick judgment. In her youth she will have much trouble from

lawsuits, but she need not fear the result, for as she is pious God will always protect her. She will only marry once, at about her twenty-sixth year, and will die at sixty-eight. She will have no children.

NOVEMBER.—SAGITTARIUS

The influences of this sign continue from the Twenty-second of November till the Twenty-first of December.

The man born under this sign will be of pale complexion and he will have long features and dark hair and eyes. He will be prudent, studious and economical. He will see many foreign countries and will gain much money in his youth, by reason of which he will excite the envy of his friends. He will receive much injury from a relative, who will endeavour to prejudice people against him, but he will always be well received and much liked in society. He will be generous to his friends, but he will be badly recompensed for his kindness. He will be persevering in his profession and will attain a good position in it. He will be subject to internal complaints, but will live long. He will be untrue to his wife, but he will be careful that she does not know it. He will have several children, but they will be no comfort to him, as they will be always ungrateful to him.

The woman who is born at this time will be well formed, with luxuriant hair and well-marked and rather arched eyebrows; her forehead will be broad and her intellect good, but her temper easily irritated and over sensitive, especially where her affections are concerned. She will be timid, very constant both in love and friendship, generous in her affections, yet very ill-requited in this respect. She will marry at twenty-six and will have many children. She will suffer much from the evil tongues of false friends, who will malign her to her husband, but her innocence will be made known and in the end she will be fully justified. She will live to sixty-eight.

DECEMBER.—CAPRICORNUS

Zaid n. adwan

The influences of this sign last from the Twenty-first of December to the Twenty-second of January.

The man born under this influence will be of good complexion, his voice will be clear and bright and he will be fluent of speech. He will have a mole on his chin or on his right arm. He will be very much influenced by women and will be a great lover of luxury. He is likely to be bitten by some mad animal and he is also menaced by many illnesses of the eyes and eyesight. He will be much deceived by a woman who will cause him much injury.

The woman born under this sign will be amiable, with an agreeable countenance, a clear voice and a well-formed body. She will be twice married. Her first husband will much love her. He will be a poor man, but of a very conscientious nature and much respected for his straightforwardness of character. Her second husband will be much richer and of a gay and pleasure-loving nature, but he will not be so affectionate as the first. She will suffer much from melancholia, and when she is thirty she will have a very serious mental illness; but, by the grace of God, she will recover from it and live until she is forty-seven.

CHAPTER XIV.

APHORISMS CULLED FROM THE WORKS OF PTOLEMY AND OTHER ANCIENT ASTROLOGERS

Whosoever may be adapted to any particular event or pursuit will assuredly have the star indicative thereof very potent in his nativity.

If Virgo or Pisces be on the ascendant the native will create his own dignity; but if Aries or Libra be there he will cause his own death.

zaid n. adwan

Venus gives pleasure to the native in that part of the body which may be ruled by the sign she occupies. It is the same with other stars.

Should a disease begin when the Moon may be in a sign occupied at the birth by some malefic, or in quartile or opposition to any such sign, such disease will be most severe; and if the malefic also behold the said sign, it will be dangerous. On the other hand, there will be no danger if the Moon be in a place held at the time of birth by some benefic.

In all horary questions remember that there is no affliction to the Moon so great as when she is in conjunction with the Sun; the ill aspects for the malefics must affect her, but no evil aspect is so powerful as her conjunction.

Mercury in trine or sextile to the Moon gives the capacity for acquiring foreign languages. In bad aspect to the Moon makes the native envious, sarcastic, ill-natured, given to lying and thieving.

Saturn in trine or sextile to Venus shows much power of attachment to wife and family. In a woman's nativity this is very good, as it indicates purity.

Those born near noon are generally successful in life, owing to the Sun's influence being then most powerful. Those born near midnight are by no means so fortunate as those born at midday, and it is a singular peculiarity in such nativities that the most remarkable events of their lives take place *after* their thirtieth year, and they are also certain of some kind of a name after death, meritorious or otherwise, according to what their horoscope declares. Persons born near midnight are very imaginative, and subject to see visions, dream dreams, and to be believers in the unseen world.

In all travels the Moon is to be considered, for she is a general signifier of journeys, whether by sea or land.

Zaid n. adwan

When the moon is besieged between Mars and the Sun in a nativity, it argues a short life to the native.

Mercury, if posited in one of the houses of Saturn, in trine or sextile to that planet, gives excellent understanding; and if the moon be also well-dignified, the native is much given to the study of occult science, and will have much renown in that particular.

Those born with the Moon powerful in their horoscopes would do well to be guided by her aspects in their daily avocations. If she should be in trine or sextile to Jupiter, it is a good day to seek favours of the great, or to make arrangements with employers. When she is in trine or sextile to Mercury, all intellectual matters taken in hand will be likely to prosper. When she is so aspected to Venus, matters undertaken with reference to love, marriage, or friendship will have a happy issue. When she is in square or opposition she would have, of course, the contrary effects.

The Sun and Moon in conjunction with Mercury give to the native great intellectual abilities.

Those who have the benevolent planets, Jupiter and Venus, well posited in either the ascendant or the mid-heaven at birth will always be much beloved during the whole course of their lives.

He who is born with the sun in trine to Jupiter is fond of rule, and very famous in his generation.

Venus in square to Saturn at a birth causes the native to be sensual and given to unnatural vices.

All the planets, or most of them above the earth, make the native eminent and famous, and if all should be well-dignified, he will—like a comet—outshine all others in the world's esteem. If, on the contrary, all the planets are under the earth at a birth, the native will be of a falling fame and fortune, or if they promise by their natures honour,

zain. adwan

dignity and fortune (that is, if they appear essentially dignified in nocturnal genitures), these good things will only come in the latter part of the native's life.

Jupiter in conjunction with the Moon in a watery sign gives drunkenness.

Venus in conjunction, trine or sextile to the Moon, gives happy marriage, but in square to the Moon, prodigality, indolence and drunkenness.

Saturn in square to Mars means a malicious and murderous temperament, and liability to imprisonment.

It is advantageous to make choice of days and hours at a time well constituted by the nativity. Should the time be adverse, the choice will in no respect avail, however favourable an issue it may chance to promise.

A sagacious mind improves the operation of the heavens, as a skilful farmer by cultivation improves nature.

zaid n. adwan

Part II.

CHIROMANCY

"God has placed signs in the hands of all men, that every man may know his work."—Job xxxvii. 7 (*St. Hierom's Translation*).

CHAPTER XV.

CHIROMANCY AND ITS ORIGIN

Chiromancy is a science which teaches us to read not only the character but the whole destiny—for good or evil, the length of life and often the manner of death of a man by the lines and marks to be seen in his hand. This study is sometimes called Palmistry, in which case, however, it properly refers *only* to a judgment formed from what appears in the palm of the hand, whilst Chiromancy (taken from the word *Cheir*, a hand, and *Manteia*, divination) signifies the revelations made by the hand, taken as a whole. Chiromancy is nearly as ancient as astrology, with which it is *indissolubly* connected, for the hand represents, as has been before said, a natural horoscope, which is placed upon it at the time both of the conception and the birth by the influence of the stars. The seven planets are all represented in the hand and also the twelve signs of the zodiac, so that the casting of a nativity is needless, as by simply examining a hand by the light of Chiromancy we can indicate what planets have been powerful at the time of birth, and what, therefore, will be their effect for good or evil over the existence; and we can also find the dates of the principal events of the life. We find many allusions to this subject in the Bible, and still more in the ancient Kabbala.

The Holy Kabbala, as it was called by the Magi, must not be confounded with what is called "The Black Art"; it is, on the contrary, the quintessence of reason and morality as they were understood by the ancients and contains that traditional science of the secrets of nature which, from age to age, is borne towards us as the wave is carried by the tide to the shore; but it has been transmitted obscurely, because the doctrines of the Kabbala were known only, in those early ages, to the adept and the initiation, later on, of neophytes was only yielded after a series of severe and terrible ordeals, whilst the revelation of its mysteries to the uninitiated was punished by death.

The necessity of silence was, in fact, one of the principal tenets of the Kabbala and is represented, in the figure of Adda-Nari,[16] by the position of the fingers of the hand holding the flowering branch of Abundance; the thumb and the first two fingers, which in Chiromancy represent *will*, *power* and *fatality*, are held open; whilst the third and

fourth fingers, representing light and science, are closed. This was meant to indicate to the good—the initiated—that they would have, when united, strength and will to direct Fate; but that they must keep hidden from the wicked and ignorant both light and science. It must, however, in justice to the ancient Kabbalists, be suggested that their inculcation of silence probably arose, not so much from a desire of domination, but rather from the fact that, feeling themselves superior in knowledge, they thought they were obeying a divine law in refusing to the wicked those lights which, when possessed by them, led, as perhaps they had sometimes found, to error. We, seeing things in a wider light, give, or try to give, equal knowledge to all, without submitting the ignorant to the ordeal of initiation to prove their worthiness as recipients; but, after all, it amounts to much the same thing—give to all men truth and light in abundance, but all will not profit by it. We see this every day in our college system; the lesson is the same for all, but it is only the few who profit by it; and although we appear to be obeying a divine law in opening the way of light and life—the life of knowledge—to all, as God makes His sun to shine on good and bad equally, still we can, in some sort, understand the feeling of the ancient Magi, whose motto was: "Know, Dare, Will, but *keep Silence*."

CHAPTER XVI.

THE PRINCIPAL LINES IN THE HAND AND THE MOUNTS

In the plate belonging to this chapter we give a hand on which are marked the principal lines seen on the palm; three of which, viz., the Line of Life, the Line of Head and the Line of Heart, are found in a clearer or fainter degree on all hands, but which vary, as regards their relative position, in every hand. The first and largest, that which encircles the thumb, is called the Line of Life; by the length, colour and evenness, or the reverse, of this line the length of life is indicated, and also the illnesses and accidents by which the life is menaced in running its course. The line immediately above it, crossing the

palm of the hand, is the Line of Head; by it we are to judge of the intellectual powers. Above it is the Line of Heart, from which we form an opinion of the strength of affection, or the want of it, in the native.

The lines which are not always to be found are the lines going from the wrist to the finger of Saturn, which is called the Saturnian line, and which shows the events of the life; the Line of the Sun, which goes towards the finger of the Sun and which indicates success in art, literature, or the pursuit of riches; and the Line of Health, which goes from the wrist to the finger of Mercury: this line is often absent in a hand.

All these lines will be more fully discussed further on; at present it is only necessary to name them in order to explain the plate belonging to this chapter.

At the base of each figure there is a mount, more or less developed, on every hand. Now, each of these mounts corresponds with one of the planets from which it has received more or less influence, according to its development, and the signs or marks to be found upon it.

It will be seen also, from the plate, that the ancients gave to each finger the name of one of the planets, thus:—

The first finger represented Jupiter, the mount at its base being called the Mount of Jupiter.

The second, Saturn, the mount at its root being the Mount of Saturn.

The third, the Sun, the mount below being the Mount of the Sun.

The fourth, Mercury, the mount at its base being called the Mount of Mercury.

The thumb is sacred to Venus, and the root of the thumb is called the Mount of Venus.

It will also be seen that the planet Mars (although no finger is dedicated to it) is twice represented in the hand, along the side of the palm by the Mount of Mars, and in the

zain n. adwan

palm, between the Line of Life and the Line of the Head, which is called the Plain of Mars.

The Moon is only represented by the Mount of the Moon, at the lower part of the palm on the opposite side of the hand to the thumb.

When these mounts are well in their places, and clearly but not too strongly defined, they give the qualities of the planet they represent; but when any mount is not well marked, or even, as frequently happens, is quite deficient, there is a want of the qualities shown to exist where the mount is clearly defined. If the mounts are not only ill-defined, but represented by a cavity, that cavity would indicate the existence of qualities which are the reverse of those indicated by the mount; whereas an exceeding development would denote an excess of the qualities given by the mount.

Thus the Mount of Jupiter, which is immediately under the index finger, when fairly developed, indicates noble ambition, will-power, love of nature, kindliness, generosity, religion and happy marriage. When in excess—that is, when the mount is so large as to invade that next it—the Mount of Saturn—it gives superstition, exaggerated pride and domineering self-assertion. The total absence of this mount (which is sometimes, but rarely, seen) indicates coldness, selfishness, irreligion and that want of dignity which is produced by the utter absence of self-respect.

The Mount of Saturn is found immediately beneath the second finger, which the ancients assigned to Saturn, the planet of Fatality. Saturn gives extreme misfortune, or extreme good fortune, according to the development of the mount and the signs and lines to be seen upon it, and the course of the Saturnian Line, or Line of Fate (of which we will speak further on), in the palm of the hand. This mount also denotes a tendency to occult science. Those born specially under the influence of Saturn are timid, lovers of solitude, and very seldom marry, but are very persistent in their affections when they do love.

Saturn, when well developed, gives prudence, wisdom and, to a certain extent, success; when in excess it gives sadness, taciturnity, asceticism, dread of the after-life and yet, sometimes, a predisposition to suicide. The total absence of the mount indicates an insignificant existence.

The Mount of the Sun is placed at the root of the third finger, which was sacred to the Sun; when this mount is well developed it indicates love of art and literature, which shows itself (according to temperament) in poetry, painting, sculpture, or music; it gives also religion of the æsthetic, tolerant sort, grace, riches and celebrity; in excess it gives love of show, frivolity and vaingloriousness. The total absence of the mount means a thoroughly material existence; absence of all taste for art—a life without colour, a day without sunlight.

The Mount of Mercury is found at the base of the fourth finger, and, when well defined, indicates intelligence, success in science and in occult studies, the love of work and activity, both of mind and body and eloquence; in excess it gives impudence, theft and falsehood: absence of the mount indicates no aptitude for science, no intellectuality—a negative existence. Of course, should the Mount of the Sun be well defined, the last quality would be overridden by the success which that indicates.

The Mount of Mars is at the side of the hand opposite the thumb, just below the Mount of Mercury, and, when well developed, indicates courage, ardour and resolution; in excess it gives cruelty, anger, revenge and tyranny: the absence of the mount gives cowardice and want of self-command.

The Mount of the Moon is found immediately below that of Mars, and, when well developed, gives imagination of the dreamy, sentimental order, gentle melancholy and love of solitude; in excess it gives morbid melancholy, caprice and fantastic imagination: the absence of the mount indicates want of poetry in the nature, positivism.

The Mount of Venus, which is formed by the root of the thumb, indicates, when fairly developed, love of the beautiful, melody in music, the desire of pleasing and sensuous tenderness; in excess it gives love of material pleasures, coquetry, inconstancy and (when other signs, afterwards to be explained, are also seen in the hand) extreme sensuality.

Each planet has a special influence over certain parts of the body. Jupiter governs the head and lungs; Saturn, the spleen and ears; the Sun, heart, eyes and arms; Mercury, the liver and legs; Mars, the head and throat; the Moon and Venus, the lower parts of the body. Any excess in the length or size of the fingers or mounts argues a tendency to disease in the organs represented by that finger or mount. When a mount is—instead of being high—broad and full, it gives the same indications as if it were high; if much covered with lines it shows an overabundance of the quality of the mount, and is equal to an excess of height. *One* deep perpendicular line upon a mount is a fortunate sign; *two* show danger of too great force of the quality; and *three* give misfortune arising from excess of the qualities of the mount. Crossway lines on the mount always denote obstacles. Some old Italian writers affirm that fine cross lines on a mount signify wounds to that part of the body over which the mount on which they are seen has influence.

The mounts are often irregularly placed. If one should lean towards the other, it absorbs some of the qualities of the mount which it invades.

To face Chapter XVII.

CHAPTER XVII.

THE LINE OF LIFE

The ancient Chiromancists divided the Line of Life into ten compartments (see plate), each representing ten years of life, and thus they were enabled to prognosticate at what date in the life the illnesses or dangers indicated by the form or colour of the line would be likely to happen. This plate is copied from one in the Sieur de Peruchio's interesting work, *La Chiromance*, published in Paris in 1657.

It will be noticed that the mounts are here indicated by the astrological symbols of the various planets they represent, Mars being placed on the Plain of Mars, and again on the Mount of Mars, which, as we have already seen, lies immediately below the Mount of Mercury, It will also be seen that the signs of the zodiac are also represented on the hand: Aries (March), which begins the astrological year, is placed at the base of the hand, close to the Mount of Venus; Taurus (April) is on the Mount of Venus; Gemini (May) is at the base of the Mount of Jupiter. These represent the spring-tide of the year, and also of life: therefore they are placed on and near Venus, which planet represents happiness and enjoyment. The signs Cancer (June), Leo (July) and Virgo (August) represent the second age, which is given to the accumulation of riches and honours: so these signs appear on the finger of Jupiter. In the third age a person is supposed to enter upon the enjoyment of dignities, therefore Libra (September), Scorpio (October) and Sagittarius (November) are on the third finger, that of the Sun, which is supposed to accord position and reputation. The last months of the astrological year are thus placed: Capricornus (December) is beneath the Mount of the Sun; Aquarius (January) is on the upper part of the Mount of the Moon; and Pisces (February) will be seen at the base of the Mount.

When the Line of Life is long, well-formed, slightly coloured and goes all round the thumb, it indicates a long life and free from serious illness; but when the line is wide and pale in colour, it indicates bad health; when it is short, it means early death.

If the Line of Life is broken on one hand, but is marked in a continuous line on the other, these signs indicate an illness of a very serious nature; but if the broken line should appear in *both* hands, it means death at the epoch corresponding with the place on the line where the break occurs. When the Line of Life is not clearly defined, but is formed by a sort of chain of small lines, it indicates continuous small illnesses.

zain.adwan

When the Line of Life, instead of starting from the side of the hand, takes its rise in the Mount of Jupiter, which is sometimes, but rarely, the case, it indicates a life of successful ambition, honours and celebrity—qualities given by the influence of Jupiter.

If the Line of Life joins the Line of the Heart and the Line of the Head, it indicates grave misfortune or violent death, by which the ancients probably meant to infer that when the heart and the head are dominated by merely vital instincts, the life is menaced by misfortune, but, when the Line of Life is *very far* from the Line of Head, it indicates a life that accomplishes its course without much intelligence; so also if the Line of Life is very far from the Line of Heart, it indicates a life without love.

When the Line of Life is bi-forked at its termination, near the wrist, it means a total change in the way of life towards its close and, should one of the branches tend towards the Mount of the Moon, it indicates madness towards the end of existence. A double Line of Life is sometimes, but rarely, seen: this indicates excess of health and long life and also success in a military career. This line is sometimes called the Line of Mars. To a woman it indicates success in love. Three stars inside the line, but so close to it as to be almost on it, show that the subject will be much loved of men or women as the sex will determine, but that these signs will bring distress.

A circle on the Line of Life shows loss of an eye or disease of the eye at the period at which it appears on the line. If two circles appear the person will become blind. If the Line of Life terminates with many small lines it means slight illnesses towards the close of life.

A woman having two crosses on the upper part of the Line of Life is sensuous and immodest. A line going from the Line of Life and terminating with an island on the Mount of Jupiter shows lung disease or pleurisy at the time where such line starts. If at the end of the Line of Life, towards the wrist, there is a small triangle, it denotes loquacity and falsehood; but with a good Line of Head and Heart, tact and eloquence.

When the Line of Life throws branches upwards towards the Plain of Mars it means that, after long struggles, riches and honours will be acquired in old age. A line upwards from the Line of Life to the Mount of Jupiter shows success by the subject's own merits. This often makes its appearance quite suddenly.

A black spot on the Line of Life indicates an illness or some misfortune which affects the health. Lines going from the base of the thumb across the Mount of Venus and cutting the Line of Life denote illness from money worries if they stop at the Line of Head; and from heart troubles if they go direct to the Line of Heart. A line going from the Line of Life straight to the Mount of Saturn indicates accident from a four-footed beast. A line going from the Mount of Venus to the Line of Heart and terminating with a fork shows separation after marriage.[17] When this is seen, in conjunction with an island on the line of Fate, it has a worse indication—that of adultery and divorce. *One* deep line going from the joint of the thumb across the Mount of Venus and just cutting the Line of Life indicates a deep heart sorrow from the death or faithlessness of someone much loved.

CHAPTER XVIII.

THE LINE OF HEART AND LINE OF HEAD

The Line of Heart is placed immediately beneath the mounts at the root of each finger. This line, when clear, straight and well coloured, rising in the Mount of Jupiter and extending to the outer edge of the hand, signifies that its possessor has a good heart capable of strong affection. If, instead of commencing on the Mount of Jupiter, it does not take its rise till the Mount of Saturn, then the love will, in that nature, be rather of a sensual character. The Line of Heart sometimes stretches across the whole of the hand;

such a line announces a too great amount of tenderness—a passionate and blind devotion in affection.

When the Line of Heart is broken in several places, it means inconstancy, both in love and friendship. Should the breaks be seen immediately beneath the Mount of Saturn, it indicates a tragic end to the love; if beneath the Mount of the Sun, by pride;[18] but if between the Mount of Saturn and the Mount of the Sun, the heart-break will be occasioned by folly; if between the Mounts of Apollo and Mercury, by cupidity—the desire to make a better marriage in a worldly point of view; if the break occurs immediately beneath the Mount of Mercury, the evil issue of the love will be from caprice.

When the Line of the Heart appears in the form of the links of a chain instead of in one clear line, it indicates inconstancy and indecision—a tendency towards a series of *amourettes* rather than to a high and serious affection. If it goes round to the percussion of the hand it indicates jealousy.

The Line of Heart of a deep red colour indicates a power of love ardent even to violence; but when, on the contrary, the Line of Heart is pale and wide, it is an indication of coldness of temperament.

When, at its starting-point, the Line of Heart is seen to turn round the base of the Mount of Jupiter somewhat in the form of a circle, it is what the ancient Chiromancists called "Solomon's Ring," and indicates an aptitude for the occult sciences. If the Line of Heart joins the Line of Life between the thumb and forefinger, it is a sign (if the mark is in *both* hands) of a violent death; if only in one, of a serious, but not fatal, illness connected with the heart.

Should the Line of Heart droop towards the Line of Head and touch it, it is a sign of coldness in the affections: the instincts of the heart are swayed by worldly considerations. Red punctures on the Line of Heart mean as many wounds in the

Zaid n. adwan

affections as there are spots. White spots, on the contrary, show the persons of the opposite sex who, at some time of the subject's life, have given him, or her, a strong love. Should the spot be at the beginning of the line, above the Mount of Venus, the person will have the appearance and qualities given by that planet; if under the Mount of Jupiter he would be a Jupiterian; if under Saturn he would have the appearance and character of a Saturnian; under the Sun of a Sun person; if under Mercury the appearance and character would be those of a Mercurian; if near the side of the hand, of Mars; and if quite at the percussion of the hand, the qualities and physical appearance given by the Moon would describe the person.

If, on starting, the Line of Heart is bi-forked and one branch of the fork rises towards the Mount of Jupiter, it indicates great happiness of a glorious nature; but if the other branch stops between the finger of Jupiter and that of Saturn, it is merely negative happiness—a life passed without great misfortunes. When a hand (but this is rare) is entirely without the Line of Heart it indicates an iron will, wickedness and cruelty, unless the Ring of Venus is deep and goes towards the Mount of Mercury, in which case it would supply the place of the Line of Heart.

The Line of the Head rises between the Line of Life and the Mount of Jupiter and, when it is long and clear, it denotes a sound judgment, good memory and masterly intellect; but it must not extend across the hand in a *straight line*, as that signifies a disposition to avarice, or at any rate of extreme economy, because unless corrected by a rich Line of Heart, it would indicate an excess of calculation in the character.

If the Line of Head is long, but droops towards the Mountain of the Moon, it signifies ideality in excess. Life and its numerous duties and cares will be considered from an artistic and unreal point of view, for the Mount of the Moon, it will be remembered, represents imagination in excess, romanticism and superstition; and if the Line of the

Head droops very low to the Mount of the Moon, it indicates more than superstition—it is then mysticism.

If, instead of drooping towards the Mount of the Moon, the Line of Head rises towards the mounts at its close, the intellect will partake of the qualities of that mount towards which it rises: thus, if it rises beneath the Mount of Mercury, the intellect will be employed successfully in affairs or on the stage; if towards the Sun, in art and literature.

The Line of the Head pale-coloured and wide indicates a want of intelligence; so also does a very short line, only extending half-way across the hand. This is often seen in persons of medium intellect.

The Line of the Head broken in two immediately under the Mount of Saturn means, where the sign is on both hands, death on the scaffold, or at least, a fatal wound on the head. When this sign appears in only one hand (no matter which), it indicates a probability of madness from an unfortunate passion, or a broken limb, or a blow, but not fatal, on the head. When it is broken under the Mount of the Sun it shows injury to the right arm or, in a very artistic hand, illness from over-strain of the mental powers.

If the Line of the Head is long, thin and not deeply marked, it shows infidelity and treachery. If, towards its close, it mounts suddenly to the Line of the Heart, it signifies early death.

When the Line of Head is cut by a number of small hair lines, it indicates continuous nervous headaches; a cross in the middle of the line is a sign of approaching death, or of a mortal wound.

When the Line of the Head is not joined to the Line of Life at its starting-point, it indicates self-confidence and impulsiveness, jealousy and that sort of untruth which springs from exaggeration of facts, from over-impressionability. With the planets of

Zaid H. Adwan

Mars and Jupiter in excess, the Line of Head separate from the Line of Life gives audacity and enthusiasm and, therefore, success.

If large, round, red spots are seen on the Line of Head, they indicate so many wounds on the head; whilst white spots on the Line of the Head indicate as many successes in literature as there are spots to be seen.

A star on the Line of Head means a wound on the head, or madness if the line droops much to the Mount of the Moon, and the star appears at its termination.

A sister (or double line) of Head is rarely seen; but if it appears it is a sure sign of fortune by inheritance.

CHAPTER XIX.

THE SATURNIAN LINE

When the Saturnian Line starts from the wrist, exactly below the finger of Saturn, and goes in a direct line to it, cutting through the mount, but stopping at the root of the finger, it is a sign of a life of extreme happiness. If the line goes toward the mount of Jupiter, this happiness is the result of a marriage bringing both riches and love. If the Saturnian Line stops short at the Line of Head, it is misfortune in affairs through a false calculation; or, taken in conjunction with a troubled Line of Life, it would mean a physical brain affection.

If the Saturnian Line is straight and well-coloured at its termination—that is, as it nears the finger of Saturn—it indicates happiness and success in old age, however troubled the life may have been before. If this line only starts from the Line of Head, it denotes poverty and stupidity.

zain.adwan

The age, on the Saturnian Line, is counted from the wrist upwards; from the wrist to the Line of Head chiromancists count thirty-five years,[19] from the Line of Head to the Line of Heart fifteen years; and from the Line of Heart to the root of the finger are the remaining years of Life.

If the Saturnian Line is broken and irregular, it means trouble and worry in life; and according to whether these breaks occur on the Line of Head or on the Line of Heart, so will the troubles be of the head or heart—troubles arising from affairs or from the affections. If the Line of Life be irregular, denoting uncertain health, these troubles may be physical evils to the heart or head.

Short Lines crossing the Saturnian show vexations in either the affairs or in love-matters. A downward branch from the Saturnian going towards the Moon shows sorrow from the death or treachery of a woman. This is the same whether it be on a man's or a woman's hand.

If the Saturnian Line is twisted in a sort of spiral at the starting-point, but yet the upper part of it goes in a clear, direct line to the Mount of Saturn, and cuts through it to the root of the finger without penetrating beyond, it indicates a troubled and anxious youth, followed by riches and good fortune in middle age. If the twisted line continues and crosses the Line of the Head and the Line of the Heart, the troubles will continue until old age, and the good fortune be only quite at the close of life. A triangle, or small island, at the commencement of the line, shows death of the father or mother in early childhood.

If the Mount of Saturn is much wrinkled, and the Saturnian Line cuts through it, and is of a deep-red colour, and mounts as high as the third joint of the finger of Saturn, it indicates a violent and disgraceful end—death on the gallows. Upward lines from the Saturnian Line mean events of happy omen either in the affections or affairs at the age shown on the line; downward lines have the reverse signification.

There are some hands in which the Saturnian Line is very faintly indicated and, when this is the case, it signifies an uneventful, insignificant existence. The Esquimaux, for example, who live in a wretched climate, and live hard, unlovely lives, have absolutely, some of them, *no* Saturnian Line in their hands; and M. Serres, a famous French anthropologist, asserts that this line (which he calls the Caucasian Line) is only to be found in the hands of the white races; whilst M. Desbarrolles, another French writer on this subject, goes farther, and affirms that, among persons condemned to a dry, unintellectual vegetative life, even among the white races, the Saturnian Line is often found entirely wanting.

The Saturnian Line is one of great importance, for it corrects and modifies the significations both of the lines and of the mounts.

A double Saturnian Line, which is sometimes, but very rarely, seen, indicates great moral corruption and physical infirmities, brought about by abuse of material pleasures. A cross upon the line shows a change of position or a crisis in the affections at the age indicated by its position on the line. A star on the line shows disaster at the date at which it appears.

Downward lines from the Line of Heart towards the Fate Line show heart sorrows at the period when they cross the line. Widowhood is indicated in this way if the Line of Fate breaks and shows a total change in the way of life immediately afterwards. It sometimes only means a death at the period when it crosses the Fate Line.

CHAPTER XX.

THE LINE OF THE SUN AND LINE OF HEALTH

Zaid n. adwan

The Line of the Sun takes its rise either in the Line of Life or from the Mount of the Moon, and, ascending, it traces a furrow in the Mount of the Sun, but stops at the root of the finger; it signifies, when straight and well defined, and taking the course we have described, celebrity in literature or art, whether in poetry, painting, sculpture, or music. The mounts decide in some measure which branch of art is preferred. With Venus large it would probably be music or painting; with the Moon much developed, poetry—or at any rate literature of an elevated kind. Those having the Line of Sun thus traced, even who are not artists by profession and whom destiny has placed in quite inartistic careers, will always have artistic tastes, eye for colour, ear for music, or a perception of beauty in form or in language. Where the line only begins in the Line of Heart the artistic feeling is only appreciative, not productive, but when it rises as low as the Mount of the Moon, it signifies *creative* power.

If the Line of the Sun subdivides, in traversing the Mount of the Sun, into several lines, it indicates a tendency to cultivate several branches of art, which prevents the success which generally crowns excess of artistic feeling when confined in its expression to one especial art; it also indicates too great a struggle after effect in art; it is more significative of the dilettante, or patron of art generally, than the artist *pur et simple*. When the Line of the Sun, in its upward course, is barred by several transverse lines, there are obstacles in the career of art; but if the line continues and marks a single deep furrow in the mount till it reaches the root of the finger, these obstacles will, in the end, be conquered and success, riches, honours and celebrity will be attained. In a hand where the Sun Line begins above the Head Line, the deep line at its close only means riches after fifty, and has nothing to do with art.

The Line of Health, or, as it is sometimes called, the Line of the Liver, takes its rise at the wrist, near the Line of Life, and mounts in the direction of the Mount of Mercury. If it is well coloured and the line is not broken, it denotes good health, great power of memory and success in business pursuits; if the line becomes broken, or is forked at its

zain.adwan

close, before it reaches the mount, it indicates severe illness in old age. If this line starts from the Line of Life it is a sure sign of weakness of the heart's action. If the line is unequally coloured and gets redder as it crosses the Line of Head, it indicates a predisposition to apoplexy; if it stops suddenly on the Line of the Heart, a serious physical heart affection is likely.

The Line of Health sometimes takes a curved form on *one* hand, forming a sort of half-circle, from the Mount of the Moon to the Mount of Mercury. In this case it is called the Line of Presentiment and indicates vivid intuition, especially if Mercury is strong in his influence. When the Line of Health on *both* hands takes this form, it indicates mediumistic powers and powerful second sight. Should there be a long island at the starting-point, that is, near the Mount of the Moon in the Line of Presentiment, it indicates somnambulism.

When the Line of Health forms a large and distinct cross with the Line of Head, it shows a disposition for the study of occult science, but this is not the mystical cross which will be described farther on. An island on this line shows some internal illness at the date on which it appears on the line—that is, if before it reaches the Head Line, it would be *before* thirty-five; if after and between the Lines of Head and Heart, it would be between thirty-five and fifty; if later, during the remainder years of life. A twisted Liver Line is a sign of biliousness and indigestion; if it is of a red colour (as it frequently is where Mars is one of the ruling planets) it shows a tendency to feverish complaints.

The Line of Health is sometimes, but rarely, accompanied by another line called the Milky Way; when this line commences side by side with the Line of Health and mounts with it in an unbroken line, towards the finger of Mercury, it signifies a long life of uninterrupted happiness. This line, which is sometimes called the Via Lasciva, gives ardour in love, because a super-abundance of health gives force to passion.

CHAPTER XXI.

ON THE RING OF VENUS, THE WRIST LINES AND THE LETTER M TO BE SEEN IN MOST HANDS

The Ring of Venus seems to enclose, as in an island, the Mounts of Saturn and the Sun; this line is not seen in many hands and, when fully developed, signifies unbridled passion and debauchery of all kinds when, in conjunction with it, the Mount of Venus is strongly developed and marked with crossway lines.

If, with the signs mentioned above, the Ring of Venus is strongly marked, yet *broken* at its centre in *both* hands, it is a sign of eccentric and depraved passion; still, there are always modifications of these bad signs, and a very good Line of Head would, by bringing reason to bear upon passion, considerably mitigate the evil indications of the broken ring.

When the Ring of Venus is seen on a hand where both the planets Venus and the Moon are strongly indicated and where it is traversed by innumerable fine lines, it is a true sign of an hysterical temperament.

Sometimes the Ring of Venus will be seen to ascend and lose itself on the Mount of Mercury, leaving one end of the semicircle open, which mitigates, in some sort, the terribly strong instincts of voluptuousness indicated by this mark; but if, on the contrary, the semicircle, after extending itself to the Mount of Mercury, closes itself at the root of the finger, such a mark in the hand would indicate a terrible and absorbing power of passion, which would not hesitate at any means to secure its end.

A line traced on the wrist is a sign of long life and, if there are three of these lines, as is sometimes seen, it forms the triple bracelet. These lines indicate, in Chiromancy, thirty years of life each and the three lines form what is called the magic bracelet, indicating long life, health and riches. If these lines are formed irregularly, like the links of a chain,

and more especially if the first one—that next the hand—is so formed, it indicates a long life of labour, but acquiring ease and competency at its close. If a cross appears in the centre of the wrist, it indicates a rich heritage at the close of life.

When lines start upwards from the bracelet, and ascend towards the Mount of the Moon, they denote as many travels by land as there are lines. If a line starts from the wrist and, after traversing the Plain of Mars, goes to the Mount of the Sun, such a line presages riches and honours coming from royalty.

When these travel lines go as high as the Line of Head and Heart, they denote journeys during which some person is met who influences either the fortunes or the affections, according to whether the line stops at the Line of Head or Heart.

Lines lengthways on the Mount of the Moon mean sea-voyages; if these lines terminate with a star, it denotes shipwreck; if on both hands, death by drowning.

The letter M, formed more or less regularly in every hand by the Line of Life, the Line of Head and the Line of Heart, represents the three worlds—the material, the natural and the divine.

The first, the Line of Life, surrounds Love and Generation, as represented by the thumb, which is, as we have seen, sacred to Venus—the material world, or world of sense—but the Mount of Venus may either degenerate love to vice, or perfectionate it to tenderness. With high instincts the Mount of Venus is a good quality, since, *without it*, all the other passions are hard and selfish.

The second line—the Line of the Head—stretches across the natural world; it traverses the Plain and the Mount of Mars, which represent the struggle of Love and Reason in existence—the natural world, life as it presents itself to most persons. There is in the hand the Plain of Mars and the Mount of Mars; both mean a struggle: the Mount is the

struggle of resistance; the Plain of Mars (which is between the Lines of Head and Heart) is the struggle of aggression.

The third line, that of the Heart, encloses the divine world, for it surrounds the mounts which represent Religion, Jupiter; Fate, Saturn; Art, the Sun; Science, Mercury; all of which are especially influenced by the astral light, or fluid, emanating from the planets.

According to the proportions—the relative proportions—which these three lines bear to one another, so the life is influenced by the three different worlds represented. Thus we have a hand in which material (sensual) pleasure dominates: the line of the material world enclosing a space greatly superior to that of the two others. It is needless to give further examples of these differences, for, after all, this matter is but a *résumé* of what has been said before about the power of correction which one line has over the others. Given a wide range to sensual pleasure in the hand, but a good and extensive Line of the Head, the former will be corrected by it, as reason dominates passion; or given the strong powers of sensuality, with a wide range to the divine world by the space occupied between the Line of Heart and the mounts, and again, religion, love of art and science, will correct and keep under extreme sensuality. In reading the hand, each line must be judged with reference to the others, and the hand must be considered in all its bearings, before an opinion on the tendencies it indicates can be arrived at with any degree of correctness.

To face Chapter XXII.

CHAPTER XXII.

CONCERNING CHANCE LINES; THAT IS, LINES WHICH ARE SOMETIMES—BUT ONLY RARELY—SEEN ON ANY HAND

When two lines, starting from the Mount of Venus, join with a star on the Plain of Mars (see Plate 3, Fig. 1) it indicates two loves carried on at once and both having a disastrous issue.

A square with spots at all four corners placed on the Mount of the Sun (see Fig. 2) shows danger by fire with preservation.

A line from the Mount of Mars going to the Mount of the Sun (see Fig. 3) indicates love of glory, desire to attain distinction in life. A person with this mark in his hand would be stimulated rather than intimidated by a large audience, and would have great success in addressing multitudes. This line is good for soldiers, orators and actors, as it shows force, energy and moral as well as physical courage.

The figure of the sign Aquarius when seen on the Mount of the Moon (see Fig. 4) is a certain sign of death by drowning, *even when marked on one hand only*.

A circle on the Heart Line beneath the finger of Mercury (see Fig. 5) denotes the person as likely to cause—though unwittingly—the death of someone much loved.

A star on the Mount of Venus, low down on the Mount (see Fig. 6), indicates a man or woman who shall fall into dishonour by reason of sensual indulgence or unnatural vice.

A line starting from the Wrist Line, crossing the Mount of Venus and ending in a star on the palm of the hand (see Fig. 7), indicates that the person will lose some dearly-loved friend in a tragic manner.

The symbol of the planet Saturn, when seen in the palm of the hand (see Fig. 8), denotes the person to be malicious beyond expression, and likely to cause the death of someone by poison.

A line starting from the Head Line going through the Mount of Jupiter with a star (see Fig. 9), is an indication of a violent death before the age of thirty. Should the person be ruled by Venus, by poison; if under the Moon, by drowning; if under the Sun, by fire; if under Mars, by firearms; if under Jupiter, by horse accident; if under Mercury, by fits consequent on loss of money.

The Saturnian Line, crossed by transverse lines on the Mount of Saturn (see Fig. 10), indicates dangerous, but not fatal, wounds on the head.

zain. adwan

Many rings encircling the thumb (see Fig. 11) indicate an amorous and very inconstant disposition in either man or woman.

Two lines starting from the middle of the Mount of Venus and terminating in the form of an apex on the Mount of the Moon (see Fig. 12) indicate a great tendency to hysteria and to abnormal attachments; the latter is more especially indicated if Saturn and the Moon should be the ruling planets.

CHAPTER XXIII.

CONCERNING THE FINGERS AND THUMB AND NAILS

As the shapes and relative proportions of the fingers to the palm modify the indications given by the lines and mounts, it is necessary to consider them very attentively before giving a judgment in Chiromancy.

Fingers longer than the palm and with pointed tips show idealism; they are the expression of the Moon's influence when she is well-dignified at a birth. The Mount of the Moon in these hands would always be large. People with these fingers see everything in the golden light of imagination and find happiness in dreams of intangible beauty; poetical expression (ethereal, not passionate) is their natural language. They always incline to the marvellous—the sublime, the spiritualistic side of all things. Theirs the belief in omens, in occult literature, in the supernatural. Without, perhaps attaching themselves to any fixed creed, they are, by nature, worshippers; and the mysterious moan of the sea, the song of the brook, the roar of the torrent, and the sighing of the wind, are to them but so many revelations of the Deity. They are loyal to old associations and are never in advance of their age. They are easily moved to tears and are graceful in all their gestures. They can, in exalted moments, do without the necessaries of life and yet, from their intuitive worship of the beautiful, they are lovers

of the luxurious superfluities which make up an elegant and refined existence. People with these fingers do not age much; their hearts are eternally young, for they live a life of perpetual illusion and though often, alas! necessarily disappointed in both men and things, they never entirely lose faith in the poetry of existence.

Fingers the same length as the palm, and with slightly pointed tips, show refinement, correct taste and love of art—these are the fingers of those born under the dominant influence of the Sun.

Fingers the same length as the palm, but fleshy at their base and square at the tips, show practicality, family affection, love of animals, good judgment, respect for the world's opinion and much appreciation of material comfort. These fingers show the strong influence of Jupiter.

Long fingers, knotty at the joints and with square tips, show reasoning power and taste for science. Persons with these fingers are always in harmony with progress and have little or no veneration and are, therefore, never stirred by associations; with the antiquity of Catholicism, its mystical and somewhat sensuous worship, its celibate priesthood and golden aureole of saints and martyrs, persons having these fingers have no sympathy. If they belong to any fixed creed (and their logical powers are rather against this) they prefer Protestantism—or its offshoot, Dissent—where their real deity, Reason, is permitted full sway. These people love—with all the force of their nature—the study of history, jurisprudence, mathematics and the exact sciences. They are naturally clever at calculation and have much sense of order. Such fingers show the influence of Saturn, but not when most dignified; Saturn when most exalted gives mysticism, but then the fingers are not knotted at the joints and the tips are always spatulated.

Zain.adwan

Fingers that are shorter than the palm and with spatulated tips, show sensuality in love and materialism in all things, energy, love of field sports and indomitable courage. Such fingers indicate the influence of Mars at birth.

Fingers shorter than the palm, but with very pointed tips and thick at the base, show self-indulgence and love of luxury. Persons with such fingers are very sensuous and are, therefore, ardent pursuers of material pleasures, but yet with a certain refinement of taste which prevents their becoming grossly sensual. Such fingers are often seen in the hands of singers of both sexes; they indicate the strong influence of Venus in the nativity.

Fingers that are slender and longer than the palm, but with spatulate tips, indicate versatility, wit and intuitive perception. Such fingers show the dominant influence of Mercury.

In the relative lengths of the three divisions of the fingers Chiromancy also recognises the indications of three separate influences—that of the soul, that of the mind, and that of the body. Fingers that have the first division (that containing the nail) long, show high aspirations and power of veneration—soul; fingers with the second division longer than the other two indicate intellectual force—mind; whilst fingers having the lowest division longest show a love of material pleasure: people having such fingers, unless there are other modifying indications in the hand, are slaves to the body.

The first joint of the thumb (that which is nearest the nail) represents *Will*; therefore, when this is short, such a form indicates want of will—a character very impressionable and therefore easily led; when this joint is long, it indicates great power of will and therefore force of character. The second joint represents logic, judgment and reason; therefore, where this joint is long these qualities exist in excess and, where it is short, they are wanting in both.

zain.adwan

The third joint (that which is outside the Mount of Venus) represents the power which love—more especially the love between the sexes—will have on the character. If long and thick it implies the existence of strong passion; if short and flat a cold disposition—no attraction towards the opposite sex.

Poets have frequently the first joint of the thumb short (because want of will gives the rein to impulse and impressionability), and whilst the second—the intellectual one—is fairly long, the third is almost always large, full and long. This combination of impressionability, intellectuality and warmth of passion gives us the poets full of "the sweet, sad music of humanity."

These various types of finger-tips are often seen in the same hand, which shows that several planets have much the same amount of influence, in which case the following indications should be considered: The finger of Jupiter pointed gives idealistic religion and sense of honour; square, it would show reasoning power; spatulate, energy and impulse.

The finger of Saturn is rarely pointed, but when it is so, it rather mitigates the melancholy given by the planet and shows callousness and (if Mercury is strong in the hand) frivolity. Square tipped, it indicates prudence, love of agriculture and mechanical genius; spatulate, which is the ordinary termination of this finger, it betokens sadness and superstition, and, when the finger is abnormally long, a tendency to suicide; especially where, with it, there is a small weak thumb.

The third finger—that of the Sun—pointed shows idealism and artistic tastes; when square-tipped, realism in art and a love of wealth; spatulate, it gives spirit of adventure, especially when it is as long as the first finger; when the third finger is *longer* than the first and spatulate it indicates love of gambling and of speculation.

The fourth finger—that of Mercury—pointed shows occultism, intuitive perception, eloquence and talent for languages; square at the tip it denotes logic, facility of

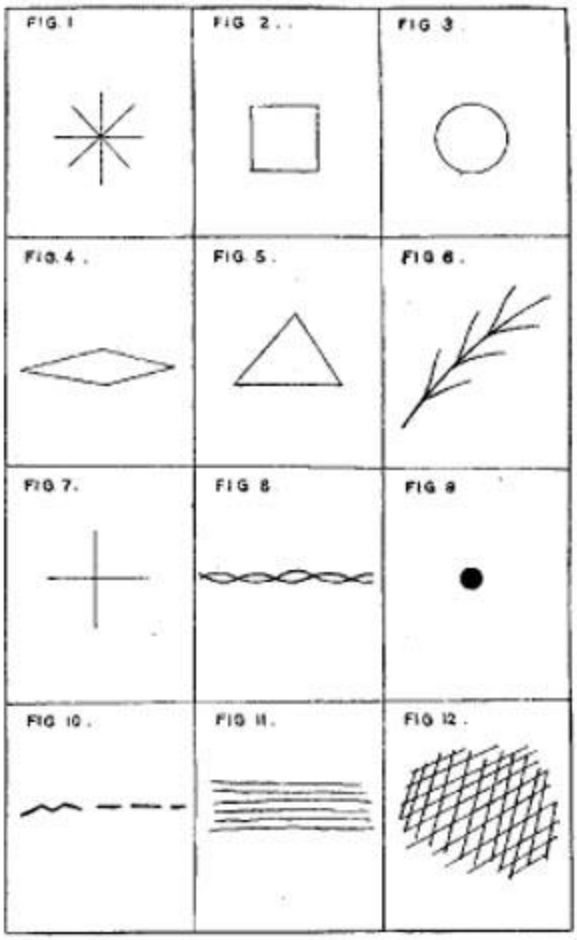
expression, science and love of research; spatulate, it gives movement, vivacity and, where the rest of the hand is bad, knavery in business and theft; a very short little finger shows unselfishness and, some old writers say, happiness in marriage.

A pointed thumb gives impressionability; square at its tip, decided but not obstinate will; the thumb bending outward shows generosity and impulse and, when much bent inwards towards the palm of the hand, avarice and reticence. People with short fingers are quicker, more impulsive and have more intuition than those who possess long fingers. Those with long fingers have much love of detail—often to a worrying extent; they are inquisitive and somewhat distrustful.

As regards the nails, short strong nails show courage, combativeness and critical faculties. White polished and filbert-shaped nails indicate sensitiveness and refinement, but no force of character. Short, weak, crooked and black-coloured nails show deceit and slothfulness. Round nails indicate a luxurious, pleasure-loving nature. Very thin nails—especially when the tips are bent inwardly—show delicacy of constitution. Red nails with little white marks on them indicate a choleric and cruel nature.

Those who have on the root of the thumb—that is, on the Mount of Venus—many crossbar lines are sensual and prone to gross indulgence in licentiousness. They who have these marks on their hands will have in their nativity—Venus in the 6th or 8th house (which houses rule the lower parts of the body), thus showing the entire concordance of Chiromancy with Astrology.

zain.adwan



To face Chapter XXIV.

CHAPTER XXIV.

OF THE VARIOUS MARKS TO BE SEEN ON THE HAND

Besides the Lines and Mounts already described there are other signs or marks which, as they modify the qualities given by the lines and mounts, should be carefully considered in giving judgment on the hand as a whole.

A star (Fig. 1) indicates something beyond our own power of action—a fatality for good or evil over which we have, personally, no power. A star on the Mount of Jupiter

indicates honours and distinction in marriage and great and unexpected glory, for Jupiter is always a favourable planet.

A star on the Mount of Saturn means assassination or death on the scaffold; or, in an otherwise good hand, death by paralysis.

A star on the Mount of the Sun (with no Line of the Sun) indicates fatal riches, which bring of themselves unhappiness in the affections. Should the Sun line be strong it would signify success in art, or military glory in a hand where Mars is strong.

A star on the Mount of Mercury shows theft and dishonour; on the Mount of Mars, death in battle; but a star on the plain of Mars, military glory.

A star on the Mount of the Moon, when on a voyage line, means death by drowning; when not on a voyage line, an illness connected with water, such as dropsy or diabetes.

A star in the centre of the hand shows that some person of the opposite sex will influence the life in an unhappy manner.

A star on the Mount of Venus means unhappiness caused by love.

Two stars on the top joint of the middle finger indicate death on the scaffold.

A square (Fig. 2) shows power and energy of the qualities of the mount on which it appears, except on the Mount of Venus, when it means imprisonment. A square announces preservation from accident when seen near any indication of such accident.

A circle (Fig. 3) on any of the mounts, but above all on the Mount of the Sun, signifies success in the qualities given by the mount on which it appears; but a circle on the lines of the hand has always a bad signification. A circle on the Line of Life means loss of one eye, and two circles would indicate total blindness.

An island (Fig. 4) is again always a bad sign; on the Line of Heart, it signifies adultery; on the Line of Life, illness, corresponding in time to its position on the line; on the Line

Zaid H. adwan

of Head, it would mean ruin arising from false speculations, or if illness is shown on the Life Line, it might indicate brain illness or neuralgia; on the Line of Health, disorders of the liver and the digestion; on the Saturnian Line, an island indicates happiness from an adulterous liaison; but if the island is broken in shape, it indicates poignant grief arising from an illicit affection. The duration of these affections is shown by the size of the island. An island at the commencement of the Saturnian Line indicates an event of an unfortunate nature, probably death of father or mother, in childhood or very early youth. The lines which go lengthways round the side of the hand, between the Line of Heart and the root of the finger of Mercury, show the serious attachments. A horizontal line barring these, or a black spot, shows widowhood. If the lines take the form of islands, it shows love for cousins or near relatives.

A triangle (Fig. 5) announces aptitudes of a favourable signification. On Jupiter it shows diplomatic distinction; on Saturn, mystical ability; on the Sun, success in art or literature; on Mars, military glory; on Venus, happiness in love; on Mercury, distinction in law, physics, or mathematics; but on the Mount of the Moon it indicates danger from the water.

A branch (Fig. 6) shows aptitude in the qualities of the mount on which it appears.

Chains (Fig. 8) always show obstacles and worries in connection with the qualities of the mount on which they appear.

A spot (Fig. 9) is sometimes favourable and sometimes the reverse. Red spots on the Line of Heart mean physical suffering from that organ. White spots show love conquests, and the lover is indicated by the mount under which these spots appear by the physical description of the planet to which the mount belongs.

Curved lines (Fig. 10) mean disaster wherever they appear. On the Line of Head, madness, especially should the line droop to the Mount of the Moon.

Zaid H. Adwan

Hair-lines (Fig. 11) show an excess of the quality of the line on which they appear.

Cross-bars (Fig. 12) are always obstacles, and show excess in the qualities of the mounts on which they appear; on the Moon, morbid imagination; on Venus, lasciviousness.

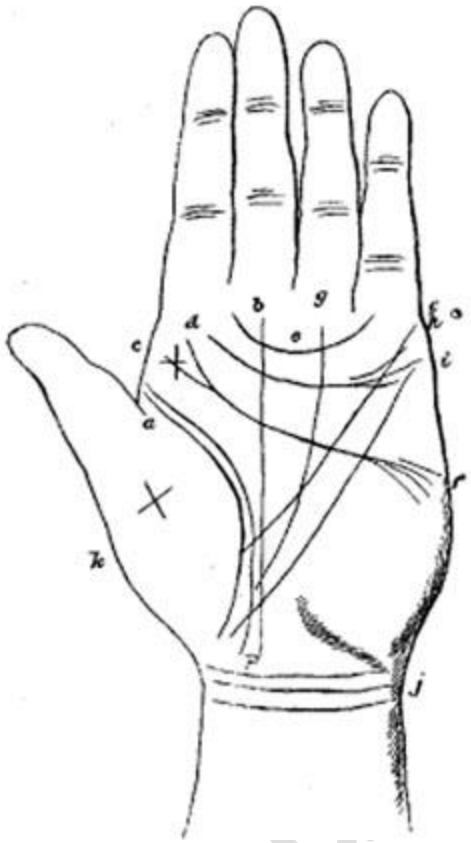
Two lines going from the Mount of Venus to that of Mars denote the pursuit of two love affairs at the same time, and a star joined to these lines shows that the matter has ended or will end in disaster.

A long island, extending from the Mount of Venus to that of Saturn, shows, on a woman's hand, seduction at the age when the sign crosses the Line of Life. Should a square appear on the line, she escapes the temptation.

A Line extending from a star on the Mount of Venus, and terminating with a fork on the Mount of Saturn, shows an unhappy marriage.

A Line going from a star on the Mount of Venus straight to the Mount of the Sun, foretells a great inheritance from the death of a near relation.

zaid n. adwan



THE HAPPY HAND.

To face Chapter XXV.

CHAPTER XXV.

THE TRIANGLE, THE QUADRANGLE, AND THE HAPPY HAND

The Triangle is the name given to the space enclosed between the Line of Life, the Line of Head and the Line of Health. If the angle is an equal one and the lines well coloured, it signifies a good disposition both as regards mind and body and also much health, courage, good reputation and a long and happy life. When the angles of the Triangle are not well defined, it signifies a dull and mean person, who will not rise above mediocrity. When the Triangle is wide as well as clearly defined, it indicates liberality

and nobility of mind. When it is narrow, it signifies avarice, cowardice and poverty. If the Triangle is altogether wanting in a hand, it portends much evil, a short life and much illness. A cross in the Triangle shows a quarrelsome disposition.

The Quadrangle is the square space contained between the Lines of Heart and Head. When broad it signifies a liberal, courageous person with much sense of honour, who will attain to the highest dignities in his profession and position in life.

Those who have the Quadrangle narrow are covetous and deceitful, and therefore untrustworthy in all business relations. A star in the middle of the Quadrangle shows honours and dignities, and a line from the Mount of Mercury running down to the centre of the Quadrangle indicates the friendship of great men, and much honour and distinction from these friendships.

In the plate at the beginning of this chapter we have a sketch of what is called "The Happy Hand," which is given as showing what are the happiest prognostications to be shown on the hand. An explanation of the lines and marks of this is given below.

The explanation of the Happy Hand.

Double Line of Life, which means good health and long life. The Saturnian Line straight and well-defined till it reaches its termination on the Mount of Saturn, which shows happiness in domestic life and good fortune to the end of life. Branches at beginning and end of the Heart Line, power of passionate tenderness. Cross on Mount of Jupiter, love and marriage. Ring of Venus, power of passionate attachment and much force of sympathy. The Line of Head long with branches to the Mount of the Moon, intellectual gifts and vivid imagination. Direct Line of the Sun, success in art and celebrity. Union of Venus with Mercury, love and good fortune in connection with the affections. Line of Health strong shows a vigorous constitution. Triple branches on the wrist, superabundance of vitality and long life.

Zaid n. adwan

A Cross on the Mount of Venus. This, taken in conjunction with the cross on the Mount of Jupiter, shows happiness in married life.

Of course it is seldom that such a conjunction of good lines is seen on the same hand; but still, in those born under a fortunate conjunction of the stars, many of these lines are seen together; but such hands are rare, for anxiety, grief and disappointment are the general rule and happiness the exception in this world.

Part III.

PHYSIOGNOMY

"La fisonomia è lo specchio dell' anima."—FINETTA.

CHAPTER XXVI.

PHYSIOGNOMY

"The face is the mirror of the soul," says Finetta, a mediæval Italian writer on the subject of physiognomy; and, to those who take the trouble to study the matter, the intelligence, the sentiments and the instincts of a person are all clearly manifested by the form of the head and features and their relative proportions, by the colouring of the skin, eyes and hair, by the fugitive expressions which, to an attentive observer, are seen to pass over even the most impassable faces, and "last, but certainly not least," by the lines left by the habitual passage of the expression of strong feeling, which, to the physiognomist, are visible even when the face is in repose.

Zaid n. adwan

We are in the habit of applying the term physiognomy to the *face* only, but the word has really a much wider signification. All things animate and inanimate have their physiognomy and, when judging of the character by the form of the features of the face, it would be impossible to ignore that given by the shape of the head, for, without altogether believing that the brain is mapped out in the manner described by phrenologists, there is no doubt that a good development of the front of the head shows intelligence, whilst a head which is inordinately protuberant at the back indicates the dominance of animal instincts in the organisation. If the back of the head is quite flat, it indicates coldness—want of passion in the nature. A head which is large just above the ears shows a tendency to anger and if the signs of benevolence on the brow and lips are entirely wanting it would mean cruelty; but in physiognomy the signs on both the head and face must be considered as a *whole*, and the qualities shown by *both* must be weighed one against another, before any right judgment can be arrived at. In this study, as in that of graphology and chiromancy, a deductive power of mind is required. Among twenty persons who may be sufficiently interested in physiognomy to study it, there will be scarcely more than one who will become a good physiognomist. One among the countless objections which have been urged against physiognomy is that many physiognomists make erroneous judgments; but, granted that they do so, it is their want of discernment, or more probably their want of deductivity—not the science—which fails.

There is a certain sort of *instinctive* power of judging character by the face, possessed by children and animals, which is in harmony with the theories of those who have thought and written most upon this interesting subject.

We are all of us—women, perhaps, more than men—daily influenced by this sort of *instinctive* physiognomy: for there are few people who do not, when they first see a stranger, form a judgment of him, in which they are, of course, only swayed by his outward appearance, although they may never have even heard the word physiognomy.

The *temperament* has an immense amount of influence over the character and this temperament is shown more especially by the colour and texture of the skin and hair. It is temperament which precipitates, or retards, the effects of illness and age and temperament is the result of the astral influence which presided at our birth.

These temperaments have been classified under four heads—viz., the sanguine or choleric, the lymphatic, the bilious and the melancholic.

The first, the sanguine or choleric, is the result of the astral influence of Mars and Jupiter; the lymphatic, of the Moon and Venus, but more especially the Moon; the bilious (which is especially the intellectual temperament) of the Sun and Mercury and the melancholic temperament is the result of the dominance of the sad planet, Saturn. The sanguine temperament is shown by a skin with a good deal of colour in it, either of a soft pinky white with a rosy peach-like colour on the cheeks, in which case it is Jupiter which dominates in the temperament, or of a deep red colour all over the face, when the sanguine temperament is dominated by Mars, the hair being red or brown, crispy or curling.

The lymphatic temperament is shown by a soft, pale skin of a thick dead white, the lips and cheeks being only slightly coloured; the hair is fine and long, but not thick, and is light, not golden, but rather colourless, or what the French call "*un blond cendré*"—that is, of an ash-coloured fairness, sometimes of a soft brown, when Venus is the dominating planet. The bilious temperament is the result of the combination of the astral influences of the Sun and Mercury, the planets which give artistic feeling and intelligence.

Those having this temperament have yellow skins of a soft, fine texture and when the Sun is the dominant planet they have a vivid colour in the cheeks; the hair of those of the bilious temperament is golden and is generally curly or wavy; if the melancholic temperament given by Saturn is in combination (and it is frequently so in the bilious

temperament) with the yellow-tinted skin of the bilious temperament, we find also the straight, deep black hair peculiar to the Saturnian.

The melancholic temperament is that of those born under the dominant influence of Saturn. People of this temperament are of a pale or livid, and, sometimes, of a greenish-tinted or earth-coloured skin and their hair is always of a dead black. It must be remembered that though one planet may dominate at a birth, there are always present others which have also their influences, though in a secondary degree, so no person is of *one* temperament without any admixture of the others, although one may and often does dominate the others.

Thus no one is *exclusively* sanguine, bilious, lymphatic, or melancholic. One person could be at once bilious, melancholic and lymphatic. We sometimes see the apparently contradictory temperaments of the melancholic and sanguine in the same person, but, generally speaking, one temperament dominates, modified by one or more of the others. This makes one of the sources of the variety of character we see in those about us, no one person having precisely the same modification of temperament, to say nothing of the difference of intellectual gifts. Now, as the temperament produces the character and the character the passions, it is very necessary, in order to be a good physiognomist that we should be thoroughly expert in being able to assign to each person under judgment the exact amount of domination of each of these four temperaments and this is only to be done by noting the colour and texture of the skin and hair. Aristotle has said that though there is a certain physiognomy of the whole person, the principal signs to guide us in a knowledge of human beings are to be found on the face; and this is perhaps because the skin of the face is somewhat differently constituted to that over the other parts of the body. It is more transparent than that of the other parts of the body, and thus more readily reflects the different colours—the vivid flush of joy, the blush of shame, the livid hue of envy, the pallor of fear, the different passions by which we are agitated. The face also is the seat of the eyes and the lips, both of which features (being

continually in movement) make the face, as the old Italian writer has said, "the mirror of the soul."

Even those who habitually deny the power given by a knowledge of the science of physiognomy admit that *in certain moments* they have been able to judge of what they could ask for from the expression they saw on the face of the person with whom they were dealing. Now, if this were so at one moment, why should it not be so always? When the soul is agitated, that agitation shows itself, at once, upon the face by the variation of its colours and by the contraction of certain muscles about the features. Both this changing of colour and this movement of the features vary according to the passions which produce the agitation and these different expressions most people can read at a glance. No one confounds the expression of happiness with unhappiness, of love with hatred, of hope with despair, of jealousy with trustfulness, of envy with sympathy. Habitual drunkards show their vice on their faces, even when they are perfectly sober; so also do the other vices show themselves by the lines left on the face by the constant recurrence of the contraction of the features when under the immediate and violent influence of the ruling passion. By dint of continually exercising the faculty of observation they come to see expressions and lines on the face which, though perhaps quite lost upon others, give them indications of character which are sometimes startling revelations. Here, again, is another objection which is often advanced against the study of physiognomy. Does it not, by laying bare the vices and weaknesses of human nature, induce a cynical opinion of human nature? No; for, whilst it makes us clear-sighted as to the vices, it also reveals to us many sweet and noble qualities in those by whom we are surrounded, which, perhaps, were never suspected by us. No one better understood his fellow-men, no one was ever more alive to "the sweet, sad music of humanity," than Shakespeare. His large-hearted, sympathetic nature gave him intuitive perception of character, and this, aided by his wonderful powers of observation, must have made him a physiognomist. He "looked quite through the thoughts of men," and yet, with all this

zain.adwan

wondrous knowledge of human nature, he says, "What a piece of work is a man! How noble in reason! How infinite in faculties! In form and moving how express and admirable! In action how like an angel! In apprehension how like a God!"

THE PLANETS' PLACES ON THE FACE FACSIMILE FROM AN OLD WOODCUT, DATE 1657

To face Chapter XXVII.

CHAPTER XXVII.

THE FOREHEAD AND EYEBROWS

"One part of the forehead," says a Chinese proverb, "shows our faculties, the other part the use we make of them." This is, in a great measure, true; for the form and height of the brow show the degree of thought and power of intellect, whilst the skin of the forehead, its colour, lines and tension, denote the passions and the state of mind. Though the skin of the forehead may be equally wrinkled in different faces, the forms which

these lines take vary very much. The first line next the hair, which is rarely seen till past middle age, is referred to the influence of Saturn; the second to Jupiter; the third to Mars; the fourth, over the right eyebrow, to the Sun; the fifth, over the left eyebrow, to the Moon; the sixth, between the eyebrows, to Venus, whilst Mercury is assigned his place on the bridge of the nose (see plate).

When the Line of Saturn is long and well-defined, it indicates the prudence and sagacity which ought to come with age; when it is broken or curved in an oblique manner it shows peevishness and avarice.

The Line of Jupiter, straight and clearly-defined, shows an honourable and just person; if broken or taking oblique curves it indicates a very voluptuous person.

If the Line of Mars should be long and clear, and stretching across the forehead in one continuous line, it denotes courage and much warlike ambition; if the line be broken, such a person will be a brawler and quarrelsome and will experience ill fortune in war.

The Line of the Sun being perfect and reaching nearly to the middle of the forehead, shows ambition, good judgment and success; being broken or oblique in its form, it shows egotism and love of money.

The Line of the Moon, clear and perfect above the left eyebrow, much imagination and also much travelling into strange places. When this line is broken or much curved, it indicates caprice and want of truth.

The Line of Venus, delicately marked and straight, shows tenderness and success in love matters; if broken and curved, the reverse.

If three lines appear in the place of Mercury across the bridge of the nose, they denote eloquence and wit; if more than three, loquacity and deceit.

Zain n. adwan

So much for the *lines* on the forehead. As to the *form*, Aristotle tells us that "a very large and prominent forehead shows stupidity"; it is quite true that men of the highest intelligence have foreheads of medium height, but exceptionally broad and full over the eyebrow.

A forehead which is very full over the eyebrows and rather low than high, shows intuitive faculty, artistic perception and idealism; we see this form of brow in all the antique statues of Apollo. A very projecting forehead, fuller above than below, and so large as to appear to dominate the whole face, is generally the forehead of a slow if not a dull intellect. A perpendicular forehead, well rounded at the temples, rather high than low and having straight, well-defined eyebrows, shows solid power of the understanding, love of study and power of concentrating the attention, but it is not the forehead of the poet, painter, or musician.

Arched foreheads, somewhat low, but full at the temples, with long, sweeping and mobile eyebrows, appear properly to be feminine, since they show sweetness and sensitiveness of nature.

High, narrow and wholly unwrinkled foreheads, over which the skin seems tightly drawn, are indicative of weakness of the will-power, want of imagination and very little susceptibility. They are the foreheads of narrow-minded, commonplace persons. Of course other features may soften these indications; intelligent eyes may give intellect, or a sweet and tender mouth feeling enough to, at any rate, diminish the unpleasant indications of this type of forehead.

Foreheads not altogether projecting, but having angular and knotty protuberances upon them, denote vigour of mind and harsh and oppressive activity and perseverance. To be in exact proportion, the forehead should be the same length as the nose. In Greek art, however, it is generally shorter, which gives softness and elegance to the face. It should be oval at the top, or somewhat square; if the latter, it gives more force—if the former,

zaid n. adwan

more sensibility of character. It should be smooth in repose, yet have the power of wrinkling when in deep thought, or when in grief or anger; for foreheads over which the skin is so tightly strained as never to change under these circumstances show a dull, unsensitive and unintellectual nature. A forehead should project more over the eyes than at the top, and there should be a small cavity in the centre, separating the brow into four divisions: but this should be so slightly accentuated as only to be seen when the forehead is in a strong light coming from above it.

When the eyebrows are far from each other at their starting-point between the eyes, they denote warmth, frankness and impulse—a generous and unsuspicious nature. A woman or man having such eyebrows would never be causelessly jealous. Eyebrows, on the contrary, which meet between the eyes in the manner so much admired by the Persians denote a temperament ardent in love, but jealous and suspicious: all Saturnians have these eyebrows.

Eyebrows somewhat higher at their starting-point, and which pass in a long sweeping line over the eyes, drooping slightly downwards at their termination, show artistic feeling and great sense of beauty in form. The Empress Eugénie's eyebrows are of this form, which gives a sweet and wistful expression to the face and which some old writers have asserted to be the sign of a violent death.

Eyebrows lying very close to the eyes, forming one direct, clear line on strongly-defined eyebones having the same form, show strength of will and extreme determination of character. This sort of eyebrow appears on the busts of Nero; but there its indications of determination are deepened with cruelty by the massive jaw and the development of the cheekbone by the ear. This form of eyebrow, in conjunction with other good indications, would mean only constancy in affection, power of carrying out a project despite all difficulties and taste for science.

Zaid Adwan

Eyebrows that are strongly marked at the commencement and then terminate abruptly without sweeping past the eyes, show an irascible, energetic and impatient nature.

Thick eyebrows, somewhat arched, show artistic perception of beauty in colour. Delicately marked eyebrows, slightly arched, indicate tenderness.

Eyebrows lighter than the hair show weakness and indecision. Eyebrows much darker than the hair denote an ardent, passionate and constant temperament.

Angular, strong and sharply interrupted eyebrows close to the eyes always show fire and productive activity. No profound thinker has weakly marked eyebrows, or eyebrows placed very high on the forehead. Want of eyebrow almost always indicates a want of mental and bodily force. The nearer the eyebrows are to the eyes, the more earnest, deep and firm the character; the more remote from the eyes, the more volatile and less resolute the nature.

Eyebrows the same colour as the hair show firmness, resolution and constancy; but in judging of the eyebrows it must be remembered that if form and colour give different indications, the *form* (as this also means that of the brow) gives the most important indication, the colour and texture of the eyebrow being secondary to its *position* as regards the eyes and forehead.

CHAPTER XXVIII.

THE EYES AND EYELASHES

The eye has been called "the window of the soul," and not without reason, for it seems more than any other organ to be capable of expressing all its emotions. The most tumultuous passions, the most delicate feelings, the most acute sensations, the eye expresses in all their force and in all their purity, as they arise and transmits them by

zaid n. adwan

variations so rapid as to give to the lookers-on the very image of that with which it is itself inspired; for the eye receives and reflects the intelligence of the thoughts as well as the warmth of the feelings.

The colours most common to the eyes are brown, grey, blue, hazel and black, or what we *call* black—for those eyes which appear to be black will generally be found to be of a deep yellowish-brown when looked at very narrowly; it is the distance only which makes them seem to be black, because the deep yellow-brown colour is in such strong contrast to the white of the eye that it appears black. There are also eyes of so bright a hazel as to seem almost yellow; lastly, there are eyes that are positively green. Very beautiful, too, are some of the eyes of this colour when they are shaded—as is very often the case—with long, dark eyelashes; but, though beautiful, they are not indicative of a *good* disposition.

Green eyes, although their praises are often sung in Spanish ballads, show deceit and coquetry. We sometimes see eyes which appear to be a combination of yellow, orange, and blue, the latter colour generally appearing in streaks over the whole surface of the iris, while the orange and yellow are set in flakes of unequal size around and at some distance apart; these eyes are indicative of originality, amounting, at times, to eccentricity. No commonplace person has this sort of eye; they show intellectuality, and, in most cases, literary ability.

There are eyes which are remarkable for being of, what might be said to be, no colour. The iris has only some shades of blue or pale grey, so feeble as to be almost white in some parts, and the shades of orange which intervene are so small that they can scarcely be distinguished from grey or white, notwithstanding the contrast of colours. The black of the pupil is, in these eyes, too marked, because the colour of the iris around it is not deep enough, so that in looking at them we seem to see only the pupil. These eyes are expressionless, for their glance is fixed and dead; they invariably belong to persons of

the lymphatic temperament, and they indicate a listless and feeble disposition, incapable of enterprise and a cold and indolently selfish nature.

Blue eyes are more significant of tenderness and of a yieldingness of purpose than either brown, black, or grey eyes. There are occasionally to be met strong characters with this tint of eye, but then they will be found to have other indications in the rest of their physiognomy which correct the delicacy and yieldingness of this coloured eye. Blue-eyed people are not inconstant, like those of the hazel and yellow eyes, but they yield from affection.

Angry, irritable persons have frequently eyes of a brownish tint, inclined to a greenish hue. Although the purely green eye of which I have spoken indicates deceit and coquetry, the propensity to greenish tints in the eyes is a sign of wisdom and courage. Very choleric persons, if they have blue eyes, have also certain tints of green in them and, when under the influence of anger, a sudden red light appears in them. Such eyes as these are generally found in connection with the sanguine, or, as it is sometimes called, choleric temperament; that is, in those persons who have been born under the double influence of Jupiter and Mars; but, when we see these red tints in the eyes, it would be a sign that, of the two planets presiding over this temperament, Mars was dominant.

Clear grey-blue eyes, with a calm steadfastness in their glance, are indicative of cheerfulness of disposition, of a serene temper and a constant nature. These eyes are peculiar to the Northern nations; one meets with them among the Swedes, and also sometimes amongst the Scotch. The blue eyes we see among the rare blondes of the South—that is, in Italy and Spain—always have eyes in which there are some greenish tints; and such eyes, though often called light blue, have none of the qualities of serenity and constancy which belong to the light blue eyes of the North. Neither must the pleasant light blue eye, with the honest glance, be confounded with another sort of eye

of a pale blue, almost steel-coloured hue, which has a continually shifting sort of motion both of the eyelids and the pupils of the eyes. People with such eyes as these are to be avoided, as they are indicative of a deceitful and selfish nature. Very dark blue eyes, with something of the tint of the violet, show great power of affection and purity of mind, but not much intellectuality.

Grey eyes, of a somewhat greenish grey, with orange as well as blue in them, and which are of ever-varying tints, like the sea, are those which denote most intellectuality. They are especially indicative of the impulsive, impressionable temperament—a mixture of the sanguine and the bilious—which produces the poetic and artistic natures. The line—

"The poet's eye, in a fine phrenzy rolling,"

does not suggest a blue, or even a black, so much as the changeful, ever-varying tinted, grey eye; and it is a fact that in England (where there are more varieties of tints in eyes than in any other country) the poets have almost always grey eyes. A biographer of Byron speaks of his "beautiful, changeful grey eyes, which deepened in colour when he was under the influence of tenderness and passion, and which glowed with a red light when he was angry." Shakespeare also had, we are told, grey eyes, and so had Sir Walter Scott; whilst Coleridge had eyes of a greenish grey. Among the artists, too, eyes of this colour abound.

Black eyes, or what are considered such, are indicative of passionate ardour in love. Brown eyes, when not of the yellowish tint, but pure russet brown, show an affectionate disposition; the darker the brown—that is, the more they verge on to that deepest tint of brown which is seen in eyes we are in the habit of calling black—the more ardent and passionate is the power of affection. The brown eyes which do not appear black—that is, which are not dark enough to appear so—are the eyes of sweet, gentle, and unselfish natures, without the inconstancy of the light brown or *yellow* eyes—"golden eyes," as they were called by a lady novelist—and which are very little more to be

trusted than the green eyes already spoken of. The maiden in Longfellow's *Hyperion*, of whom he says,

"She has two eyes so soft and brown,
She looketh up, she looketh down;
Beware, beware, she is fooling thee,"

must have had these *light* brown eyes.

Eyes which show no lines when in sorrow or laughter denote a passionless and unimpressionable nature. Eyes of a long almond shape, with thick-skinned eyelids which appear to cover half the pupil, are indicative of genius; if in conjunction the forehead is that which shows idealism, and has one deep perpendicular line between the eyebrows, which is indicative of originality of mind and which is generally to be seen in the forehead of distinguished writers and artists. It is very remarkable in all the portraits of Michael Angelo. The almond-shaped eye, however, even without this peculiar form of forehead, always means a susceptible, impressionable nature. Eyes which are large, open and very transparent and which sparkle with a rapid motion under well-defined eyelids, denote elegance in tastes, a somewhat susceptible temper and great interest in the opposite sex.

Eyes with weakly-marked eyebrows above them and with thinly-growing eyelashes which are completely without any upward curve, denote a feeble constitution and a melancholy disposition. These eyelashes are often seen in people who combine the lymphatic and melancholic temperaments—that is, in persons born under the combined influence of the two melancholy planets, Saturn and the Moon. The eyes of these people are either of a pale, colourless sort of blue, or of a dull black without any sparkle in them.

Want of eyelash, like want of eyebrows, shows a general want of force, both of body and intellect.

zaid n. adwan

Strong, dark and short eyelashes show force of character and a strong and obstinate will.

Eyes with sharply-defined angles, sinking at the corners, show subtlety of mind; the sharper the angle and the more it sinks, the greater the delicacy of perception it denotes; but when very much developed it shows also craftiness amounting to deceit. Well-opened eyes with smooth eyelids and a steady and somewhat fixed glance denote sincerity. Lines running along the eyelid from side to side and passing out upon the temples denote habitual laughter—a cheerful temperament, or, at any rate, one in which the sense of humour is strong.

We sometimes see (but it is rare) persons whose eyes are of different colours. For instance, one eye will be of a bluish-grey, whilst the other will be so flecked with orange or tawny yellow spots as to appear what might be called a brown eye. This peculiarity of having eyes of different colours is sometimes to be seen in dogs, and very often in cats of the Persian breed, or white cats, but it is very rare in human beings. An old Italian writer says that people having eyes of different colours are likely to become mad. Having, during the whole course of my life, only known two persons having this peculiarity, I do not feel qualified to pass an opinion as regards this indication. One of these persons certainly was mad on several points; and, when it is added that the other is the writer of this book, many of its readers may be inclined to think that the mediæval physiognomist's theory might very possibly be correct.

CHAPTER XXIX.

THE NOSE

We often see fine eyes in an otherwise ugly face, but rarely is a thoroughly beautiful nose found in a face which could be called ugly, for the nose is the keynote of the face, and in it lies the chief characteristic of the countenance. Beautiful eyes and beautiful

lips have, it is true, more charm—it is the expression of the eyes and lips of those we love which we most remember in absence—but it is the nose which, more than any other feature, most affects the general character of the face. This will be seen if we try the experiment of drawing the head and face of any beautiful statue—say the Venus of Milo, for instance—and, while giving it all its fair proportions of brow and cheek and chin, we substitute a small turn-up nose, or, worse still, a flat or snub nose, for the noble yet softly gracious line of the nose in this most perfect head and how much we should lower the noble type of beauty this Venus presents! Of course no one in real life could be unattractive with such a brow and beautifully shaped eyes, to say nothing of the perfect lips and softly rounded lines of the chin; but the nobility of the face would be entirely lost by this alteration of the lines of the nose; whilst we might alter the beautiful lines of the eyes, narrow the brow, and even take from the softly voluptuous contour of lips and chin, yet by leaving untouched the perfect form of the nose we should still retain the dignity of expression which is so characteristic of this statue.

A nose to be perfect should equal the length of the forehead; it may, when the forehead is exceptionally low, be even longer than the forehead (and in most of the beautiful antique statues it is so), but on no account should it be shorter than the brow. Viewed in front, the nose should be somewhat broader at its root—that is, where it starts from the brow—than below. The end of it should be neither hard nor fleshy, but it should be well defined, though neither very pointed nor very broad, for all extremes of forms in any of the features are bad. Viewed in profile, the distance from the line of the wing of the nose to its tip should only be one-third of the length of the nose. Thus, those noses which stand very much out from the face as they near the end of the nose, whilst they are low on the bridge and between the eyes, are out of proportion. Those having such noses are vivacious, but wanting in dignity and force of character. They are impressionable, inquisitive and inconstant.

The nostrils (from the different forms of which many indications are given) should be pointed above and rounded below. The sides of the nose at its root between the eyes should close well with the line of the eyebone (as one sees them invariably do in the antique statues), and should be at least half an inch in width. Perhaps a better rule of proportion—as regards the whole face—is that the width of the nose between the eyes should be exactly the length of the eye.

Noses which are arched from their starting-point between the eyes show capability of command, energy and force of character. It will be remembered that the Duke of Wellington—the Iron Duke—had this sort of nose. Of course, this form in excess (as it certainly was in his case), without the characteristics of self-control and other good points in the face, would not have the same indication. A very prominent nose, like the beak of a parrot, with a narrow brow and retreating chin, would give stupid obstinacy; but, in an otherwise good physiognomy, a prominent nose gives force, command and productive energy.

It cannot, however, be denied that one *sometimes* comes upon noses which are rather small in proportion to the rest of the face and which are so devoid of arch as to be almost concave in their line when seen in profile, in persons of fairly good understanding; but such noses belong rather to those who appreciate, than to those who produce, works of literature and art. The people having these noses, provided the brows show some intellectuality, will be found to enjoy the beautiful influences of works of the imagination, but they themselves possess little or no creative power.

Straight noses give indications between these two extremes; they may belong to persons of the creative, or simply appreciative, order of mind. The form of the head and brow and the line of the eyebrows would determine to which class they especially belong. Arched noses with broad backs denote force of character. Swift and Napoleon Bonaparte had noses of this type. This sort of nose, with an arch starting from the root,

is seen in almost all the busts of the Roman emperors; it is, in fact, frequently called the "Roman nose," and is very typical of the race which was for so many ages dominant in Europe; whilst the beautiful straight nose (which we are accustomed to call Grecian, because it is seen in almost all the antique statues) is quite as indicative of the perception of beauty in art and literature and of the subtlety of mind which distinguished the Greeks. The creative force in the antique straight nose is given by its *proportion* to the rest of the face, for it is always larger in proportion to the brow, cheeks and jaws than the strongly-arched broad-bridged nose which we call Roman, and thus it is indicative of quite as much productive force as the arched Roman nose, with infinitely more delicacy of perception; a small straight nose shorter than the forehead and set in a large round face, shows timidity and foolishness and is the nose of an unintelligent person.

High noses that are not broad-backed are often seen in the faces of men of letters, but a high *thin*-backed nose, which seems to start up in a sharp ridge when seen in profile, is more indicative of penetration and acuteness than force of mind. These noses have generally fine, sharp tips, with a downward curve; this is an indication of wit. Voltaire and Sterne had such noses; they are generally seen in combination with thin and flexible lips and a somewhat pointed chin. A nose which is bent downwards is also indicative of sadness of disposition, for it is one of the signatures of the melancholy planet Saturn; but wit may exist (in fact generally does so) with a somewhat sad temperament. Voltaire's wit is almost always cynical, and cynicism grows out of a want of hope, a want of belief in one's fellow-creatures; whilst in Sterne (the writer of the inimitable though now little-read work, *Tristram Shandy*) there is always, even in his brightest sallies, an under-current of pathetic sadness. People with this sort of nose are sarcastic, somewhat hypochondriacal and very often reserved and morose. If, with this form of nose, the nostrils are narrow and almost closed and the wings of the nose pinched, the indications are still more those given by the melancholy planet Saturn; the more elastic and freely moving the nostril with this form of nose, the more bright and the less

zain.adwan

sardonic the wit. A person with a broad Roman nose, having this violent downward curve over the mouth, is one to be avoided, for this combination denotes a secretly voluptuous temperament—a man or woman of strong passions hidden beneath a cold and reserved manner. Broad-backed fleshy noses, round and full at the tips, with intellectually good brows, show a genial temperament and a sense of humour. Without the good indications of the brow they would only show love of good cheer and a certain good-humoured carelessness.

Snub-noses—that is, noses short in proportion to the brow and with round fleshy tips—are indicative of commonplace, somewhat coarse natures, especially if the nostrils are round and the bridge of the nose very low between the eyes.

What is called a turned-up nose shows vivacity of temperament, jealousy, talkativeness, impudence (growing out of a certain amount of self-esteem) and petulance.

There is a sort of delicately turned-up nose which we often see in pretty women, and which, though it shows wilfulness and coquetry—things not uncommon in pretty women, since the song tells us—

"For oh! these charming women,
They all have wills of their own"—

is significant of delicate perceptions and a certain intuitive cleverness which is thoroughly feminine and, therefore, very attractive to men. These noses—which are especially the noses of charming women—are well raised at the root; in fact, have all the delicacy of line of a straight nose, except that the extreme tip has an upward curve. It must have been of one of these delicate and thoroughly feminine noses that Tennyson must have been thinking when he describes one of his heroines as having a nose—

"Tip-tilted like a flower."

Zaid H. adwan

Flexible nostrils, which quiver under excitement, show an ardent, poetic, and sensitive temperament.

Very open and flexible nostrils show ardour in love and if seen in conjunction with large, full and slowly-moving eyes and a full under lip, indicate a voluptuous and passionate nature.

Closed nostrils show melancholy, timidity and absence of hopefulness—a person who habitually sees everybody and everything *en noir*.

Round nostrils show animal instincts and a somewhat low type of individuality; they are generally seen in snub-noses, which of themselves give the same indication.

Noses which have on both sides many wrinkles, which become visible on the slightest motion and never entirely disappear, even in a state of complete rest, show cunning and sarcasm.

When the line (which, after extreme youth, is always more or less seen from the nose to the mouth) is very strongly marked, and descends at a great distance from the corners of the mouth to the chin, it evidences an anxious and melancholic nature.

CHAPTER XXX.

THE MOUTH, TEETH, JAW AND CHIN

A mouth to be beautiful should be in harmony as regards proportion with the rest of the features of the face; that is, it should be neither remarkably large nor remarkably small. Neither the upper nor the lower lip should project beyond the other when the mouth is closed. The lips should shut easily over the teeth, and in doing so should fall into a flowing line of curves without compression. The more the lips are endowed with motion

zaid n. adwan

and the more richly they are coloured, the finer and more delicate are the human passions they indicate.

An excess of even good form is bad; thus if the full rich lines of a generous mouth are exaggerated, we have the indication of sensuality, whilst the finer susceptibilities shown by delicately moulded lips may, by a little excess towards thinness, give fastidiousness and even avarice.

The middle-sized mouth, which combines strength with warmth of feeling, whilst it steers clear of coarseness, is what gives the best indications. Such a mouth shows courage, generosity, and affection.

A mild, somewhat overhanging upper lip generally signifies goodness, or rather kindliness of disposition; but if very much overhung it shows weakness of purpose and an irresolute, vacillating character and, where the under lip is small as well as retreating and the chin also small, it is an indication of imbecility.

A mouth in which the lower lip projects shows prudence amounting to distrust and melancholy. We often see this form of mouth with the down-drooping nose; both are indications of the dominating influence of Saturn at the birth of the person possessing such a combination of features. If the under lip should be very full as well as projecting and droops in a flaccid manner without closing over the teeth when the lips are in repose, it is a sign of a sensual nature. Of course an intellectual brow and a firm and energetic form of nose would lessen the evil of such an indication, but there is always a tendency towards the grosser pleasures of the senses in a person with such a form of lips.

A mouth with lips habitually apart denotes eloquence, if the rest of the face gives intellectual indications; but if none of the signs of mental power are there, it would only signify a chattering person wanting in decision and promptness of action.

Zain Adwan

A firmly closed mouth shows courage, fortitude and determination; even an habitually open mouth will be seen to close with a sort of forced compression when endurance is necessary. Everyone closes the mouth after saying, "I am resolved."

A somewhat long mouth, with an upward curve at the corners and with thin and very flexible lips, indicates wit. Voltaire had this sort of mouth.

Full, flexible lips, with a hollow in the centre of the lower lip, and with the corners turning upwards, show a joyous, hospitable and rather materialistic temperament, with good spirits and sense of humour.

A mouth with full lips, but in which one side of the lower lip is larger and fuller than the other, was said by the old writers to denote ardour in love and general sensuousness. It is one of the signatures of Venus.

A wart just above the upper lip shows a coarse and cruel nature; a mole in the same place, love of the opposite sex.

Of course, the shape and placing of the teeth are not without significance in the character given by the mouth. When the upper gum shows above the teeth directly the lips are open, it is a sign of a selfish and phlegmatic nature.

Short, small teeth are held by the old physiognomists to denote weakness and short life, whilst rather long teeth, if evenly set in the head, denote long life.

The more the teeth, in point of size, shape and arrangement, approach to those of the carnivorous animals, the more violent are the animal instincts in the person; whilst the more the human teeth in shape and position approach to those of the graminivorous animals, the more placid is the character.

Zain adwan

White, medium-sized and evenly-set teeth, which are seen as soon as the mouth is open, but which are never exposed—that is, which do not at any time show the gums—are a sign of good and honest natures.

Projecting teeth show rapacity; small, retreating teeth, such as are rarely seen unless in laughter, show weakness and want of physical and moral courage. The lower teeth projecting and closing over the upper range are indicative of a harsh nature.

In most faces the mouth or the nose is the more prominent. Where the nose is the dominant feature, energy, command and force of willpower, combined (unless the mouth and eyes show great kindness) with selfishness, show themselves in the character. Where the mouth, jaw and chin are more prominent, the appetites and passions are strong.

Broad jaws, with a broad forehead, mean both force of intellect and force of animal passion. Byron had this combination of brow and jaw; but the lips, which were full and flexible and with upward-curving corners, redeemed the sensuality given by the jaws, and the intellectual qualities shown by the form of the brow were in excess of the indications of voluptuousness given by the lower part of the face.

A person who has the jaw much broader than the brow and head has strong passions and a weak intellect—the very worst possible combination.

When the jaws are massive and yet the head and brow are more so, we have a powerful character, who can exert all his intellectual powers on one subject—one who has the very valuable faculty of concentration.

Where the jaws are much narrower than the head, we have a character where the sensual instincts are feeble, and where intellect is of a subtle and refined order. Wit is shown by this form of face, especially if the nose is delicately outlined, the tip pointed and somewhat drooping over the mouth.

Zaid n. adwan

When the lips retreat on each side of the mouth and open into an oval form, it denotes a subtle intelligence, tact and refinement of nature.

A sharp indentation immediately above the chin, between it and the lower lip, shows good understanding.

A pointed chin is a sign of craftiness, wisdom, discretion and intuitive perception.

A soft, fat, double chin shows epicurism and love of sensual pleasures of all sorts; it also indicates an indolent temperament. We never see such chins in persons of an energetic, restless nature. Charles James Fox, who was excessively indolent, had this chin even in youth.

A flat chin shows avarice and a cold, hard nature; a small chin indicates weakness, want of will-power and cowardice.

A retreating chin is a sign of silliness and, if the brow is shallow, of imbecility.

Where the space between the nose and the red part of the lip is short and very sharply cut, it indicates refinement and delicacy of perception, but not much power—no *force* of intellect; where this space is unusually short, it denotes silliness and weakness of purpose. A rather long but not flat upper lip, especially where the serpentine line of the middle of the mouth is much defined and the middle of the lip droops to the lower lip and is very flexible, denotes an eloquent person. We see this form of upper lip in the bust of Demosthenes, the greatest of Grecian orators; in Cicero, whose eloquence was unsurpassed in his age; in Fox, whose powers of oratory were great; in the demagogue Wilkes, in Edmund Burke, in Lord Palmerston and numerous other orators.

A very long upper lip, which is flat and which belongs to a straight and formless or too thick-lipped mouth, is a sign of a low and vicious type of character. Almost all the faces of great criminals have this defect, combined with massive jaws and high cheek-bones,

which last defect is, both Lavater and Perneti (a great French writer on the subject of physiognomy) tell us, a sign of rapacity and egotism.

A round chin, with a dimple in it, denotes kindliness and benevolence, a tender and unselfish nature. In a very massive double chin the dimple increases the quality of love of sensual pleasures. A square and massive chin shows strong perseverance and determined will.

An old Italian writer says that "women with brown, hairy moles on the chin, especially if these excrescences are on the under part of the chin, are industrious, active and are good housewives"; they are also, he says, "very sanguine and given to love follies. They talk much and whilst they are easily excited to return a love which is offered them, they are not so readily prevailed upon to become indifferent. For this reason," he goes on, evidently speaking feelingly and probably therefore with personal experience of the matter, "they should be treated with circumspect, calm friendship and kept at a distance by a mildly cold dignity of demeanour." He gives no directions as to how this effective "demeanour" is to be arrived at, but at once passes on to another remark on the subject of moles, and tells us that "a mole upon the upper lip, especially if it is bristly, will be found in no person who is not defective in something essential." This is rather a wide way of putting the matter. Are people with this blemish morally, mentally, or physically deficient? Wanting in kissableness such a mouth might be and this, perhaps, where lips are concerned, *is* "something essential."

CHAPTER XXXI.

THE HAIR AND THE EARS

Black hair which is perfectly without any wave or curl and which lies in lank, lifeless masses, shows a melancholic disposition; a black beard which grows sparsely gives the same indication.

Black hair which is wavy or curling and very thick, shows force of affection and a certain ardour in love matters; so also does a thick and crisp-textured black beard and moustache.

The lank, thin and uncurling black hair is one of the signatures of Saturn alone; the crisp, curling and thickly-growing black hair is the combination of Venus and Saturn. The united influence of these two planets on a life gives force of character, for the warmth and impulse given by Venus is tempered by the distrust of Saturn into prudence; thus people with the crisp dark hair get the ardour, combined with prudence, which produces success in life.

Chestnut hair of a soft and silky texture and not very thick, gives romance of character. This is not the sort of hair which is ever seen on very commonplace, realistic persons. Men having this soft chestnut-coloured hair are somewhat effeminate in their tastes and are wanting in energy and decision. Both men and women having it are incapable of strong affection: they are attracted by the opposite sex, but they are more given to having a series of small interests than one strong love. If this hair is found in combination with the golden coloured eyes it is indicative of coquetry in the nature; if with pale blue-grey eyes we have languor and caprice—a sentimental and inconsistent person.

Bright golden hair of a rich deep colour and of a crisp and waving texture growing thickly on the head and somewhat low on the brow, shows an ardent, poetic and artistic temperament. It is the signature of the Sun. Such people are generally fond of music, painting, or poetry. Both men and women having this sort of hair are intuitive in their judgments; they do not reason about things, they feel them; they are a little quick of

temper, that is, easily ruffled, but they are quickly appeased; they are gay and interest themselves in art, even if they are not artists themselves.

Persons with red hair are ardent and vivacious, especially if, with it, they have hazel eyes, in which case they have a bright and quick intelligence, for reddish hair and bright brown eyes are the signature of Mercury. They have a great deal of natural facility for study and good memories, but they are selfish and rather cruel.

Red hair, with blue eyes, shows the same warmth of character, but not so much intelligence, and if, with blue eyes and red hair, the eyebrows and eyelashes are white—as is often the case—it is an indication of a weak and capricious nature.

People with red-brown hair, which is very thick and redder over the ears and at the temples and on the beard than on the head, are courageous and hot-tempered. This coloured hair is the signature of the fiery planet Mars, and (unless the other indications in the face are widely different) shows activity and energy in all things. It augments the indications of force and power given by other features and in art gives sense of colour in painters—force of language and eloquence in poets—and power in musical composition.

Hair of that colourless, fair colour which French writers call *blond cendré*, or ash-coloured, denotes persons of an indolent and dreamy temperament. It is the indication given by the dominant influence of the Moon at birth. Persons with this sort of hair, in combination with large blue-grey eyes, with fair, long, but straight eyelashes and very slightly-defined eyebrows of the same blonde colour and white, soft skin, are capricious, languid, imaginative and somewhat melancholic. The imaginative and excessively indolent Théophile Gautier, the French novelist, was of this type in combination with Venus, giving a sensuousness amounting to sensuality.

zaid n. adwan

Women having this sort of colouring of skin and hair are romantic and devoted in a resigned, but not active spirit—that is, they are more generous in words than deeds, for they are incapable of exertion and still less of perseverance.

Persons with soft, wavy brown hair are affectionate, gentle and loving. Their first instincts are always good and kind. They like society and are gracious in manners and, though they are not quite as indolent as those having the soft ash-coloured hair—indicative of the Moon's influence—they are still lovers of repose and elegant comfort.

People with this soft brown hair (which is one of the signatures of the planet Venus) are very open to the impressions of beauty and they abhor noise, discords and quarrels; men with this sort of hair, like those with *pale* golden hair, are somewhat effeminate and are easily moved to tears.

Large, fleshy ears (especially those which have the lobes of the ears red) show coarseness of nature and sensuality.

If the ears stand forward so as to show their entire form when the face is seen from the front, it denotes rapacity and cruelty.

Long-shaped but small ears indicate refinement; a very small ear, close to the head, shows delicacy of perception, refinement, but also timidity.

The ears should be so placed as not to be higher than the eyebrow, or lower than the tip of the nose; if set in too sloping a direction they show timidity; if too upright, animal instincts, courage, amounting to cruelty, especially if they obtrude from the head.

A thin ear shows delicacy and poetry of feeling; a thick ear the reverse.

Middle-sized ears, rather close to the head, are the signature of Jupiter; large ears of Saturn; delicate, long-shaped ears of the Sun and also of Mercury, only those bearing the signature of Mercury are more coloured, whilst those of the Sun are pale.

zain adwan

Very upright ears, standing forward, are the signature of Mars; small, round ears, delicately tinted pink and close to the head, show the influence of Venus; whilst middle-sized round ears, of a very pale colour, are indicative of persons born under the influence of the Moon.

CHAPTER XXXII.

THE SIGNATURES OF THE PLANETS ON THE FACE

Those born under Jupiter have fresh complexions, and large blue or grey eyes, with thick and well-formed eyelids; and their eyelashes are long; their hair—which is chestnut, or, if tending towards black, is a brown, not *blue*, black—and is crisp or curly. They generally have well-marked and somewhat arched eyebrows, and their noses straight, with a slight rise on them, and somewhat fleshy; their mouths are large, but with generous, curved and full lips, the upper lip projecting over the lower one; their teeth are large, and the two in front are generally longer than the rest; their cheeks are fleshy and firm; the cheek-bones are well defined, without being prominent; the chin is large, with a dimple in the centre of it; their ears are of medium size and lie somewhat close to the head. The men born under Jupiter have thick curly brown beards, but they get bald early in life.

Those born under the dominant influence of the melancholy planet Saturn have no colour in their cheeks and their skin is dark and of a yellow or leaden tint. It is seldom that anyone is born under the *sole* influence of one planet; the ugliness of the Saturnian type is much mitigated by the influence of Jupiter, and the union of Venus and Saturn often produces positive beauty of a serious and melancholic sort. Many of the strikingly beautiful Spanish faces show the combined influence of these two planets.

zaid n. adwan

Those born under the dominant influence of the Sun have regular features and a soft skin of a yellowish tint, but with colour in the cheeks and lips. Their hair is of a *red*-gold tint; and their eyebrows are well defined, but not dark. Their eyes are of a golden brown or greenish grey, and are brilliant and well shaped; the eyelashes and eyebrows are a little darker than the hair, but not dark, and are traced in a long sweeping line extending to the temples. Their cheeks are well covered, without being plump; their jaws are a long oval and neither the cheek-bones nor the jaws are at all prominent. Their teeth are even, but of rather yellowish white; their mouths are neither large nor small, but well formed, with the lips meeting evenly, that is, neither the upper nor the lower lip projecting. Their ears are medium-sized, rather long in shape, lying close to the head and the lobes of them are fleshy and slightly coloured of a pinkish hue. The chin is rather prominent, round and well shaped, like those of the antique statues, but not fleshy. Those born under the influence of the Sun have frequently weak sight, especially if their birth has taken place during an eclipse.

Those born under the influence of Mercury have long faces and delicate, mobile features. Their skin is fine, soft and honey-coloured, but changes in tint with every passing emotion, for those born under Mercury are of a nervous, vividly intuitive and highly excitable temperament. Their hair is of a reddish, not golden, brown (what is called auburn), very fine and supple. Their foreheads are high and prominent and their eyebrows, which are long and delicately traced, lie very low over the eyes and are very mobile, moving up and down with every emotion. The eyes of those born under this planet are somewhat sunken, of a hazel or dark grey colour; they move quickly and have a restless expression; the white of the eye is (like that of those born under Saturn) of a yellowish tint and the lids of the eyes are thin and do not droop at all over the eyes. Their noses are straight and long, with delicate nostrils; the tip of the nose is round rather than pointed and frequently has a small cleft or dimple, which is, however, only faintly perceptible in certain lights, at the extreme tip. They have delicate mouths which

zaid n. adwan

droop a little at the corners and the lips are thin, mobile and often a little apart; the upper lip is thicker and more projecting than the lower lip; the teeth are small and even. The chin is long, pointed and a little projecting at the lip. The head is oval in shape and full at the temples.

Those born under the planet Mars have short, square-shaped, but small heads, with high foreheads on which the hair grows far back, leaving the forehead much exposed. Their faces are round, sometimes square at the lower part and their skin is hard and dry and of a red colour, especially about the ears, which are long-shaped, set straight rather high on the head and slightly projecting from it. Their eyebrows are short, sometimes stopping midway over the eyes, very bushy and lying close to the eyes. Between the eyebrows are several short upright wrinkles. The hair is of a red or sandy colour, coarse and very curly. The beards of men born under Mars are thick, short and of the same fiery colour as the hair. Their eyes are grey or red-brown and are large, round, very wide open and have a fierce and fixed glance; the white of the eye in those born under this fiery planet is often bloodshot. Their mouths are large, but the upper lip is thin and compressed; the lower lip is somewhat thicker than the upper lip. Their noses are short and aquiline, with dilated nostrils. Their chins are projecting and somewhat massive, for the jaw is strongly developed; the cheeks are somewhat hollow, and the cheek-bones very marked.

Those born under the influence of the Moon have round-shaped heads, broad at the temples (showing ideality—the Moon gives imagination). The forehead is full over the eyebrows, but retreats at the top; it is broad and low. The complexion is pale, almost colourless and the skin is soft. Their hair is fine, soft, of a colourless fairness, no golden tint in it and it is never very thick. The faces of those born under the dominant influence of the Moon are large and round; the nose is (in proportion to the face) small and short and its tip is round rather than pointed. Their eyes are of the same colour as the hair, very lightly marked, but joining over the nose. Their mouths are small; but their lips,

zaid n. adwan

which are of a pale colour, are full and pouting and are rarely quite closed. Their teeth are large and often irregular. Their chins are round, fleshy and retreating. Their ears are also round, medium size, pale coloured, set in a very sloping direction and lying close to the head. If born during an eclipse of the Moon, those born under this influence are sometimes blind.

People born under the influence of Venus have a great resemblance to those born under Jupiter, only their beauty is more feminine. They have the white and delicately-tinted skin of the Jupiterians, but it is still softer, finer and more transparent. They have round faces, the cheek-bones and the jaw-bones are not at all apparent; their cheeks are softly rounded and generally ornamented with dimples; their foreheads are a delicate oval, rather low and have delicate azure veins at the temples. The eyebrows of persons born under the influence of this beautiful planet are dark and beautifully marked in long sweeping but very delicate lines, but not meeting over the nose. Their hair is long, thick, soft, undulating and of a light brown colour. Their noses, which are broad at the root between the eyes, are straight and delicate, not at all pointed, but rather rounded at the tip;[20] the nostrils are round, but dilated and very flexible. Their eyes are large, clear, humid and somewhat projecting; the pupils are large in proportion to the white of the eye, which is limpid and of a clear, transparent, bluish white; their eyelids are well formed and blue veined. Their mouths are small and of a beautiful red colour; the lips are full, especially the lower one, the right side of which is slightly larger than the left. This is a particular Signature of Venus, as is also a small dimple near the corner of the mouth. The teeth are white, small, evenly set in coral-tinted gums and the chin is soft and round and has, like the chin of Jupiterians, a dimple in it.

Although the signs just described are those given by each planet, as it rarely happens that anyone is born under the influence of one planet only, but generally of two or more, it is rarely that we see a face which gives the pure type of any one planet without

admixture. It is for the physiognomist to examine and ascertain which is the dominant planet.

The union of Saturn and Jupiter gives a pale skin without freshness, chestnut hair and eyes and a rather dark skin, the face a round oval and dark grey eyes.

The union of Venus with the Sun gives brilliant beauty, a beautiful complexion, hair of a golden brown or rich chestnut, full, bright brown eyes with long eyelashes, a delicately-formed nose and a beautiful mouth. People born under this junction have much charm of manner, but they are not very constant; for, although they have much tenderness, they are of the ardent artistic nature, which, from its very susceptibility, cannot be expected to be as constant as those who are less impressionable; they are people of quick rather than deep feelings; they love readily, but as readily forget.

"Women born under the double influence of Venus and the Sun," says an old Italian writer on the subject, are "loving, lovely and beloved."

CHAPTER XXXIII.

CONCERNING THE MOLES ON THE FACE AND THEIR REFERENCE TO THOSE ON THE BODY

All moles are the result of the influences of the planets, or of the sign of the zodiac rising at birth. The moles which are given by Saturn are black; those by Jupiter are of a purple-brown colour; those by the Sun, yellow; by Venus, light brown; Mercury, honey-coloured; by the Moon, of a bluish white.

A mole on the right side of the forehead, just beneath or on the line of Saturn (see plate) indicates another on the right side of the breast. This mole shows to a man, if yellow, that he will have good fortune in sowing, tilling the earth, or building; if red, he will

zaid n. adwan

have luck all through his life, by his courage and force of character; if black, his condition will be changeable; if the mole is purple, he will be advanced to be the head of his family. In a woman a mole in this position shows fortune by inheritance or legacies; but if black in colour she will not live long.

A mole on the left side of the forehead on the Line of Saturn indicates another on the left side of the back and shows to a man imprisonment and disaster; if honey-coloured, his trouble comes from women; if red, from quarrels with enemies; if black, he will be unfortunate all his life. To a woman it foretells that she will live out of her own country and if black she will be a widow.

A mole in the middle of the forehead on the Line of Saturn shows another in the middle of the stomach and foretells to a man, if it should be black, that he will suffer much ill-fortune for the sake of women; if red, he will get some pleasure out of his troubles with them; and if yellow, he will rejoice through women; if of a pale bluish colour and raised, he will be much beloved of women. To a woman, of whatever colour it may appear, it indicates that she is of a very luxurious nature and will suffer from her own folly as regards men.

A mole on the right side of the forehead on the Line of Jupiter shows another on the right side over the liver and indicates, to a man, good fortune in marriage, long life and large possessions; but if black, he will not be quite so lucky as regards marriage. To a woman it shows, whatever its colour, good fortune in all that concerns her.

A mole on the left side of the forehead on the Line of Jupiter shows another on the left side of the stomach and indicates, to a man, love of material enjoyments, especially if it be of a purple colour; if honey-coloured, he is not so sensual. To a woman such a mole shows her to be imprudent and quite regardless of her own honour.

A mole in the middle of the Line of Jupiter shows another in the middle of the breast and indicates that a man is of a harsh nature; if red, he is furious in temper; if black, he

is singularly unfortunate in all his undertakings; but if raised and of a bluish colour, he is less unlucky. To a woman it indicates that she is foolish, prattling and idle.

A mole on the right side of the Line of Mars shows another on the right arm and indicates, if red, military distinction; if honey-coloured, good fortune with horses and other cattle; if black, danger from four-footed beasts; if much raised and somewhat red, it shows good fortune in all things relating to fire. To a woman this mole shows a rich husband, full of kindness and complacency.

A mole on the left side of the Line of Mars indicates another on the left arm, and shows a man to be of a quarrelsome nature; if black, he is treacherous and loses much by four-footed beasts and by horse-racing; if purple or yellow, he is involved in quarrels about women. Such a mole, whatever its colour, shows a woman to be very unfortunate in her love affairs, and likely to be betrayed by her female friends.

A mole in the middle of the Line of Mars indicates another on the left side of the belly; if red, the man is likely to be guilty of manslaughter and if any other colour he is sensual. To a woman this mole shows vanity and, if black, she is likely to be the cause of the death of some friend, but more by mischance than by design.

A mole on the right side of the forehead on the Line of the Sun indicates another on the right breast and intimates, to a man, of whatever colour but black, riches and honours; if black, his good fortune will not be so great and will come, not from his own merits, but from the exertions of friends. To a woman it shows an affluence of the goods of fortune; but if black she will have to be very subservient to her husband.

A mole near the right ear shows another on the right side of the belly, not low down and signifies, to a man, a blow on the head, some accident to that ear, whereby he may lose his hearing; if black, these evils are the more to be apprehended. To a woman it shows the loss of those things she most values.

zaid n. adwan

A mole on the left ear shows another on the left side, low down on the belly. This mole indicates to a man persecution from enemies. If it be of a red colour, that he will go near to committing murder by reason of women; if black, or even honey-coloured, it is still of evil indication and shows quarrels and violent death. To a woman, let it be of whatsoever colour, it shows that she will be the cause of death to someone; let her, therefore, shun to meddle with poison.

A mole on the right cheek shows another on the right hip and indicates, to a man, that he will have great charm of manner towards women, and be much beloved by them; this, whatever its colour. To a woman also it shows happy marriage and that she will be vehemently beloved.

A mole on the left cheek shows another on the left hip and indicates, to a man, a wandering existence and short life; if black, he dies by violence. To a woman it threatens sharp and hard fortune, especially in love matters.

A mole on the right side or corner of the mouth shows another at the right side of the lower part of the spine and shows, to a man, that he shall much increase his wealth by reason of his own sagacity; but if honey-coloured, his good fortune will come by women. To a woman such a mole shows she will abound in wealth and be vehemently beloved; if black in colour, with all these advantages, she will yet suffer from the scandal of envious women friends.

A mole on the left side of the mouth indicates another on the left side of the base of the spine and shows, to a man, that he will be entangled with a woman he cannot marry, and have illegitimate children. To a woman it shows a likelihood of the same disgrace.

A mole in the middle of the upper lip shows another on the lowest part of the body and indicates, to a man, that he will be miserable from various perils, but above all from women. To a woman this mole shows sickness and weakness from internal diseases.

zain.adwan

A mole beneath the middle of the under lip shows another on the knee and indicates, to a man, that he will undertake long and perilous journeys, by reason of which he shall see many strange countries; if honey-coloured, he will gain wealth from strangers and marry a rich, foreign wife. Such a mole shows a woman to be thoughtless and likely to marry a foreigner and live much out of her own country.

A mole upon the middle of the chin shows another upon the right foot and indicates, to a man, that he shall have good fortune through women. To a woman happy marriage, but worry for her children.

A mole on the right side of the chin shows another on the right haunch and indicates, to the man, that he will be of great intellectual capacity; if black, he will be a searcher in occult matters. In a woman it shows good fortune, happy marriage and long life, whatsoever may be its colour.

A mole on the left side of the chin shows another on the left haunch and indicates, to a man, inconstant fortune, much worry of mind and bodily discomfort. In a woman it shows ill-health and, if of a pale bluish colour, danger by water.

CHAPTER XXXIV.

CONCERNING THE MOLES WHICH HAVE NO CORRESPONDING MOLES ON THE FACE

A mole on the right side of the throat shows to a man great wit but short life, whatever may be its colour. To a woman it indicates a reasonably happy life, but danger and pain from childbirth.

A mole on the left side of the throat threatens a man with dangerous falls from horses or from high places. To a woman the same and, should the mole be of a pale colour, danger by water.

zaid n. adwan

A mole at the nape of the neck indicates to either man or woman great danger of untimely death by water.

A mole in the midst of the throat—that is, on the gullet—shows to a man much danger of death by strangulation or hanging. To a woman peril in sickness and, if the mole should be black in colour, she dies.

A mole immediately under the right breast shows to a man that he will be lucky in agriculture. To a woman that she shall receive inheritance from the dead; if black, her father is killed by accident.

A mole under the left breast shows a man to be of a malignant nature and furious of temper, but strong in love. To a woman it indicates great constancy and suffering by reason of that constancy.

A mole on the knee, whether left or right, predicts, to either man or woman, long and various journeys. Such persons will marry entirely for their own fancy, probably foreigners, and will be very fortunate in their marriages.

A mole on the calf of the right leg shows to a man that by his own ingenuity and learning he shall attain a high position; if black, he will receive some sorrow from women; but if the mole should appear *raised* he marries a lovely person—has only one wife and lives happily. To a woman it shows a fortunate, good and rich husband and that she will have many children and live long.

A mole on the lowest part of the body shows to a man that he is of a very luxurious nature and that he shall be enriched by marriage. A woman having this mole is rather sensuous, but—on the whole—faithful to her husband.

A mole on the right shoulder shows a man to be fortunate in his undertakings; if red, he has a large fortune with his wife. To a woman it indicates a marriage above her expectations; but if black, she buries her first husband and marries again.

zaid.adwan

A mole on the right foot shows to a man that he will be clever in acquiring foreign languages and that he will be a great student of occult matters. To a woman it promises a fortunate and happy, long life; if black, this good fortune is somewhat chequered with troubles.

A mole on the left foot denotes a man to be rash and of an evil and vagabond disposition. To a woman it shows much care and trouble and, if black, danger in travelling.

If the second toe in a foot should stretch out much beyond the great toe, it shows, to either man or woman, riches and a happy and prosperous life.

A mole on the left shoulder predicts to a man much worry in money matters. To a woman it shows a life of continual anxiety and humiliation by reason of her own vanity. If black in colour, she suffers some serious disgrace from her own conduct.

A mole on the lower part of the neck on the right side near the shoulder shows a man to be very covetous. To a woman it indicates that she will be beloved of princes or great personages far above her in rank.

A mole on the neck near the left shoulder indicates to either man or woman disgrace from evil practices.

CHAPTER XXXV.

CONCERNING THE MARKS GIVEN AT BIRTH BY THE SIGNS OF THE ZODIAC

By a knowledge of the signature given by the signs of the zodiac, when rising at birth, we may sometimes ascertain the hour of nativity, or, at any rate, go near enough to it to be able to work out the horoscope after a fashion, supposing the exact date to be impossible of attainment.

zaid n. adwan

A person born when the first part of the sign Aries is rising will have a small raised mole amongst the hairs of the head; if the second part of the sign happened to be rising at the birth, the mark or mole would be raised in the form of a pea or wart and would be seen on the forehead; if the third part of the sign arose at birth, the mark would appear below the mouth, or towards the chin. Those persons having these marks of Aries on any of the parts described will generally be found to have the mark of Mars in the lowest part of the body, also in the form of a raised mole or wart.

When Taurus is rising at a birth, the native bears a mark in the front of the throat, sometimes in the form of a raspberry or red-coloured mole, which mark is always ill in its effects. Should the second part of the sign Taurus have been rising at the nativity, the person will have the mark at the side of the throat. If the third, the same mark will appear on the nape of the neck, but then it will be more raised than the two former moles.

Those born under Gemini have their marks in the arms. If the first part of the sign arose at birth, they bear its mark on the right arm, near the shoulder; if the second, on the same part of the left arm and if the third part of the sign arises at birth, the native bears the mark on the right arm, but below the elbow and generally near the wrist.

When the sign Cancer is in the ascendant, the mark is on the upper part of the right breast in the form of a flower or a hare's foot, of a whitish colour, and commonly having a hair or two springing from it. In the older days this mark was supposed to be an evidence of witchcraft in a woman and many poor creatures have lost their lives for this. Those born under the second part of the sign Cancer have the mark lower down on the breast and when the third part of Cancer is rising at a birth, the sign is nearly under the breast.

When Leo is in the ascendant at birth, the sign is on the left breast and, in the same manner, if the sign appears high up on the breast it indicates that the first part of the

sign was ascending; if near the middle, the second; and if on one side, towards the left armpit, the third part of the sign must have been ascending at birth.

In nativities under Virgo the mark is on the upper part of the stomach, that is, between the two breasts, when the first part of the sign ascends; those born when the second part is rising have the mark near the navel; and those when the third part is rising quite low down on the stomach. Those that are thus marked are very inconstant. The moles given by Virgo are flat, and of a reddish colour.

When Libra is in the ascendant, the marks are raised like warts, and are small, soft, and hairy; when the first part of the sign is rising the mark is near the loins; when the second, towards the centre of the stomach and the third part of the sign throws the mark to quite the lower part of the body.

Those born under Sagittarius have the mark of the sign in the thighs and these moles are raised like bulbs and are very big. When the first part of the sign is rising, the mark is on the right thigh; when the second part is rising, on the left thigh and those who have the third part of Sagittarius rising at their birth are so marked on the right haunch.

Those born under Capricornus have the marks on the knees, which marks are quite flat. When the first part is rising, the mark is on the right knee; when the second, on the left, and when the third, the mole is under the knee.

It will be remembered that the sign Aquarius governs the legs; therefore those who are born with this sign ascending have the mark of it (which is a long-shaped mole) on the right leg (this mark shows extreme inconstancy); when the sign Scorpio is rising at birth there is a dark mole on the belly showing ill fortune.

The sign Pisces, or the Fishes, governs the feet; therefore those who have this sign in their ascendant are marked on the feet. Those born under the first part have the marks (which are ordinary flat moles) on the right foot; those under the second, on the left;

Zaid H. adwan

and those on the third, on the soles of the feet or on the heels. These last are called the Royal marks; they are large moles inclining to red, and those who are marked in those places are assured of honours and dignities.

ALFRIDARY FOR A DIURNAL NATIVITY.

ALFRIDARY FOR A NOCTURNAL NATIVITY.

To face Chapter XXXVI.

CHAPTER XXXVI.

CONCERNING ALFRIDARIES

This word is taken from the Greek and refers to the certain time or number of years of the several planets which, in those years, dispense their benevolence or malignity according to their natures.

It will be observed from the plate at the beginning of this chapter, that each of the planets has his Alfridary, one after the other—and in this table will be seen the number of years in which each planet more particularly governs the life.

In all diurnal nativities the Sun begins the first Alfridary, and has seven years of government; Venus succeeds, having seven years of Alfridary; then Mercury, who has seven years of government. After him the Moon rules the existence for seven years; then Saturn for the same number; Jupiter succeeds him for seven years; afterwards Mars dominates the existence for seven years; after which the Dragon's Head and Dragon's Tail influence the life for three years; and then the Sun has five more years of government, when the life probably ends.

Those that are born in the night have their first Alfridaric years from the Moon, which are seven, followed by those of Saturn, who has seven years; after him Mars is dominant for seven years; then the Sun for the same number of years; succeeded by Venus and Mercury, each only seven years.

The years of an Alfridary are eighty-two—namely, the Moon, seven; Saturn, seven; Jupiter, seven; Mars, seven; the Sun, seven; Venus, seven; Mercury, seven; the Dragon's Head, three; the Dragon's Tail, two. These two last have their Alfridaric years separate from the others, and they are those which exceed the seventy years of life, which are weak and feeble. For these signs are not (as we have seen) planets, but only symbols of a place in the zodiac representing the Moon's north and south nodes.

It will be noticed in these tables that, after the years of seventy-five, the Sun in a diurnal nativity, and the Moon in a nocturnal nativity, take up again their government, as at the

Zaid n. adwan

beginning of the life. These tables are interesting, as shadowing forth the dates of the events of the subject's life.

Those born under the Sun marry early, whilst those in whose nativity the Moon is powerful, generally marry rather late than early. In either nativity, when Saturn comes up, sorrows by death, sickness and loss of money may be expected; whilst, when Mars is powerful, evils of a strong and sudden nature appear, such as accidents, sudden deaths, quarrels and contentions of a vexatious character.

Those born under the Moon have very often serious and passionate loves quite late in life; this is accounted for in some measure by the fact that Venus has seven years of government in a nocturnal nativity from the age of fifty to fifty-seven. The age of forty-four, in a diurnal nativity, would be likely to bring about some misfortune during that year of the native's life, *both the infortunes*, Saturn and Mars, being then powerful. The same thing occurs in a nocturnal nativity at the age of thirteen, from which age up to twenty there is not much good fortune; it will be remembered that the latter part of the life of a person born at night is generally much happier and altogether more fortunate than the earlier years of existence.

CHAPTER XXXVII.

CONCERNING THE MYSTICAL WHEEL OF PYTHAGORAS AND THE METHODS OF WORKING IT

This mystical figure is copied from a work in old French on Chiromancy and Geomancy, compiled by the Sieur de Peruchio, and published at Paris in 1657.

Arithmancy, or divination by numbers, on which the working of this figure depends, was much practised in various ways during the Middle Ages; and much confidence

zaid n. adwan

appears to have been placed in this wheel of Pythagoras, which resolves questions by a species of sortilegy by numbers, in which the result depends upon the unfettered agency of the mind and will, or the serious intent to know any difficult thing. The wheel is said by the old-world writers to be able "to resolve all questions on all matters upon the result of which the querent desires information, whether of the past, present, or future."

Concerning the method of working it, the Sieur de Peruchio gives the following explanations:—

The wheel, it will be perceived, is divided into four equal parts, the upper part of which contains the numbers which are *fortunate*, and the lower half those which are *unfortunate*. Around the wheel are seen the letters of the Alphabet, above which are placed certain corresponding numbers, which are required in the calculations.

The following table gives the numbers to be chosen by chance (as will be explained further on) in working the questions:—

1	11	22	28	29
6	2	12	23	30
15	7	3	13	24
19	16	8	4	14
25	20	17	9	5
27	26	21	18	10

The inquirer, whilst thinking *earnestly* upon the matter he wishes resolved by the wheel, must choose a number out of the above Table.

This is better done with the eyes closed, and the number pricked out with a pin, so that there may be no premeditation in the choice. To this number, thus chosen, the inquirer

must add the number answering to the first letter of his first name, which number is seen in the wheel itself where the numbers are above the letters of the alphabet. To this number must be added the number of the day of the week on which the question is asked and of the planet ruling that day. Then add all these numbers together and divide the sum by 30 as often as it can be done. Then look for that number which is the remainder in the inner circle of the wheel; observing in what part of the wheel it falls should there happen to be *no* remainder, then the number 30 must be looked for. If the question to be propounded should be whether anything about to be undertaken will succeed or not, should the number fall in the *upper* part of the wheel the matter will have a happy issue; but if, on the contrary, the number appears on the *lower* part of the wheel the thing in question will not be a success. In any question where time is concerned as, for instance, as regarding how long or how short shall be the matter in hand it must be borne in mind that the numbers in the right half of the wheel represent *long time*—that is, that the event about which the question is asked will be some time before it comes to pass; whilst those in the left half of the wheel signify *short* time—and so, whether for good or evil, shall the business quickly or slowly come to pass.

All questions are thus to be asked but *one*, and that is, whether a sick person shall recover or die; in which case, after proceeding to add the numbers of the Christian name, the day of the week and the planet, the number representing the Moon's age on the day the question is asked must also be added; for example, if a person whose name is Veronica—asks on a Wednesday, 20th day of the Moon, if a sick friend should live or die, and chooses from the Table the number of 23, the matter would be worked thus:—

Number chosen	23
Number answering to the letter V	9
Number answering to Wednesday	102
Number answering to the planet Mercury	114

Number of the age of the Moon	20
	268

This, divided by 30, leaves 28 remainder, which will be found to fall in the unfortunate part of the wheel, showing that her friend will *not* recover.

The following table of the mystical numbers representing the planets, and also those belonging to the days of the week which each planet governs, is of much importance in working the wheel:—

PLANETS.		DAYS OF THE WEEK.	
♄ Saturn	55	Saturday	45
♃ Jupiter	78	Thursday	31
♂ Mars	39	Tuesday	52
☉ Sun	34	Sunday	106
♀ Venus	45	Friday	68
☿ Mercury	114	Wednesday	102
☽ Moon	45	Monday	52

These several numbers attributed to the days of the week, as well as those of the planet ruling the day, are of very ancient origin and are, probably, as well as the wheel itself, a relic of former *traditional* foreknowledge by lots and numbers.

There are certain days, however, which are evil days, on which no question should be asked of the wheel of Pythagoras. These days are as follows:—

- Of January, the 3rd, 4th, 5th, 9th and 11th.
- Of February, the 7th, 13th, 17th and 19th.

Zaid n. adwan

- Of March, the 13th, 15th and 16th.
- Of April, the 5th and 14th.
- Of May, the 8th and 14th.
- June has but one ill day, which is the 6th.
- July has two, the 16th and the 19th.
- August has also only two, the 8th and 16th.
- September has three, the 1st, 15th and 16th.
- October has only one ill day, which is the 16th.
- November has two, the 15th and 16th.
- December has three, the 6th, 7th and 11th.

This is a very old tradition, and in mediæval ages these days were universally shunned as "ruled by evil influences." In conclusion, those consulting the wheel of Pythagoras are advised not to ask more than one question on the same day and to refrain from all gibing, sporting, or jesting, and—above all—from all unbelief whilst making use of this mystical wheel in order to know the truth.

ENVOY.

Go—little book—and teach the present age something of the wisdom bequeathed us by the Past.

Footnotes

[1]

The ambient means the heavens when spoken of in a general manner.

[2]

Saturn, Mercury and the Moon.

zaid n. adwan

[3]

Aries is always opposite to Libra; Taurus to Scorpio; and so on of all the rest, as shown by the table given (p. 11).

[4]

The foregoing chapter explains this term.

[5]

The Chaldees averred that when Saturn was powerful in a nativity the person then born was "mystical and confederate in secrecy."

[6]

This animal has been probably assigned to him by reason of its sagacity and extreme fidelity--constancy in feeling being one of the attributes given by the planet Saturn when well-dignified.

[7]

Zadkiel's and Raphael's are both good; the following figure is worked after the Ephemeris of the latter.

[8]

The nebulous mass in the body of the Crab.

[9]

Hyleg is the word used for that body or point which is the giver of life.

[10]

This was the case at the birth of George the Third of England; at that of the Emperor Paul of Russia; Maria, Queen of Portugal; Charles the Second, King of Spain; and Murad the Fifth, Sultan of Turkey; and all these sovereigns, as is well known, became insane.

[11]

At Admiral Nelson's birth Mars was rising in the sign Scorpio.

[12]

zaid n. adwan

Probably vivisectionists.

[13]

These aspects can all be judged from the Ephemeris of the year of birth.

[14]

And these secondary directions being so much easier to calculate, students are advised to follow the ancient methods in this as in all else relating to this old-world study.

[15]

Translated from a Hebrew manuscript found near Cairo in 1836 at the time of the removal of the obelisk to France.

Adda-Nari, Nature--that is, the deity known under the name of Isis by the Egyptians.

zaid n. adwan

The date of this event would be determined by the place where the separation line crosses the Line of Fate.

If the Sun is one of the dominant planets, the Line of Heart broken under the Mount of the Sun shows serious physical affection of the heart; if this sign is on both hands it is fatal.

If the Head Line it placed very low, then the date where it crosses the Saturnian Line would be 30, and if the Heart Line is proportionately low the date where it crosses the Saturnian would be 45 years.

The noses of those born under Venus are frequently slightly upturned at the tip; they are never bent downwards over the lips.

The Project Gutenberg eBook of Mathematical Recreations and Essays, by W. W. Rouse Ball This eBook is for the use of anyone anywhere in the United States and most other parts of the world at no cost and with almost no restrictions whatsoever. You may copy it, give it away or re-use it under the terms of the Project Gutenberg License included with this eBook or online at www.gutenberg.org. If you are not located in the United States, you will have to check the laws of the country where you are located before using this eBook. Title: Mathematical Recreations and Essays Author: W. W. Rouse Ball Release Date: October 8, 2008 [EBook #26839] [Most recently updated: October 19, 2021] Language: English Character set encoding: UTF-8 Produced by Joshua Hutchinson, David Starner, David Wilson and the

Online Distributed Proofreading Team at https://www.pgdp.net Revised by David Wilson *** START OF THE PROJECT GUTENBERG EBOOK MATHEMATICAL RECREATIONS *** First Edition, Feb. 1892. Reprinted, May, 1892. Second Edition, 1896. Reprinted, 1905. MATHEMATICAL RECREATIONS AND ESSAYS BY W.W. ROUSE BALL Fellow and Tutor of Trinity College, Cambridge. FOURTH EDITION London: MACMILLAN AND CO., Limited NEW YORK: THE MACMILLAN COMPANY 1905 [All rights reserved.] Produced by Joshua Hutchinson, David Starner, David Wilson and the Online Distributed Proofreading Team at https://www.pgdp.net Transcriber's notes Most of the open questions discussed by the author were settled during the twentieth century. The author's footnotes are labelled using printer's marks* ; footnotes showing where corrections to the text have been made are labelled numerically1 . Minor typographical corrections are documented in the LATEX source. This document is designed for two-sided printing. Consequently, the many hyperlinked cross-references are not visually distinguished. The document can be recompiled for more comfortable on-screen viewing: see comments in source LATEX code. 'Character set encoding' refers to the LATEX source. PREFACE TO THE FIRST EDITION. The following pages contain an account of certain mathematical recreations, problems, and speculations of past and present times. I hasten to add that the conclusions are of no practical use, and most of the results are not new. If therefore the reader proceeds further he is at least forewarned. At the same time I think I may assert that many of the diversions— particularly those in the latter half of the book—are interesting, not a few are associated with the names of distinguished mathematicians, while hitherto several of the memoirs quoted have not been easily accessible to English readers. The book is divided into two parts, but in both parts I have included questions which involve advanced mathematics. The first part consists of seven chapters, in which are included various problems and amusements of the kind usually called mathematical recreations. The questions discussed in the first of these chapters are connected with arithmetic; those in the second with geometry; and those in the third relate to mechanics. The fourth chapter contains an account of some miscellaneous problems which involve both number and situation; the fifth chapter contains a concise account of magic squares; and the sixth and seventh chapters deal with some unicursal iii iv PREFACE problems. Several of the questions mentioned in the first three chapters are of a somewhat trivial character, and had they been treated in any standard English work to which I could have referred the reader, I should have pointed them out. In the absence of such a work, I thought it best to insert them and trust to the judicious reader to omit them altogether or to skim them as he feels inclined. The second part consists of five chapters, which are mostly historical. They deal respectively with three classical problems in geometry— namely, the duplication of the cube, the trisection of an angle, and the quadrature of the circle—astrology, the

hypotheses as to the nature of space and mass, and a means of measuring time. I have inserted detailed references, as far as I know, as to the sources of the various questions and solutions given; also, wherever I have given only the result of a theorem, I have tried to indicate authorities where a proof may be found. In general, unless it is stated otherwise, I have taken the references direct from the original works; but, in spite of considerable time spent in verifying them, I dare not suppose that they are free from all errors or misprints. I shall be grateful for notices of additions or corrections which may occur to any of my readers. W.W. ROUSE BALL Trinity College, Cambridge. February, 1892. NOTE TO THE FOURTH EDITION. In this edition I have inserted in the earlier chapters descriptions of several additional Recreations involving elementary mathematics, and I have added in the second part chapters on the History of the Mathematical Tripos at Cambridge, Mersenne's Numbers, and Cryptography and Ciphers. It is with some hesitation that I include in the book the chapters on Astrology and Ciphers, for these subjects are only remotely connected with Mathematics, but to afford myself some latitude I have altered the title of the second part to Miscellaneous Essays and Problems. W.W.R.B. Trinity College, Cambridge. 13 May, 1905. v TABLE OF CONTENTS. PART I. Mathematical Recreations. Chapter I. Some Arithmetical Questions. PAGE Elementary Questions on Numbers (Miscellaneous) . . . . . 4 Arithmetical Fallacies . . . . . 20 Bachet's Weights Problem . . . . . 27 Problems in Higher Arithmetic . . . . . 29 Fermat's Theorem on Binary Powers . . . . . 31 Fermat's Last Theorem . . . . . 32 Chapter II. Some Geometrical Questions. Geometrical Fallacies . . . . . 35 Geometrical Paradoxes . . . . . 42 Colouring Maps . . . . . 44 Physical Geography . . . . . 46 Statical Games of Position . . . . . 48 Three-in-a-row. Extension to p-in-a-row . . . . . 48 Tesselation. Cross-Fours . . . . . 50 Colour-Cube Problem . . . . . 51 vi TABLE OF CONTENTS. vii PAGE Dynamical Games of Position . . . . . 52 Shunting Problems . . . . . 53 Ferry-Boat Problems . . . . . 55 Geodesic Problems . . . . . 57 Problems with Counters placed in a row . . . . . 58 Problems on a Chess-board with Counters or Pawns . . . . 60 Guarini's Problem . . . . . 63 Geometrical Puzzles (rods, strings, &c.) . . . . . 64 Paradromic Rings . . . . . 64 Chapter III. Some Mechanical Questions. Paradoxes on Motion . . . . . 67 Force, Inertia, Centrifugal Force . . . . . 70 Work, Stability of Equilibrium, &c. . . . . 72 Perpetual Motion . . . . . . 75 Models . . . . . 78 Sailing quicker than the Wind . . . . . 79 Boat moved by a rope inside the boat . . . . . 81 Results dependent on Hauksbee's Law . . . . . 82 Cut on a tennis-ball. Spin on a cricket-ball . . . . . 83 Flight of Birds . . . . . .

. . . . . 85 Curiosa Physica . . . . . 86 Chapter IV. Some Miscellaneous Questions. The Fifteen Puzzle . . . . . 88 The Tower of Hanoï . . . . . 91 Chinese Rings . . . . . 93 The Eight Queens Problem . . . . . 97 Other Problems with Queens and Chess-pieces . . . . . 102 The Fifteen School-Girls Problem . . . . . 103 viii TABLE OF CONTENTS. PAGE Problems connected with a pack of cards . . . . . 109 Monge on shuffling a pack of cards . . . . . 109 Arrangement by rows and columns . . . . . 111 Determination of one out of 1 2 n(n + 1) given couples . . . . 113 Gergonne's Pile Problem . . . . . 115 The Mouse Trap. Treize . . . . . 119 Chapter V. Magic Squares. Notes on the History of Magic Squares . . . . . 122 Construction of Odd Magic Squares . . . . . 123 Method of De la Loubère . . . . . 124 Method of Bachet . . . . . 125 Method of De la Hire . . . . . 126 Construction of Even Magic Squares . . . . . 128 First Method . . . . . 129 Method of De la Hire and Labosne . . . . . 132 Composite Magic Squares . . . . . 134 Bordered Magic Squares . . . . . 135 Hyper-Magic Squares . . . . . 136 Pan-diagonal or Nasik Squares . . . . . 136 Doubly Magic Squares . . . . . 137 Magic Pencils . . . . . 137 Magic Puzzles . . . . . 140 Card Square . . . . . 140 Euler's Officers Problem . . . . . 140 Domino Squares . . . . . 141 Coin Squares . . . . . 141 Chapter VI. Unicursal Problems. Mathematical Recreations. "Les hommes ne sont jamais plus ingénieux que dans l'invention des jeux; l'esprit s'y trouve à son aise. . . . Après les jeux qui dépendent uniquement des nombres viennent les jeux où entre la situation. . . . Après les jeux où n'entrent que le nombre et la situation viendraient les jeux où entre le mouvement. . . . Enfin il serait a souhaiter qu'on eût un cours entier des jeux, traités mathématiquement." (Leibnitz: letter to De Montmort, July 29, 1715.) 1 CHAPTER I. SOME ARITHMETICAL QUESTIONS. The interest excited by statements of the relations between numbers of certain forms has been often remarked. The majority of works on mathematical recreations include several such problems, which are obvious to any one acquainted with the elements of algebra, but which to many who are ignorant of that subject possess the same kind of charm that some mathematicians find in the more recondite propositions of higher arithmetic. I shall devote the bulk of this chapter to these elementary problems, but I append a few remarks on one or two questions in the theory of numbers. Before entering on the subject of the chapter, I may add that a large proportion of the elementary questions mentioned here and in the following two chapters are taken from one of two sources. The first of these is the classical Problèmes plaisans et délectables, by C.G. Bachet, sieur de Méziriac, of which the first edition was published in 1612 and the second in 1624:

it is to the edition of 1624 that the references hereafter given apply. Several of Bachet's problems are taken from the writings of Alcuin, Pacioli di Burgo, Tartaglia, or Cardan, and possibly some of them are of oriental origin, but I have made no attempt to add such references. The other source to which I alluded above is Ozanam's Récréations mathématiques et physiques. The greater portion of the original edition, published in two volumes at Paris in 1694, was a compilation from the works of Bachet, Leurechon, Mydorge, van Etten, and Oughtred: this part is excellent, but the same cannot be said of the additions due to Ozanam. In the Biographie Universelle allusion is made to subsequent editions issued in 1720, 1735, 1741, 1778, 2 CH. I] ARITHMETICAL RECREATIONS. 3 and 1790; doubtless these references are correct, but the following editions, all of which I have seen, are the only ones of which I have any knowledge. In 1696 an edition was issued at Amsterdam. In 1723— six years after the death of Ozanam—one was issued in three volumes, with a supplementary fourth volume, containing (among other things) an appendix on puzzles: I believe that it would be difficult to find in any of the books current in England on mathematical amusements as many as a dozen puzzles which are not contained in one of these four volumes. Fresh editions were issued in 1741, 1750 (the second volume of which bears the date 1749), 1770, and 1790. The edition of 1750 is said to have been corrected by Montucla on condition that his name should not be associated with it; but the edition of 1790 is the earliest one in which reference is made to these corrections, though the editor is referred to only as Monsieur M***. Montucla expunged most of what was actually incorrect in the older editions, and added several historical notes, but unfortunately his scruples prevented him from striking out the accounts of numerous trivial experiments and truisms which overload the work. An English translation of the original edition appeared in 1708, and I believe ran through four editions, the last of them being published in Dublin in 1790. Montucla's revision of 1790 was translated by C. Hutton, and editions of this were issued in 1803, in 1814, and (in one volume) in 1840: my references are to the editions of 1803 and 1840. I proceed now to enumerate some of the elementary questions connected with numbers which for nearly three centuries have formed a large part of most compilations of mathematical amusements. They are given here mainly for their historical—not for their arithmetical— interest; and perhaps a mathematician may well omit them, and pass at once to the latter part of this chapter. These questions are of the nature of tricks or puzzles and I follow the usual course and present them in that form. I may note however that most of them are not worth proposing, even as tricks, unless either the modus operandi is disguised or the result arrived at is different from that expected; but, as I am not writing on conjuring, I refrain from alluding to the means of disguising the operations indicated, and give merely a bare enumeration of the steps essential to the success of the method used, though I may recall the

fundamental rule that no trick, however good, will bear immediate repetition, and that, if it is 4 ARITHMETICAL RECREATIONS. [CH. I necessary to appear to repeat it, a different method of obtaining the result should be used. To find a number selected by some one. There are innumerable ways of finding a number chosen by some one, provided the result of certain operations on it is known. I confine myself to methods typical of those commonly used. Any one acquainted with algebra will find no difficulty in modifying the rules here given or framing new ones of an analogous nature. First Method * . (i) Ask the person who has chosen the number to treble it. (ii) Enquire if the product is even or odd: if it is even, request him to take half of it; if it is odd, request him to add unity to it and then to take half of it. (iii) Tell him to multiply the result of the second step by 3. (iv) Ask how many integral times 9 divides into the latter product: suppose the answer to be n. (v) Then the number thought of was 2n or 2n + 1, according as the result of step (i) was even or odd. The demonstration is obvious. Every even number is of the form 2n, and the successive operations applied to this give (i) 6n, which is even; (ii) 1 2 6n = 3n; (iii) 3 × 3n = 9n; (iv) 1 9 9n = n; (v) 2n. Every odd number is of the form 2n + 1, and the successive operations applied to this give (i) 6n + 3, which is odd; (ii) 1 2 (6n + 3 + 1) = 3n + 2; (iii) 3(3n + 2) = 9n + 6; (iv) 1 9 (9n + 6) = n + a remainder; (v) 2n + 1. These results lead to the rule given above. Second Method† . Ask the person who has chosen the number to perform in succession the following operations. (i) To multiply the number by 5. (ii) To add 6 to the product. (iii) To multiply the sum by 4. (iv) To add 9 to the product. (v) To multiply the sum by 5. Ask to be told the result of the last operation: if from this product 165 is subtracted, and then the remainder is divided by 100, the quotient will be the number thought of originally. For let n be the number selected. Then the successive operations applied to it give (i) 5n; (ii) 5n + 6; (iii) 20n + 24; (iv) 20n + 33; (v) 100n + 165. Hence the rule. Third Method‡ . Request the person who has thought of the number to perform the following operations. (i) To multiply it by any number you like, say, a. (ii) To divide the product by any number, * Bachet, Problèmes plaisans, Lyons, 1624, problem i, p. 53. † A similar rule was given by Bachet, problem iv, p. 74. ‡ Bachet, problem v, p. 80. CH. I] ELEMENTARY TRICKS AND PROBLEMS. 5 say, b. (iii) To multiply the quotient by c. (iv) To divide this result by d. (v) To divide the final result by the number selected originally. (vi) To add to the result of operation (v) the number thought of at first. Ask for the sum so found: then, if ac/bd is subtracted from this sum, the remainder will be the number chosen originally. For, if n was the number selected, the result of the first four operations is to form nac/bd; operation (v) gives ac/bd; and (vi) gives n + (ac/bd), which number is mentioned. But ac/bd is known; hence, subtracting it from the number mentioned, n is found. Of course a, b, c, d may have any numerical values it is liked to assign to them. For example, if a = 12, b = 4, c = 7, d = 3 it is sufficient to subtract 7 from the final result in order to obtain the number originally

selected. Fourth Method * . Ask some one to select a number less than 90. (i) Request him to multiply it by 10, and to add any number he pleases, a, which is less than 10. (ii) Request him to divide the result of step (i) by 3, and to mention the remainder, say, b. (iii) Request him to multiply the quotient obtained in step (ii) by 10, and to add any number he pleases, c, which is less than 10. (iv) Request him to divide the result of step (iii) by 3, and to mention the remainder, say d, and the third digit (from the right) of the quotient; suppose this digit is e. Then, if the numbers a, b, c, d, e are known, the original number can be at once determined. In fact, if the number is 9x + y, where x ⩾ 9 and y ⩾ 8, and if r is the remainder when a − b + 3(c − d) is divided by 9, we have x = e, y = 9 − r. The demonstration is not difficult. For if the selected number is 9x+y, step (i) gives 90x+10y+a; (ii) let y+a = 3n+b, then the quotient obtained in step (ii) is 30x+3y+n; step (iii) gives 300x+30y+10n+c; (iv) let n + c = 3m + d, then the quotient obtained in step (iv) is 100x + 10y + 3n + m, which I will denote by Q. Now the third digit in Q must be x, because, since y ⩾ 8 and a ⩾ 9, we have n ⩾ 5; and since n ⩾ 5 and c ⩾ 9, we have m ⩾ 4; therefore 10y + 3n + m ⩾ 99. Hence the third or hundreds digit in Q is x. Again, from the relations y + a = 3n + b and n + c = 3m + d, we have 9m − y = a − b + 3(c − d): hence, if r is the remainder when a−b+3(c−d) is divided by 9, we have y = 9−r. [This is always true, if we make r positive; but if a−b+3(c−d) is negative, it is simpler to take y as equal to its numerical value; or we may prevent the occurrence of * Educational Times, London, May 1, 1895, vol. xlviii, p. 234. 6 ARITHMETICAL RECREATIONS. [CH. I this case by assigning proper values to a and c.] Thus x and y are both known, and therefore the number selected, namely 9x + y, is known. Fifth Method * . Ask any one to select a number less than 60. (i) Request him to divide it by 3 and mention the remainder; suppose it to be a. (ii) Request him to divide it by 4, and mention the remainder; suppose it to be b. (iii) Request him to divide it by 5, and mention the remainder; suppose it to be c. Then the number selected is the remainder obtained by dividing 40a + 45b + 36c by 60. This method can be generalized and then will apply to any number chosen. Let a ′ , b′ , c′ , . . . be a series of numbers prime to one another, and let p be their product. Let n be any number less than p, and let a, b, c, . . . be the remainders when n is divided by a ′ , b′ , c′ , . . . respectively. Find a number A which is a multiple of the product b ′ c ′d ′ · · · and which exceeds by unity a multiple of a ′ . Find a number B which is a multiple of a ′ c ′d ′ · · · and which exceeds by unity a multiple of b ′ ; and similarly find analogous numbers C, D, ... Rules for the calculation of A, B, C, . . . are given in the theory of numbers, but in general, if the numbers a ′ , b′ , c′ , . . . are small, the corresponding numbers, A, B, C, . . . can be found by inspection. I proceed to show that n is equal to the remainder when Aa + Bb + Cc + · · · is divided by p. Let N = Aa+Bb+Cc+· · · , and let M(x) stand for a multiple of x. Now A = M(a ′) + 1, therefore Aa = M(a ′) + a. Hence, if the first term in N, that is Aa, is divided by a ′ , the remainder is a. Again, B is a multiple of a ′

c ’d ’ · · · . Therefore Bb is exactly divisible by a ’ . Similarly Cc, Dd, . . . are each exactly divisible by a ’ . Thus every term in N, except the first, is exactly divisible by a ’ . Hence, if N is divided by a ’ , the remainder is a. But if n is divided by a ’ , the remainder is a. Therefore N − n = M(a ’). Similarly N − n = M(b ’), N − n = M(c ’), ... But a ’ , b’ , c’ , . . . are prime to one another. ∴ N − n = M(a ’ b ’ c ’ · · ·) = M(p), that is, N = M(p) + n . * Bachet, problem vi, p. 84: Bachet added, on p. 87, a note on the previous history of the problem. CH. I] ELEMENTARY TRICKS AND PROBLEMS. 7 Now n is less than p, hence if N is divided by p, the remainder is n. The rule given by Bachet corresponds to the case of a ’ = 3, b ’ = 4, c ’ = 5, p = 60, A = 40, B = 45, C = 36. If the number chosen is less than 420, we may take a ’ = 3, b ’ = 4, c ’ = 5, d ’ = 7, p = 420, A = 280, B = 105, C = 336, D = 120. To find the result of a series of operations performed on any number (unknown to the questioner) without asking any questions. All rules for solving such problems ultimately depend on so arranging the operations that the number disappears from the final result. Four examples will suffice. First Example* . Request some one to think of a number. Suppose it to be n. Ask him (i) to multiply it by any number you please (say) a; (ii) then to add (say) b; (iii) then to divide the sum by (say) c. (iv) Next, tell him to take a/c of the number originally chosen; and (v) to subtract this from the result of the third operation. The result of the first three operations is (na + b)/c, and the result of operation (iv) is na/c: the difference between these is b/c, and therefore is known to you. For example, if a = 6, b = 12, c = 4, and a/c = 1 1 2 , then the final result is 3. Second Example † . Ask A to take any number of counters that he pleases: suppose that he takes n counters. (i) Ask some one else, say B, to take p times as many, where p is any number you like to choose. (ii) Request A to give q of his counters to B, where q is any number you like to select. (iii) Next, ask B to transfer to A a number of counters equal to p times as many counters as A has in his possession. Then there will remain in B’s hands q(p+ 1) counters: this number is known to you; and the trick can be finished either by mentioning it or in any other way you like. The reason is as follows. The result of operation (ii) is that B has pn + q counters, and A has n − q counters. The result of (iii) is that B transfers p(n − q) counters to A: hence he has left in his possession (pn + q) − p(n − q) counters, that is, he has q(p + 1). For example, if originally A took any number of counters, then (if you chose p equal to 2), first you would ask B to take twice as many counters as A had done; next (if you chose q equal to 3) you would ask * Bachet, problem viii, p. 102. † Bachet, problem xiii, p. 123: Bachet presented the above trick in a somewhat more general form, but one which is less effective in practice. 8 ARITHMETICAL RECREATIONS. [CH. I A to give 3 counters to B; and then you would ask B to give to A a number of counters equal to twice the number then in A’s possession; after this was done you would know that B had 3(2 + 1), that is, 9 left. This trick (as also some of the following problems) may be performed equally

well with one person, in which case A may stand for his right hand and B for his left hand. Third Example. Ask some one to perform in succession the following operations. (i) Take any number of three digits. (ii) Form a new number by reversing the order of the digits. (iii) Find the difference of these two numbers. (iv) Form another number by reversing the order of the digits in this difference. (v) Add together the results of (iii) and (iv). Then the sum obtained as the result of this last operation will be 1089. An illustration and the explanation of the rule are given below. (i) 237 100a + 10b + c (ii) 732 100c + 10b + a (iii) 495 100(a − c − 1) + 90 + (10 + c − a) (iv) 594 100(10 + c − a) + 90 + (a − c − 1) (v) 1089 900 + 180 + 9 Fourth Example* . The following trick depends on the same principle. Ask some one to perform in succession the following operations. (i) To write down any sum of money less than £12; the number of pounds not being the same as the number of pence. (ii) To reverse this sum, that is, to write down a sum of money obtained from it by interchanging the numbers of pounds and pence. (iii) To find the difference between the results of (i) and (ii). (iv) To reverse this difference. (v) To add together the results of (iii) and (iv). Then this sum will be £12. 18s. 11d. * Educational Times Reprints, 1890, vol. liii, p. 78. CH. I] ELEMENTARY TRICKS AND PROBLEMS. 9 For instance, take the sum £10. 17s. 5d.; we have £. s. d. (i) . . . . . 10 17 5 (ii) . . . . . 5 17 10 (iii) . . . . . 4 19 7 (iv) . . . . . 7 19 4 (v) . . . . . 12 18 11 The following work explains the rule, and shows that the final result is independent of the sum written down initially. £. s. d. (i) . . . . . a b c (ii) . . . . . c b a (iii) . . . . . a − c − 1 19 c − a + 12 (iv) . . . . . c − a + 12 19 a − c − 1 (v) . . . . . 11 38 11 The rule can be generalized to cover any system of monetary units. Problems involving Two Numbers. I proceed next to give a couple of examples of a class of problems which involve two numbers. First Example* . Suppose that there are two numbers, one even and the other odd, and that a person A is asked to select one of them, and that another person B takes the other. It is desired to know whether A selected the even or the odd number. Ask A to multiply his number by 2 (or any even number) and B to multiply his by 3 (or any odd number). Request them to add the two products together and tell you the sum. If it is even, then originally A selected the odd number, but if it is odd, then originally A selected the even number. The reason is obvious. Second Example † . The above rule was extended by Bachet to any two numbers, provided they were prime to one another and one of them * Bachet, problem ix, p. 107. † Bachet, problem xi, p. 113. 10 ARITHMETICAL RECREATIONS. [CH. I was not itself a prime. Let the numbers be m and n, and suppose that n is exactly divisible by p. Ask A to select one of these numbers, and B to take the other. Choose a number prime to p, say q. Ask A to multiply his number by q, and B to multiply his number by p. Request them to add the products together and state the sum. Then A originally selected m or n, according as this result is not or is divisible by p. For example, m = 7, n = 15, p = 3, q = 2.

Problems depending on the Scale of Notation. Many of the rules for finding two or more numbers depend on the fact that in arithmetic an integral number is denoted by a succession of digits, where each digit represents the product of that digit and a power of ten, and the number is equal to the sum of these products. For example, 2017 signifies (2×103)+ (0×102)+ (1×10)+7; that is, the 2 represents 2 thousands, i.e. the product of 2 and 103 , the 0 represents 0 hundreds, i.e. the product of 0 and 102 ; the 1 represents 1 ten, i.e. the product of 1 and 10, and the 7 represents 7 units. Thus every digit has a local value. The application to tricks connected with numbers will be understood readily from three illustrative examples. First Example* . A common conjuring trick is to ask a boy among the audience to throw two dice, or to select at random from a box a domino on each half of which is a number. The boy is then told to recollect the two numbers thus obtained, to choose either of them, to multiply it by 5, to add 7 to the result, to double this result, and lastly to add to this the other number. From the number thus obtained, the conjurer subtracts 14, and obtains a number of two digits which are the two numbers chosen originally. For suppose that the boy selected the numbers a and b. Each of these is less than ten—dice or dominoes ensuring this. The successive operations give (i) 5a; (ii) 5a+7; (iii) 10a+14; (iv) 10a+14+b. Hence, if 14 is subtracted from the final result, there will be left a number of two digits, and these digits are the numbers selected originally. An analogous trick might be performed in other scales of notation if it was thought necessary to disguise the process further. * Some similar questions were given by Bachet in problem xii, p. 117; by Oughtred in his Mathematicall Recreations (translated from or founded on van Etten's work of 1633), London, 1653, problem xxxiv; and by Ozanam, part i, chapter x. CH. I] ELEMENTARY TRICKS AND PROBLEMS. 11 Second Example* . Similarly, if three numbers, say, a, b, c, are chosen, then, if each of them is less than ten, they can be found by the following rule. (i) Take one of the numbers, say, a, and multiply it by 2. (ii) Add 3 to the product; the result is 2a + 3. (iii) Multiply this by 5, and add 7 to the product; the result is 10a + 22. (iv) To this sum add the second number. (v) Multiply the result by 2. (vi) Add 3 to the product. (vii) Multiply by 5, and add the third number to the product. The result is 100a+ 10b+c+ 235. Hence, if the final result is known, it is sufficient to subtract 235 from it, and the remainder will be a number of three digits. These digits are the numbers chosen originally. I have seen a similar rule applied to determine the birthday and age of some one in the audience. The result is a number of six digits, of which the first two digits give the day of the month, the middle two digits the number of the month, and the last two digits the present age. Third Example† . The following rule for finding a man's age is of the same kind. Take the tens digit of the year of birth; (i) multiply it by 5; (ii) to the product add 2; (iii) multiply the result by 2; (iv) to this product add the units digit of the birth-year; (v) subtract the sum from 110. The result is the man's age in 1906. The algebraic

proof of the rule is obvious. Let a and b be the tens and units digits of the birth-year. The successive operations give (i) 5a; (ii) 5a + 2; (iii) 10a + 4 (iv) 10a + 4 + b; (v) 106 − (10a + b), which is his age in 1906. The rule can be easily adapted to give the age in any specified year. Other Problems with numbers in the denary scale. I may mention here two or three other slight problems dependent on the common scale of notation, which, as far as I am aware, are unknown to most compilers of books of puzzles. First Problem. The first of them is as follows. Take any number of three digits: reverse the order of the digits: subtract the number so formed from the original number: then, if the last digit of the difference is mentioned, all the digits in the difference are known. For let a be the hundreds digit of the number chosen, b be the tens digit, and c be the units digit. Therefore the number is 100a + 10b + c. The number obtained by reversing the digits is 100c + 10b + a. The * Bachet gave some similar questions in problem xii, p. 117. † A similar question was given by Laisant and Perrin in their Algèbre, Paris, 1892; and in L'Illustration for July 13, 1895. 12 ARITHMETICAL RECREATIONS. [CH. I difference of these numbers is equal to (100a+c)−(100c+a), that is, to 99(a − c). But a − c is not greater than 9, and therefore the remainder can only be 99, 198, 297, 396, 495, 594, 693, 792, or 891—in each case the middle digit being 9 and the digit before it (if any) being equal to the difference between 9 and the last digit. Hence, if the last digit is known, so is the whole of the remainder. Second Problem. The second problem is somewhat similar and is as follows. (i) Take any number; (ii) reverse the digits; (iii) find the difference between the number formed in (ii) and the given number; (iv) multiply this difference by any number you like to name; (v) cross out any digit except a nought; (vi) read the remainder. Then the sum of the digits in the remainder subtracted from the next highest multiple of nine will give the figure struck out. This follows at once from the fact that the result of operation (iii)— and therefore also of operation (iv)—is necessarily a multiple of nine, and it is known that the sum of the digits of every multiple of nine is itself a multiple of nine. Miscellaneous Questions. Besides these problems, properly so called, there are numerous questions on numbers which can be solved empirically, but which are of no special mathematical interest. As an instance I may quote a question which attracted some attention in London in 1893, and may be enunciated as follows. With the seven digits 9, 8, 7, 6, 5, 4, 0 express three numbers whose sum is 82: each digit, being used only once, and the use of the usual notations for fractions being allowed. One solution is $80.69 +\dot{} .74 +\dot{} .5\dot{}$. Similar questions are with the ten digits, 9, 8, 7, 6, 5, 4, 3, 2, 1, 0, to express numbers whose sum is unity; a solution is 35/70 and 148/296. If the sum were 100, a solution would be 50, 49, 1/2, and 38/76. A less straightforward question would be, with the nine digits, 9, 8, 7, 6, 5, 4, 3, 2, 1, to express four numbers whose sum is 100; a solution is 78, 15, √2 9, and √3 64. Problems with a series of things which are numbered. Any collection of things which can be distinguished one

from the other—especially if numbered consecutively—afford easy concrete illustrations of questions depending on these elementary properties of numbers. As examples I proceed to enumerate a few familiar tricks. The first two of these are commonly shown by the use of a watch, the last three are best exemplified by the use of a pack of playing CH. I] ELEMENTARY TRICKS AND PROBLEMS. 13 cards, which readily lend themselves to such illustrations, and I present them in these forms. First Example* . The first of these examples is connected with the hours marked on the face of a watch. In this puzzle some one is asked to think of some hour, say, m, and then to touch a number that marks another hour, say, n. Then if, beginning with the number touched, he taps each successive hour marked on the face of the watch, going in the opposite direction to that in which the hands of the watch move, and reckoning to himself the taps as m, (m + 1), &c., the (n + 12)th tap will be on the hour he thought of. For example, if he thinks of v and touches ix, then, if he taps successively ix, viii, vii, vi, . . . , going backwards and reckoning them respectively as 5, 6, 7, 8, . . . , the tap which he reckons as 21 will be on the v. The reason of the rule is obvious, for he arrives finally at the (n + 12 − m)th hour from which he started. Now, since he goes in the opposite direction to that in which the hands of the watch move, he has to go over (n − m) hours to reach the hour m: also it will make no difference if in addition he goes over 12 hours, since the only effect of this is to take him once completely round the circle. Now (n + 12 − m) is always positive, since m < 12, and therefore if we make him pass over (n + 12 − m) hours we can give the rule in a form which is equally valid whether m is greater or less than n. Second Example. The following is another well-known way of indicating on a watch-dial an hour selected by some one. I do not know who first invented it. If the hour is tapped by a pencil beginning at vii and proceeding backwards round the dial to vi, v, &c., and if the person who selected the number counts the taps, reckoning from the hour selected (thus, if he selected x, he would reckon the first tap as the 11th), then the 20th tap as reckoned by him will be on the hour chosen. For suppose he selected the nth hour. Then the 8th tap is on xii and is reckoned by him as the (n + 8)th. The tap which he reckons as (n + 9)th is on xi, and generally the tap which he reckons as (n + p)th is on the hour (20 − p). Hence, putting p − 20 − n, the tap which he reckons as 20th is on the hour n. Of course the hours indicated by the first seven taps are immaterial. * Bachet, problem xx, p. 155; Oughtred, Mathematicall Recreations, London, 1653, p. 28. 14 ARITHMETICAL RECREATIONS. [CH. I Extension. It is obvious that the same trick can be performed with any collection of m things, such as cards or dominoes, which are distinguishable one from the other, provided m < 20. For suppose the m things are arranged on a table in some numerical order, and the nth thing is selected by a spectator. Then the first (19 − m) taps are immaterial, the (20 − m)th tap must be on the mth thing and be reckoned by the spectator as the (n+ 20−m)th, the (20−m+ 1)th tap must be on the (m−1)th thing and be

reckoned as the (n+20−m+1)th, and finally the (20 − n)th tap will be on the nth thing and is reckoned as the 20th tap. Third Example. The following example rests on an extension of the method used in the last question; it is very simple, but I have never seen it previously described in print. Suppose that a pack of n cards is given to some one who is asked to select one out of the first m cards and to remember (but not to mention) what is its number from the top of the pack (say it is actually the xth card in the pack). Then take the pack, reverse the order of the top m cards (which can be easily effected by shuffling), and transfer y cards (where y < n − m) from the bottom to the top of the pack. The effect of this is that the card originally chosen is now the (y + m − x + 1)th from the top. Return to the spectator the pack so rearranged, and ask that the top card be counted as the (x + 1)th, the next as the (x + 2)th, and so on, in which case the card originally chosen will be the (y + m + 1)th. Now y and m can be chosen as we please, and may be varied every time the trick is performed; thus any one unskilled in arithmetic will not readily detect the modus operandi. Fourth Example* . Place a card on the table, and on it place as many other cards from the pack as with the number of pips on the card will make a total of twelve. For example, if the card placed first on the table is the five of clubs, then seven additional cards must be placed on it. The court cards may have any values assigned to them, but usually they are reckoned as tens. This is done again with another card, and thus another pile is formed. The operation may be repeated either only three or four times or as often as the pack will permit of such piles being formed. If finally there are p such piles, and if the number of cards left over is r, then the sum of the number of pips on the bottom cards of all the piles will be 13(p − 4) + r. * A particular case of this problem was given by Bachet, problem xvii, p. 138. CH. I] MEDIEVAL PROBLEMS IN ARITHMETIC. 15 For, if x is the number of pips on the bottom card of a pile, the number of cards in that pile will be 13 − x. A similar argument holds for each pile. Also there are 52 cards in the pack; and this must be equal to the sum of the cards in the p piles and the r cards left over. ∴ (13 − x1) + (13 − x2) + · · · + (13 − xp) + r = 52 , ∴ 13p − (x1 + x2 + · · · + xp) + r = 52 , ∴ x1 + x2 + · · · + xp = 13p − 52 + r = 13(p − 4) + r . More generally, if a pack of n cards is taken, and if in each pile the sum of the pips on the bottom card and the number of cards put on it is equal to m, then the sum of the pips on the bottom cards of the piles will be (m + 1)p + r − n. In an écarté pack n = 32, and it is convenient to take m = 15. Fifth Example. It may be noticed that cutting a pack of cards never alters the relative position of the cards provided that, if necessary, we regard the top card as following immediately after the bottom card in the pack. This is used in the following trick* . Take a pack, and deal the cards face upwards on the table, calling them one, two, three, &c. as you put them down, and noting in your own mind the card first dealt. Ask some one to select a card and recollect its number. Turn the pack over, and let it be cut (not shuffled) as often as you like. Enquire what was the

number of the card chosen. Then, if you deal, and as soon as you come to the original first card begin (silently) to count, reckoning this as one, the selected card will appear at the number mentioned. Of course, if all the cards are dealt before reaching this number, you must turn the cards over and go on counting continuously. Another similar trick is performed by handing the pack face upwards to some one, and asking him to select a card and state its number, reckoning from the top; suppose it to be the nth. Next, ask him to choose a number at which it shall appear in the pack; suppose he selects the mth. Take the pack and secretly move m−n cards from the bottom to the top (or if n is greater than m, then n − m from the top to the bottom) and of course the card will be in the required position. * Bachet, problem xix, p. 152. 16 ARITHMETICAL RECREATIONS. [CH. I Medieval Problems in Arithmetic. Before leaving the subject of these elementary questions, I may mention a few problems which for centuries have appeared in nearly every collection of mathematical recreations, and therefore may claim what is almost a prescriptive right to a place here. First Example* . The following is a sample of one class of these puzzles. Three men robbed a gentleman of a vase, containing 24 ounces of balsam. Whilst running away they met in a wood with a glass-seller, of whom in a great hurry they purchased three vessels. On reaching a place of safety they wished to divide the booty, but they found that their vessels contained 5, 11, and 13 ounces respectively. How could they divide the balsam into equal portions? Problems like this can be worked out only by trial: there are several solutions, of which one is as follows. The vessels can contain . . . . . 24 oz. 13 oz. 11 oz. 5 oz. Their contents originally are 24 . . . 0 . . . 0 . . . 0 . . . First, make their contents . . . 0 . . . 8 . . . 11 . . . 5 . . . Second, ” ” . . . 16 . . . 8 . . . 0 . . . 0 . . . Third, ” ” . . . 16 . . . 0 . . . 8 . . . 0 . . . Fourth, ” ” . . . 3 . . . 13 . . . 8 . . . 0 . . . Fifth, ” ” . . . 3 . . . 8 . . . 8 . . . 5 . . . Sixth, ” ” . . . 8 . . . 8 . . . 8 . . . 0 . . . Second Example† . The next of these is a not uncommon game, played by two people, say A and B. A begins by mentioning some number not greater than (say) six, B may add to that any number not greater than six, A may add to that again any number not greater than six, and so on. He wins who is the first to reach (say) 50. Obviously, if A calls 43, then whatever B adds to that, A can win next time. Similarly, if A calls 36, B cannot prevent A’s calling 43 the next time. In this way it is clear that the key numbers are those forming the arithmetical progression 43, 36, 29, 22, 15, 8, 1; and whoever plays first ought to win. Similarly, if no number greater than m may be added at any one time, and n is the number to be called by the victor, then the key num- * Some similar problems were given by Bachet, appendix, problem iii, p. 206; problem ix, p. 233; by Oughtred in his Recreations, p. 22: and by Ozanam, 1803 edition, vol. i, p. 174; 1840 edition, p. 79. Earlier instances occur in Tartaglia’s writings. † Bachet, problem xxii, p. 170. CH. I] MEDIEVAL PROBLEMS IN ARITHMETIC. 17 bers will be those forming the arithmetical progression whose common difference is m + 1 and whose smallest term is the remainder

obtained by dividing n by m + 1. The same game may be played in another form by placing n coins, matches, or other objects on a table, and directing each player in turn to take away not more than m of them. Whoever takes away the last coin wins. Obviously the key numbers are multiples of m + 1, and the first player who is able to leave an exact multiple of (m + 1) coins can win. Perhaps a better form of the game is to make that player lose who takes away the last coin, in which case each of the key numbers exceeds by unity a multiple of m + 1. Mr Loyd has also suggested* a modification which is equivalent to placing n counters in the form of a circle, and allowing each player in succession to take away not more than m of them which are in unbroken sequence: m being less than n and greater than unity. In this case the second of the two players can always win. Recent Extension of this Problem. The games last described are very simple, but if we impose on the original problem the additional restriction that each player may not add the same number more than three times, the analysis becomes by no means easy. It is difficult in this case to say whether it is an advantage to begin or not. I have never seen this extension described in print, and I will therefore enunciate it at length. Suppose that each player is given eighteen cards, three of them marked 6, three marked 5, three marked 4, three marked 3, three marked 2, and three marked 1. They play alternately; A begins by playing one of his cards; then B plays one of his, and so on. He wins who first plays a card which makes the sum of the points or numbers on all the cards played exactly equal to 50, but he loses if he plays a card which makes this sum exceed 50. The game can be played mentally or by noting the numbers on a piece of paper, and in practice it is unnecessary to use cards. Thus, if they play as follows A, 4; B, 3; A, 1; B, 6; A, 3; B, 4; A, 4; B, 5; A, 4; B, 4; A, 5; the game stands at 43. B can now win, for he may safely play 3, since A has not another 4 wherewith to follow it; and if A plays less than 4, B will win the next time. Again, if they play * Tit-Bits, London, July 17, Aug. 7, 1897. 18 ARITHMETICAL RECREATIONS. [CH. I thus, A, 6; B, 3; A, 1; B, 6; A, 3; B, 4; A, 2; B, 5; A, 1; B, 5; A, 2; B, 5; A, 2; B, 3; A is now forced to play 1, and B wins by playing 1. The game can be also played if each player is given only two cards of each kind. Third Example. The following medieval problem is somewhat more elaborate. Suppose that three people, P, Q, R, select three things, which we may denote by a, e, i, respectively, and that it is desired to find by whom each object was selected* . Place 24 counters on a table. Ask P to take one counter, Q to take two counters, and R to take three counters. Next, ask the person who selected a to take as many counters as he has already, whoever selected e to take twice as many counters as he has already, and whoever selected i to take four times as many counters as he has already. Note how many counters remain on the table. There are only six ways of distributing the three things among P, Q, and R; and the number of counters remaining on the table is different for each way. The remainders may be 1, 2, 3, 5, 6, or 7. Bachet summed up the

results in the mnemonic line Par fer (1) César (2) jadis (3) devint (5) si grand (6) prince (7). Corresponding to any remainder is a word or words containing two syllables: for instance, to the remainder 5 corresponds the word devint. The vowel in the first syllable indicates the thing selected by P, the vowel in the second syllable indicates the thing selected by Q, and of course R selected the remaining thing. Salve certa animae semita vita quies was suggested by Oughtred† as an alternative mnemonic line. Extension. M. Bourlet, in the course of a very kindly notice‡ of the second edition of this work, has given a much neater solution of the above question, and has extended the problem to the case of n people, P0, P1, P2, . . . , Pn−1, each of whom selects one object, out of a collection of n objects, such as dominoes or cards. It is required to know which domino or card was selected by each person. Let us suppose the dominoes to be denoted or marked by the numbers 0, 1, . . . , n − 1, instead of by vowels. Give one counter to P1, two counters to P2, and generally k counters to Pk. Note the number of counters left on the table. Next ask the person who had chosen the * Bachet, problem xxv, p. 187. † Mathematicall Recreations, London, 1653, p. 20. ‡ Bulletin des sciences mathématiques, Paris, 1893, vol. xvii, pp. 105–107. CH. I] MEDIEVAL PROBLEMS IN ARITHMETIC. 19 domino 0 to take as many counters as he had already, and generally whoever had chosen the domino h to take n h times as many dominoes as he had already: thus if Pk had chosen the domino numbered h, he would take n hk counters. Note the total number of counters taken, i.e. P n hk. Divide it by n, then the remainder will be the number on the domino selected by P0; divide the quotient by n, and the remainder will be the number on the domino selected by P1; divide this quotient by n, and the remainder will be the number on the domino selected by P2; and so on. In other words, if the number of counters taken is expressed in the scale of notation whose radix is n, then the (h + 1)th digit from the right will give the number on the domino selected by Ph. Thus in Bachet's problem with 3 people and 3 dominoes, we should first give one counter to Q, and two counters to R, while P would have no counters; then we should ask the person who selected the domino marked 0 or a to take as many counters as he had already, whoever selected the domino marked 1 or e to take three times as many counters as he had already, and whoever selected the domino marked 2 or i to take nine times as many counters as he had already. By noticing the original number of counters, and observing that 3 of these had been given to Q and R, we should know the total number taken by P, Q, and R. If this number were divided by 3, the remainder would be the number of the domino chosen by P; if the quotient were divided by 3 the remainder would be the number of the domino chosen by Q; and the final quotient would be the number of the domino chosen by R. I may add that Bachet also discussed the case when n = 4, which had been previously considered by Diego Palomino in 1599, but as M. Bourlet's method is general, it is unnecessary to discuss further particular

cases. Decimation. The last of these antique problems to which I referred consists in placing men round a circle so that if every nth man is killed the remainder shall be certain specified individuals. When decimation was a not uncommon punishment a knowledge of this kind may have had practical interest. Hegesippus* says that Josephus saved his life by such a device. According to his account, after the Romans had captured Jotopat, Josephus and forty other Jews took refuge in a cave. Josephus, much to his disgust, found that all except himself and one other man were resolved * De Bello Judaico, bk. iii, chaps. 16–18. 20 ARITHMETICAL RECREATIONS. [CH. I to kill themselves, so as not to fall into the hands of their conquerors. Fearing to show his opposition too openly he consented, but declared that the operation must be carried out in an orderly way, and suggested that they should arrange themselves round a circle and that every third person should be killed until but one man was left, who must then commit suicide. It is alleged that he placed himself and the other man in the 31st and 16th place respectively, with a result which will be easily foreseen. The question is usually presented in the following form. A ship, carrying as passengers fifteen Turks and fifteen Christians, encountered a storm, and the pilot declared that, in order to save the ship and crew, one-half of the passengers must be thrown into the sea. To choose the victims the passengers were placed round a circle, and it was agreed that every ninth man should be cast overboard, reckoning from a certain point. It is desired to find an arrangement by which all the Christians should be saved.* Problems like this can be easily solved by counting, but it is impossible to give a general rule. In this case, the Christians, reckoning from the man first counted, must occupy the places 1, 2, 3, 4, 10, 11, 13, 14, 15, 17, 20, 21, 25, 28, 29. This arrangement can be recollected by the positions of the vowels in the following doggerel rhyme, From numbers' aid and art, never will fame depart, where a stands for 1, e for 2, i for 3, o for 4, and u for 5. Hence (looking only at the vowels in the verse) the order is 4 Christians, 5 Turks, 2 Christians, 1 Turk, 3 Christians, 1 Turk, 1 Christian, 2 Turks, 2 Christians, 3 Turks, 1 Christian, 2 Turks, 2 Christians, 1 Turk. Other similar mnemonic lines in French and in Latin were given by Bachet and by Ozanam respectively. Arithmetical Fallacies. I insert next some instances of demonstrations† leading to arithmetical results which are obviously * Bachet, problem xxiii, p. 174. The same problem had been previously enunciated by Tartaglia. † Of the fallacies given in the text, the first, second, and third, are well known; the fourth is not new, but the earliest work in which I recollect seeing it is my Algebra, Cambridge, 1890, p. 430; the fifth is given in G.C. Chrystal's Algebra, CH. I] ARITHMETICAL FALLACIES. 21 impossible. I include algebraical proofs as well as arithmetical ones. The fallacies are so patent that in preparing the first and second editions I did not think such questions worth printing, but, as some correspondents have expressed a contrary opinion, I give them for what they are worth. First fallacy. One of the oldest of

these—and not a very interesting specimen—is as follows. Suppose that a = b, then ab = a 2 . ∴ ab − b 2 = a 2 − b 2 . ∴ b(a − b) = (a + b)(a − b). ∴ b = a + b . ∴ b = 2b . ∴ 1 = 2 . Second Fallacy. Another instance, almost as puerile, is as follows. Let a and b be two unequal numbers, and let c be their arithmetic mean, hence a + b = 2c . ∴ (a + b)(a − b) = 2c(a − b). ∴ a 2 − 2ac = b 2 − 2bc . ∴ a 2 − 2ac + c 2 = b 2 − 2bc + c 2 . ∴ (a − c) 2 = (b − c) 2 . ∴ a = b . Edinburgh, 1889, vol. ii, p. 159; the eighth is due to G.T. Walker, and, as far as I know, has not appeared in any other book; the ninth is due to D'Alembert; and the tenth to F. Galton. A mechanical demonstration that 1 = 2 was given by R. Chartres in Knowledge, July, 1891. J.L.F. Bertrand pointed out that a demonstration that 1 = −1 can be also obtained from the proposition in the Integral Calculus that, if the limits are constant, the order of integration is indifferent; hence the integral to x (from x = 0 to x = 1) of the integral to y (from y = 0 to y = 1) of a function ϕ should be equal to the integral to y (from y = 0 to y = 1) of the integral to x (from x = 0 to x = 1) of ϕ, but if ϕ = (x 2 − y 2)/(x 2 + y 2) 2 , this gives 1 4 π = − 1 4 π. 22 ARITHMETICAL RECREATIONS. [CH. I Third Fallacy. Another example, the idea of which is due to John Bernoulli, may be stated as follows. We have (−1)2 = 1 . Take logarithms, ∴ 2 log(−1) = log 1 = 0 . ∴ log(−1) = 0 . ∴ −1 = e 0 . ∴ −1 = 1 . The same argument may be expressed thus. Let x be a quantity which satisfies the equation e x = −1 . Square both sides, ∴ e 2x = 1 . ∴ 2x = 0 . ∴ x = 0 . ∴ e x = e 0 . But e x = −1 and e 0 = 1, ∴ −1 = 1 . Fourth Fallacy. As yet another instance, we know that log(1 + x) = x − 1 2 x 2 + 1 3 x 3 − · · · . If x = 1, the resulting series is convergent; hence we have log 2 = 1 − 1 2 + 1 3 − 1 4 + 1 5 − 1 6 + 1 7 − 1 8 + 1 9 − · · · . ∴ 2 log 2 = 2 − 1 + 2 3 − 1 2 + 2 5 − 1 3 + 2 7 − 1 4 + 2 9 − · · · . Taking those terms together which have a common denominator, we obtain 2 log 2 = 1 + 1 3 − 1 2 + 1 5 + 1 7 − 1 4 + 1 9 − · · · = 1 − 1 2 + 1 3 − 1 4 + 1 5 − · · · = log 2 . Hence 2 = 1 . CH. I] ARITHMETICAL FALLACIES. 23 Fifth Fallacy. This fallacy is very similar to that last given. We have log 2 = 1 − 1 2 + 1 3 − 1 4 + 1 5 − 1 6 + · · · = 1 + 1 3 + 1 5 + · · · − 1 2 + 1 4 + 1 6 + · · · = 1 + 1 3 + 1 5 + · · · + 1 2 + 1 4 + 1 6 + · · · − 2 1 2 + 1 4 + 1 6 + · · · = 1 + 1 2 + 1 3 + · · · − 1 + 1 2 + 1 3 + · · · = 0 . The error in each of the foregoing examples is obvious, but the fallacies in the next examples are concealed somewhat better. Sixth Fallacy. We can write the identity √ −1 = √ −1 in the form r −1 1 = r 1 −1 , hence √ −1 √ 1 = √ 1 √ −1 , therefore (√ −1)2 = (√ 1)2 , that is, −1 = 1 . Seventh Fallacy. Again, we have √ a × √ b = √ ab . Hence √ −1 × √ −1 = p (−1)(−1), therefore (√ −1)2 = √ 1 , that is, −1 = 1 . Eighth Fallacy. The following demonstration depends on the fact that an algebraical identity is true whatever be the symbols used in it, and it will appeal only to those who are familiar with this fact. We have, as an identity, √ x − y = i √ y − x . . . . . (i), where i stands either for + √ −1 or for − √ −1. Now an identity in x and y is necessarily true whatever numbers x and y may represent. First put x = a and y = b, ∴ √ a − b = i √ b − a . . . . . (ii). 24 ARITHMETICAL RECREATIONS. [CH. I Next put x = b and y = a, ∴ √ b − a = i √ a − b . . . . . (iii). Also since (i)

is an identity, it follows that in (ii) and (iii) the symbol i must be the same, that is, it represents + √ −1 or − √ −1 in both cases. Hence, from (ii) and (iii), we have √ a − b √ b − a = i 2 √ b − a √ a − b , ∴ 1 = i 2 , that is 1 = −1 . Ninth Fallacy. The following fallacy is due to D'Alembert* . We know that if the product of two numbers is equal to the product of two other numbers, the numbers will be in proportion, and from the definition of a proportion it follows that if the first term is greater than the second, then the third term will be greater than the fourth: thus, if ad = bc, then a : b = c : d, and if in this proportion a > b, then c > d. Now if we put a = d = 1 and b = c = −1 we have four numbers which satisfy the relation ad = bc and such that a > b; hence, by the proposition, c > d, that is, −1 > 1, which is absurd. Tenth Fallacy. The mathematical theory of probability leads to various paradoxes: of these one specimen† will suffice. Suppose three coins to be thrown up and the fact whether each comes down head or tail to be noticed. The probability that all three coins come down head is clearly (1 2) 3 , that is, is 1 8 ; similarly the probability that all three come down tail is 1 8 : hence the probability that all the coins come down alike (i.e. either all of them heads or all of them tails) is 1 4 . But, of three coins thus thrown up, at least two must come down alike; now the probability that the third coin comes down head is 1 2 and the probability that it comes down tail is 1 2 , thus the probability that it comes down the same as the other two coins is 1 2 : hence the probability that all the coins come down alike is 1 2 . I leave to my readers to say whether either of these conflicting conclusions is right and if so, which. Arithmetical Problems. To the above examples I may add the following questions, which I have often propounded in past years: though not fallacies, they may serve to illustrate the fact that the answer to * Opuscules mathématiques, Paris, 1761, vol. i, p. 201. † See Nature, Feb. 15, March 1, 1894, vol. xlix, pp. 365–366, 413. CH. I] ARITHMETICAL FALLACIES. 25 an arithmetical question is frequently different to what a hasty reader might suppose. The first of these questions is as follows. Two clerks are engaged, one at a salary commencing at the rate of (say) £100 a year with a rise of £20 every year, the other at a salary commencing at the same rate (£100 a year) with a rise of £5 every half-year, in each case payments being made half-yearly: which has the larger income? The answer is the latter; for in the first year the first clerk receives £100, but the second clerk receives £50 and £55 as his two half-yearly payments and thus receives in all £105. In the second year the first clerk receives £120, but the second clerk receives £60 and £65 as his two half-yearly payments and thus receives in all £125. In fact the second clerk will always receive £5 a year more than the first clerk. As another question take the following. A man bets 1/nth of his money on an even chance (say tossing heads or tails with a penny): he repeats this again and again, each time betting 1/nth of all the money then in his possession. If, finally, the number of times he has won is equal to the number of times he has lost, has he gained or lost by the transaction?

He has, in fact, lost. Here is another simple question to which not unfrequently I have received incorrect answers. One tumbler is half-full of wine, another is half-full of water: from the first tumbler a teaspoonful of wine is taken out and poured into the tumbler containing the water: a teaspoonful of the mixture in the second tumbler is then transferred to the first tumbler. As the result of this double transaction, is the quantity of wine removed from the first tumbler greater or less than the quantity of water removed from the second tumbler? Nineteen people out of twenty will say it is greater, but this is not the case. Routes on a Chess-Board. A not uncommon problem can be generalised as follows* . Construct a rectangular board of mn cells (or small squares) by ruling m + 1 vertical lines and n + 1 horizontal lines. It is required to know how many routes can be taken from the top left-hand corner to the bottom right-hand corner, the motion being along the ruled lines and its direction being always either vertically downwards or horizontally from left to right. The answer is (m+n)!/m!n!: thus on a square board containing 16 cells (i.e. one-quarter of a chess-board), * The substance of the problem was given in a scholarship paper set at Cambridge about 30 years ago, and possibly was not new then. 26 ARITHMETICAL RECREATIONS. [CH. I where m = n = 4, there are 70 such routes; while on a common chessboard, where m = n = 8, there are no less than 12870 such routes. A similar theorem can be enunciated for a parallelopiped. Another problem of a somewhat similar type is the determination of the number of closed routes through mn points arranged in m rows and n columns, following the lines of the quadrilateral net-work, and passing once and only once through each point* . Permutation Problems. As other simple illustrations of the very large number of ways in which combinations of even a few things can be arranged, I may note that as many as 19, 958400 distinct skeleton cubes can be formed with twelve differently coloured rods of equal length† ; again there are 3, 979614, 965760 ways of arranging a set of twenty-eight dominoes (i.e. a set from double zero to double six) in a line, with like numbers in contact‡ ; while there are no less than 53644, 737765, 488792, 839237, 440000 possible different distributions of hands at whist with a pack of fifty-two cards§ . Voting Problems. Here is a simple example on combinations dealing with the cumulative vote as affecting the representation of a minority. If there are p electors each having r votes of which not more than s may be given to one candidate, and n men are to be elected, then the least number of supporters who can secure the election of a candidate must exceed pr/(ns + r). Exploration Problems. Another common question is concerned with the maximum distance into a desert which could be reached from a frontier settlement by the aid of a party of n explorers, each capable of carrying provisions that would last one man for a days. The answer is that the man who reaches the greatest distance will occupy na/(n + 1) days before he returns to his starting point. If in the course of their journey they may make depôts, the longest

possible journey will occupy 1 2 a(1 + 1 2 + 1 3 + · · · + 1/n) days. Further extensions by the use of horses and cycles will suggest themselves. Here I conclude my account of such of these easy problems on * See C.F. Sainte-Marie in L'Intermédiaire des mathématiciens, Paris, vol. xi, March, 1904, pp. 86–88. † Mathematical Tripos, Cambridge, Part I, 1894. ‡ Reiss in Annali di matematica, Milan, November, 1871, vol. v, pp. 63–120. § That is (52!)/(13!)4 . CH. I] BACHET'S WEIGHTS PROBLEM. 27 numbers or elementary algebra as seemed worth reproducing. It will be noticed that the majority of them either are due to Bachet or were collected by him in his classical Problèmes; but it should be added that besides the questions I have mentioned he enunciated, even if he did not always solve, some other problems of greater interest. One instance will suffice. Bachet's Weights Problem* . Among the more difficult problems proposed by Bachet was the determination of the least number of weights which would serve to weigh any integral number of pounds from 1 lb. to 40 lbs. inclusive. Bachet gave two solutions: namely, (i) the series of weights of 1, 2, 4, 8, 16, and 32 lbs.; (ii) the series of weights of 1, 3, 9, and 27 lbs. If the weights may be placed in only one of the scale-pans, the first series gives a solution, as had been pointed out in 1556 by Tartaglia† . Bachet, however, assumed that any weight might be placed in either of the scale-pans. In this case the second series gives the least possible number of weights required. His reasoning is as follows. To weigh 1 lb. we must have a 1 lb. weight. To weigh 2 lbs. we must have in addition either a 2 lb. weight or a 3 lb. weight; but, if we are confined to only one new weight (in addition to the 1 lb. we have got already), then with no weight greater than 3 lbs. could we weigh 2 lbs.: if we use a 2 lb. weight we then can weigh 1 lb., 2 lbs., and 3 lbs., but if we use a 3 lb. weight we then can weigh 1 lb., (3 − 1) lbs., 3 lbs., and (3 + 1) lbs.; hence a 3 lb. weight is preferable. Similarly, to enable us to weigh 5 lbs. we must have another weight not greater than 9 lbs., and a weight of 9 lbs. enables us to weigh every weight from 1 lb. to 13 lbs.; hence it is the best to choose. The next weight required will be 2(1+3+9)+1 lb., that is, will be 27 lbs.; and this enables us to weigh from 1 lb. to 40 lbs. Thus only four weights are required, namely, 1 lb., 3 lbs., 3 2 lbs., and 3 3 lbs. We can show similarly that the series of weights of 1, 3, 3 2 , . . . , 3 n−1 lbs. will enable us to weigh any integral number of pounds from 1 lb. to (1 + 3 + 32 + · · · 3 n−1) lbs., that is, to 1 2 (3n − 1) lbs. This is the least number with which the problem can be effected. To determine the arrangement of the weights to weigh any given mass we have only to express the number of pounds in it as a number in the ternary scale of notation, except that in finding the successive * Bachet, Appendix, problem v, p. 215. † Trattato de' numeri e misure, Venice, 1556, vol. ii, bk. i, chap. xvi, art. 32. 28 ARITHMETICAL RECREATIONS. [CH. I digits we must make every remainder either 0, 1, or −1: to effect this a remainder 2 must be written as 3 − 1, that is, the quotient must be increased by unity, in which case the remainder is −1. This is explained in most text-books on algebra.

Bachet's argument does not prove that his result is unique or that it gives the least possible number of weights required. These omissions have been supplied by Major MacMahon, who has discussed the far more difficult problem (of which Bachet's is a particular case) of the determination of all possible sets of weights, not necessarily unequal, which enable us to weigh any integral number of pounds from 1 to n inclusive, (i) when the weights may be placed in only one scale-pan, and (ii) when any weight may be placed in either scale-pan. He has investigated also the modifications of the results which are necessary when we impose either or both of the further conditions (a) that no other weighings are to be possible, and (b) that each weighing is to be possible in only one way, that is, is to be unique* . The method for case (i) consists in resolving 1 + x + x 2 + · · · + x n into factors, each factor being of the form 1 + x a + x 2a + · · · + x ma; the number of solutions depends on the composite character of n + 1. The method for case (ii) consists in resolving the expression x −n+x −n+1+· · · + x −1 + 1 + x + · · · + x n−1 + x n into factors, each factor being of the form x −ma + · · · + x −a + 1 + x a + · · · + x ma; the number of solutions depends on the composite character of 2n + 1. Bachet's problem falls under case (ii), n = 40. MacMahon's analysis shows that there are eight such ways of factorizing x −40 + x −39 + · · · + 1 + x 39 + x 40. First, there is the expression itself in which a = 1, m = 40. Second, the expression is equal to (1 − x 81)/x40(1 − x), which can be resolved into the product of (1 − x 3)/x(1 − x) and (1 − x 81)/x39(1 − x 3); hence it can be resolved into two factors of the form given above, in one of which a = 1, m = 1, and in the other, a = 3, m = 13. Third, similarly, it can be resolved into two such factors, in one of which a = 1, m = 4, and in the other a = 9, m = 4. Fourth, it can be resolved into three such factors, in one of which a = 1, m = 1, in another a = 3, m = 1, and in the other, a = 9, m = 4. Fifth, it can be resolved into two such factors, in one of which a = 1, m = 13, * See his article in the Quarterly Journal of Mathematics, 1886, vol. xxi, pp. 367–373. An account of the method is given in Nature, Dec. 4, 1890, vol. xlii, pp. 113–114. CH. I] PROBLEMS IN HIGHER ARITHMETIC. 29 and in the other a = 27, m = 1. Sixth, it can be resolved into three such factors, in one of which a = 1, m = 1, in another a = 3, m = 4, and in the other a = 27, m = 1. Seventh, it can be resolved into three such factors, in one of which a = 1, m = 4, in another a = 9, m = 1, and in the other a = 27, m = 1. Eighth, it can be resolved into four such factors, in one of which a = 1, m = 1, in another a = 3, m = 1, in another a = 9, m = 1, and in the other a = 27, m = 1. These results show that there are eight possible sets of weights with which any integral number of pounds from 1 to 40 can be weighed subject to the conditions (ii), (a), and (b). If we denote p weights each equal to w by w p , these eight solutions are 1 40; 1, 3 13; 1 4 , 9 4 ; 1, 3, 9 4 ; 1 13 , 27; 1, 3 4 , 27; 1 4 , 9, 27; 1, 3, 9, 27. The last of these is Bachet's solution: not only is it that in which the least number of weights are employed, but it is also the only unique one in which all the weights are unequal. Problems in Higher Arithmetic. At the

commencement of this chapter I alluded to the special interest which many mathematicians find in the theorems of higher arithmetic: such, for example, as that every prime of the form 4n + 1 and every power of it is expressible as the sum of two squares* , and the first and second powers can be expressed thus in only one way. For instance, 13 = 32 + 22 , 132 = 122 + 52 , 133 = 462 + 92 , and so on. Similarly 41 = 52 + 42 , 412 = 402 + 92 , 413 = 2362 + 1152 , and so on. Propositions such as the one just quoted may be found in textbooks on the theory of numbers and therefore lie outside the limits of this work, but there are one or two questions in higher arithmetic involving points not yet quite cleared up which may find a place here. Primes. The first of these is concerned with the possibility of determining readily whether a given number is prime or not. Euler and Gauss attached great importance to this problem, but failed to establish any conclusive test. It would seem, however, that Fermat possessed some means of finding from its form whether a given number (at any rate if one of certain known forms) was prime or not. Thus, in answer to Mersenne who asked if he could tell without much trouble whether the number 100895, 598169 was a prime, Fermat wrote on April 7, 1643, that it was the product of 898423 and 112303, both of which were * Fermat's Diophantus, Toulouse, 1670, bk. iii, prop. 22, p. 127; or Brassinne's Précis, Paris, 1853, p. 65. 30 ARITHMETICAL RECREATIONS. [CH. I primes. I have indicated elsewhere one way by which this result can be found, and Mr F.W. Laurence has indicated another which may have been that used by Fermat in this particular case. Mersenne's Numbers* . Another illustration, confirmatory of the opinion that Fermat or some of his contemporaries had a test by which it was possible to find out whether certain numbers were prime, may be drawn from Mersenne's Cogitata Physico-Mathematica which was published in 1644. In the preface to that work it is asserted that in order that 2 p − 1 may be prime, the only values of p, not greater than 257, which are possible are 1, 2, 3, 5, 7, 13, 17, 19, 31, 67, 127, and 257: I conjecture that the number 67 is a misprint for 61. With this correction the statement appears to be true, and it has been verified for all except nineteen values of p: namely, 71, 101, 103, 107, 109, 137, 139, 149, 157, 163, 167, 173, 181, 193, 199, 227, 229, 241, and 257. Of these values, Mersenne asserted that p = 257 makes 2 p − 1 a prime, and that the other values make 2 p − 1 a composite number. The demonstrations for the cases when p = 89, 127 have not been published; nor have the actual factors of 2 p − 1 when p = 89 been as yet determined: the discovery of these factors may be commended to those interested in the theory of numbers. Mersenne's result could not be obtained empirically, and it is impossible to suppose that it was worked out for every case; hence it would seem that whoever first enunciated it was acquainted with certain theorems in higher arithmetic which have not been re-discovered. Perfect Numbers† . The theory of perfect numbers depends directly on that of Mersenne's Numbers. A number is said to be perfect if it is

equal to the sum of all its integral subdivisors. Thus the subdivisors of 6 are 1, 2, and 3; the sum of these is equal to 6; hence 6 is a perfect number. It is probable that all perfect numbers are included in the formula 2 p−1 (2p − 1), where 2 p − 1 is a prime. Euclid proved that any number of this form is perfect; Euler showed that the formula includes all even perfect numbers; and there is reason to believe—though a rigid demonstration is wanting—that an odd number cannot be perfect. If * For references, see chapter ix below. † On the theory of perfect numbers, see bibliographical references by H. Brocard, L'Intermédiaire des mathématiciens, Paris, 1895, vol. ii, pp. 52–54; and 1905, vol. xii, p. 19. CH. I] GOLDBACH'S THEOREM. 31 we assume that the last of these statements is true, then every perfect number is of the above form. It is easy to establish that every number included in this formula (except when p = 2) is congruent to unity to the modulus 9, that is, when divided by 9 leaves a remainder 1; also that either the last digit is a 6 or the last two digits are 28. Thus, if p = 2, 3, 5, 7, 13, 17, 19, 31, 61, then by Mersenne's rule the corresponding values of 2 p − 1 are prime; they are 3, 7, 31, 127, 8191, 131071, 524287, 2147483647, 2305843009213693951; and the corresponding perfect numbers are 6, 28, 496, 8128, 33550336, 8589869056, 137438691328, 2305843008139952128, and 2658455991569831744654692615953842176. Goldbach's Theorem. Another interesting problem in higher arithmetic is the question whether there are any even integers which cannot be expressed as a sum of two primes. Probably there are none. The expression of all even1 integers not greater than 5000 in the form of a sum of two primes has been effected* , but a general demonstration that all even integers can be so expressed is wanting. Lagrange's Theorem† . Another theorem in higher arithmetic which, as far as I know, is still unsolved, is to the effect that every prime of the form 4n−1 is the sum of a prime of the form 4n+ 1 and of double a prime of the form 4n + 1; for example, 23 = 13 + 2 × 5. Lagrange, however, added that it was only by induction that he arrived at the result. Fermat's Theorem on Binary Powers. Fermat enriched mathematics with a multitude of new propositions. With two exceptions all these have been proved subsequently to be true. The first of these exceptions is his theorem on binary powers, in which he asserted that all numbers of the form 2 m + 1, where m = 2n , are primes‡ , but he added that, though he was convinced of the truth of this proposition, he could not obtain a valid demonstration. * Transactions of the Halle Academy (Naturforschung), vol. lxxii, Halle, 1897, pp. 5–214: see also L'Intermédiaire des mathématiciens, 1903, vol. x, and 1904, vol. xi. † Nouveaux Mémoires de l'Académie Royale des Sciences, Berlin, 1775, p. 356. ‡ Letter of Oct. 18, 1640, Opera, Toulouse, 1679, p. 162: or Brassinne's Précis, p. 143. 1. 'even' inserted as per errata sheet 32 ARITHMETICAL RECREATIONS. [CH. I It may be shown that 2 m + 1 is composite if m is not a power of 2, but of course it does not follow that 2 m + 1 is a prime if m is a power of 2. As a matter of fact the

theorem is not true. In 1732 Euler* showed that if n = 5 the formula gives 4294, 967297, which is equal to 641×6, 700417: curiously enough, these factors can be deduced at once from Fermat's remark on the possible factors of numbers of the form 2 m ± 1, from which it may be shown that the prime factors (if any) of 2 32 + 1 must be primes of the form 64n + 1. During the last thirty years it has been shown† that the resulting numbers are composite when n = 6, 9, 11, 12, 18, 23, 36, and 38: the two last numbers contain many thousands of millions of digits. I believe that Eisenstein asserted that the number of primes of the form 2 m + 1, where m = 2n , is infinite: the proof has not been published, but perhaps it might throw some light on the general theory. Fermat's Last Theorem. I pass now to the only other assertion made by Fermat which has not been proved hitherto. This, which is sometimes known as Fermat's Last Theorem, is to the effect‡ that no integral values of x, y, z can be found to satisfy the equation x n+y n = z n , if n is an integer greater than 2. This proposition has acquired extraordinary celebrity from the fact that no general demonstration of it has been given, but there is no reason to doubt that it is true. Fermat seems to have discovered its truth first§ for the case n = 3, and then for the case n = 4. His proof for the former of these cases is lost, but that for the latter is extant‖ , and a similar proof for the case of n = 3 was given by Euler¶ . These proofs depend upon showing that, if three integral values of x, y, z can be found which satisfy the equation, * Commentarii Academiae Scientiarum Petropolitanae, St Petersburg, 1738, vol. vi, p. 104; see also Novi Comm. CH. I] FERMAT'S LAST THEOREM. 33 then it will be possible to find three other and smaller integers which also satisfy it: in this way finally we show that the equation must be satisfied by three values which obviously do not satisfy it. Thus no integral solution is possible. It would seem that this method is inapplicable except when n = 3 and n = 4. Fermat's discovery of the general theorem was made later. An easy demonstration can be given on the assumption that every number can be resolved into prime (complex) factors in one and only one way. That assumption has been made by some writers, but it is not universally true. It is possible that Fermat made some such supposition, though it is perhaps more probable that he discovered a rigorous

demonstration. At any rate he asserts definitely that he had a valid proof— demonstratio mirabilis sane—and the fact that every other theorem on the subject which he stated he had proved has been subsequently verified must weigh strongly in his favour; especially as in making the one statement in his writings which is not correct he was scrupulously careful to add that he could not obtain a satisfactory demonstration of it. It must be remembered that Fermat was a mathematician of quite the first rank who had made a special study of the theory of numbers. That subject is in itself one of peculiar interest and elegance, but its conclusions have little practical importance, and since his time it has been discussed by only a few mathematicians, while even of them not many have made it their chief study. This is the explanation of the fact that it took more than a century before some of the simpler results which Fermat had enunciated were proved, and thus it is not surprising that a proof of the theorem which he succeeded in establishing only towards the close of his life should involve great difficulties. In 1823 Legendre* obtained a proof for the case of n = 5; in 1832 Lejeune Dirichlet† gave one for n = 14, and in 1840 Lamé and Lebesgue‡ gave proofs for n = 7. The proposition appears to be true universally, and in 1849 Kummer§ , by means of ideal primes, proved it to be so for all numbers except those (if any) which satisfy three conditions. It is not known * Reprinted in his Théorie des Nombres, Paris, 1830, vol. ii, pp. 361–368: see also pp. 5, 6. † Crelle's Journal, 1832, vol. ix, pp. 390–393. ‡ Liouville's Journal, 1841, vol. v, pp. 195–215, 276–9, 348–9. § References to Kummer's Memoirs are given in Smith's Report to the British Association on the Theory of Numbers, London, 1860. 34 ARITHMETICAL RECREATIONS. [CH. I whether any number can be found to satisfy these conditions, but it seems unlikely, and it has been shown that there is no number less than 100 which does so. The proof is complicated and difficult, and there can be little doubt is based on considerations unknown to Fermat. I may add that to prove the truth of the proposition when n is greater than 4, it obviously is sufficient to confine ourselves to cases where n is a prime, and the first step in Kummer's demonstration is to show that in such cases one of the numbers x, y, z must be divisible by n. Naturally there has been much speculation as to how Fermat arrived at the result. The modern treatment of higher arithmetic is founded on the special notation and processes introduced by Gauss, who pointed out that the theory of discrete magnitude is essentially different from that of continuous magnitude, but until the end of the last century the theory of numbers was treated as a branch of algebra, and such proofs by Fermat as are extant involve nothing more than elementary geometry and algebra, and indeed some of his arguments do not involve any symbols. This has led some writers to think that Fermat used none but elementary algebraic methods. This may be so, but the following remark, which I believe is not generally known, rather points to the opposite conclusion. He had proposed, as a problem to the English mathematicians, to show that there was only

one integral solution of the equation x 2 + 2 = y 3 : the solution evidently being x = 5, y = 3. On this he has a note* to the effect that there was no difficulty in finding a solution in rational fractions, but that he had discovered an entirely new method—sane pulcherrima et subtilissima—which enabled him to solve such questions in integers. It was his intention to write a work† on his researches in the theory of numbers, but it was never completed, and we know but little of his methods of analysis. I venture however to add my private suspicion that continued fractions played a not unimportant part in his researches, and as strengthening this conjecture I may note that some of his more recondite results—such as the theorem that a prime of the form 4n+ 1 is expressible as the sum of two squares—may be established with comparative ease by properties of such fractions. * Fermat's Diophantus, bk. vi, prop. 19, p. 320; or Brassinne's Précis, p. 122. † Fermat's Diophantus, bk. iv, prop. 31, p. 181; or Brassinne's Précis, p. 82. CHAPTER II. SOME GEOMETRICAL QUESTIONS. In this chapter I propose to enumerate certain geometrical questions the discussion of which will not involve necessarily any considerable use of algebra or arithmetic. Unluckily no writer like Bachet has collected and classified problems of this kind, and I take the following instances from my note-books with the feeling that they represent the subject but imperfectly. The first part of the chapter is devoted to questions which are of the nature of formal propositions: the last part contains a description of various trivial puzzles and games, which the older writers would have termed geometrical, but which the reader of to-day may omit without loss. In accordance with the rule I laid down for myself in the preface, I exclude the detailed discussion of theorems which involve advanced mathematics. Moreover (with one possible exception) I exclude also any mention of the numerous geometrical paradoxes which depend merely on the inability of the eye to compare correctly the dimensions of figures when their relative position is changed. This apparent deception does not involve the conscious reasoning powers, but rests on the inaccurate interpretation by the mind of the sensations derived through the eyes, and I do not consider such paradoxes as coming within the domain of mathematics. Geometrical Fallacies. Most educated Englishmen are acquainted with the series of logical propositions in geometry associated 35 36 SOME GEOMETRICAL QUESTIONS. [CH. II with the name of Euclid, but it is not known so generally that these propositions were supplemented originally by certain exercises. Of such exercises Euclid issued three series: two containing easy theorems or problems, and the third consisting of geometrical fallacies, the errors in which the student was required to find. The collection of fallacies prepared by Euclid is lost, and tradition has not preserved any record as to the nature of the erroneous reasoning or conclusions; but, as an illustration of such questions, I append two or three demonstrations, leading to obviously impossible results, which perhaps may amuse any one to whom they are new. I leave the discovery of the errors to the ingenuity

of my readers. First Fallacy. To prove that a right angle is equal to an angle which is greater than a right angle. Let ABCD be a rectangle. From A draw a line AE outside the rectangle, equal to AB or DC and making an acute angle with AB, as indicated in the diagram. Bisect CB in A C B D E O H K H, and through H draw HO at right angles to CB. Bisect CE in K, and through K draw KO at right angles to CE. Since CB and CE are not parallel the lines HO and KO will meet (say) at O. Join OA, OE, OC, and OD. The triangles ODC and OAE are equal in all respects. For, since KO bisects CE and is perpendicular to it, we have OC = OE. Similarly, since HO bisects CB and DA and is perpendicular to them, we have OD = OA. Also, by construction, DC = AE. Therefore the three sides of the triangle ODC are equal respectively to the three sides of CH. II] GEOMETRICAL FALLACIES. 37 the triangle OAE. Hence, by Euc. i. 8, the triangles are equal; and therefore the angle ODC is equal to the angle OAE. Again, since HO bisects DA and is perpendicular to it, we have the angle ODA equal to the angle OAD. Hence the angle ADC (which is the difference of ODC and ODA) is equal to the angle DAE (which is the difference of OAE and OAD). But ADC is a right angle, and DAE is necessarily greater than a right angle. Thus the result is impossible. Second Fallacy* . To prove that a part of a line is equal to the whole line. Let ABC be a triangle; and, to fix our ideas, let us suppose that the triangle is scalene, that the angle B is acute, and that the B C A D E angle A is greater than the angle C. From A draw AD making the angle BAD equal to the angle C, and cutting BC in D. From A draw AE perpendicular to BC. The triangles ABC, ABD are equiangular; hence, by Euc. vi. 19, △ABC : △ABD = AC2 : AD2 . Also the triangles ABC, ABD are of equal altitude: hence, by Euc. vi. 1, △ABC : △ABD = BC : BD , ∴ AC2 : AD2 = BC : BD . ∴ AC2 BC = AD2 BD . * See a note by M. Coccoz in L'Illustration, Paris, Jan. 12, 1895. 38 SOME GEOMETRICAL QUESTIONS. [CH. II Hence, by Euc. ii. 13, AB2 + BC2 − 2BC · BE BC = AB2 + BD2 − 2BD · BE BD . ∴ AB2 BC + BC − 2BE = AB2 BD + BD − 2BE . ∴ AB2 BC − BD = AB2 BD − BC . ∴ AB2 − BC · BD BC = AB2 − BC · BD BD . ∴ BC = BD , a result which is impossible. Third Fallacy. To prove that every triangle is isosceles. Let ABC be any triangle. Bisect BC in D, and through D draw DO perpendicular to BC. Bisect the angle BAC by AO. First. If DO and AO do not meet, then they are parallel. Therefore AO is at right angles to BC. Therefore AB = AC. Second. If DO and AO meet, let them meet in O. Draw OE perpendicular to AC. Draw OF perpendicular to AB. Join OB, OC. A B D C O E F Let us begin by taking the case where O is inside the triangle, in which case E falls on AC and F on1 AB. The triangles AOF and AOE are equal, since the side AO is common, angle OAF = angle OAE, and angle OF A = angle OEA. Hence AF = AE. Also, the triangles BOF and COE are equal. For since OD bisects BC at right angles, we have OB = OC; also, since the triangles AOF and AOE are equal, we have OF = OE; lastly, the angles at F and E are right angles. Therefore, by Euc. i. 47 and i. 8, the triangles BOF and COE are equal. Hence F B = EC. Therefore AF + F B = AE + EC, that is, AB = AC. The same demonstration will cover the case where DO

and AO meet at D, as also the case where they meet outside BC but so near it that E and F fall on AC and AB and not on AC and AB produced. 1. corrected BC to AB CH. II] GEOMETRICAL FALLACIES. 39 Next take the case where DO and AO meet outside the triangle, and E and F fall on AC and AB produced. Draw OE perpendicular to AC produced. Draw OF perpendicular to AB produced. Join OB, OC. A B D C O E F Following the same argument as before, from the equality of the triangles AOF and AOE, we obtain AF = AE; and, from the equality of the triangles BOF and COE, we obtain F B = EC. Therefore AF − F B = AE − EC, that is, AB = AC. Thus in all cases, whether or not DO and AO meet, and whether they meet inside or outside the triangle, we have AB = AC: and therefore every triangle is isosceles, a result which is impossible. Fourth Fallacy. I am indebted to Captain Turton for the following ingenious fallacy; it appeared for the first time in the third edition of this work. On the hypothenuse, BC, of an isosceles right-angled triangle, DBC, describe an equilateral triangle ABC, the vertex A being on the same side of the base as D is. On CA take a point H so that CH = CD. Bisect BD in K. Join HK and let it cut CB (produced) in L. Join DL. Bisect DL at M, and through M draw MO perpendicular to DL. Bisect HL at N, and through N draw NO perpendicular to HL. Since DL and HL intersect, therefore MO and NO will also intersect; moreover, since BDC is a right angle, MO and NO both slope away from DC and therefore they will meet on the side of DL remote from A. Join OC, OD, OH, OL. 40 SOME GEOMETRICAL QUESTIONS. [CH. II The triangles OMD and OML are equal, hence OD = OL. Similarly the triangles ONL and ONH are equal, hence OL = OH. Therefore OD = OH. Now in the triangles OCD and OCH, we have OD = OH, CD = CH (by construction), and OC common, hence (by Euc. i. 8) the angle OCD is equal to the angle OCH, which is absurd. Fifth Fallacy* . To prove that, if two opposite sides of a quadrilateral are equal, the other two sides must be parallel. Let ABCD be a quadrilateral such that AB is equal to DC. Bisect AD in M, and through M draw MO at right angles to AD. Bisect BC in N, and draw NO at right angles to BC. If MO and NO are parallel, then AD and BC (which are at right angles to them) are also parallel. If MO and NO are not parallel, let them meet in O; then O must be either inside the quadrilateral as in the left-hand diagram or outside A B C D N M O A B C D N M O the quadrilateral as in the right-hand diagram. Join OA, OB, OC, OD. Since OM bisects AD and is perpendicular to it, we have OA = OD, and the angle OAM equal to the angle ODM. Similarly OB = OC, and the angle OBN equal to the angle OCN. Also by hypothesis AB = DC, hence, by Euc. i. 8, the triangles OAB and ODC are equal in all respects, and therefore the angle AOB is equal to the angle DOC. Hence in the left-hand diagram the sum of the angles AOM, AOB is equal to the sum of the angles DOM, DOC; and in the right-hand * Mathesis, October, 1893, series 2, vol. iii, p. 224. CH. II] GEOMETRICAL FALLACIES. 41 diagram the difference of the angles AOM, AOB is equal to the difference of the angles DOM, DOC; and therefore in both cases the angle MOB is equal to the angle

MOC, i.e. OM (or OM produced) bisects the angle BOC. But the angle NOB is equal to the angle NOC, i.e. ON bisects the angle BOC; hence OM and ON coincide in direction. Therefore AD and BC, which are perpendicular to this direction, must be parallel. This result is not universally true, and the above demonstration contains a flaw. Sixth Fallacy. The following argument is taken from a text-book on electricity, published in 1889 by two distinguished mathematicians, in which it was presented as valid. A given vector OP of length l can be resolved in an infinite number of ways into two vectors OM, MP, of lengths l ′ , l ″, and we can make l ′/l″ have any value we please from nothing to infinity. Suppose that the system is referred to rectangular axes Ox, Oy; and that OP, OM, MP make respectively angles θ, θ ′ , θ ″ with Ox. Hence, by projection on Oy and on Ox, we have lsin θ = l ′ sin θ ′ + l ″ sin θ ″ , l cos θ = l ′ cos θ ′ + l ″ cos θ ″ . Therefore tan θ = n sin θ ′ + sin θ ″ n cos θ ′ + cos θ ″ , where n = l ′/l″. This result is true whatever be the value of n. But n may have any value (ex. gr. n = ∞, or n = 0), hence tan θ = tan θ ′ = tan θ ″, which obviously is impossible. Seventh Fallacy. Here is a fallacious investigation, to which Mr Chartres first called my attention, of the value of π: it is founded on well-known quadratures. The area of the semi-ellipse bounded by the minor axis is (in the usual notation) equal to 1 2 πab. If the centre is moved off to an indefinitely great distance along the major axis, the ellipse degenerates into a parabola, and therefore in this particular limiting position the area is equal to two-thirds of the circumscribing rectangle. But the first result is true whatever be the dimensions of the curve. ∴ 1 2 πab = 2 3 a × 2b, ∴ π = 8/3, a result which is obviously untrue. 42 SOME GEOMETRICAL QUESTIONS. [CH. II Geometrical Paradoxes. To the above examples I may add the following questions, which, though not exactly fallacious, lead to results which at a hasty glance appear impossible. First Paradox. The first is a problem, sent to me by Mr Renton, to rotate a plane lamina (say, for instance, a sheet of paper) through four right angles so that the effect is equivalent to turning it through only one right angle. If it is desired that the effect shall be equivalent to turning it through a right angle about a point O, the solution is as follows. Describe on the lamina a square OABC. Rotate the lamina successively through two right angles about the diagonal OB as axis and through two right angles about the side OA as axis, and the required result will be attained. Second Paradox. As in arithmetic, so in geometry, the theory of probability lends itself to numerous paradoxes. Here is a very simple illustration. A stick is broken at random into three pieces. It is possible to put them together into the shape of a triangle provided the length of the longest piece is less than the sum of the other two pieces (cf. Euc. i. 20), that is, provided the length of the longest piece is less than half the length of the stick. But the probability that a fragment of a stick shall be half the original length of the stick is 1 2 . Hence the probability that a triangle can be constructed out of the three pieces into which the stick is broken would appear to be 1 2 . This is not true, for actually the

probability is 1 4 . Third Paradox. The following example illustrates how easily the eye may be deceived in demonstrations obtained by actually dissecting the figures and re-arranging the parts. In fact proofs by superposition should be regarded with considerable distrust unless they are supplemented by mathematical reasoning. The well-known proofs of the propositions Euclid i. 32 and Euclid i. 47 can be so supplemented and are valid. On the other hand, as an illustration of how deceptive a nonmathematical proof may be, I here mention the familiar paradox that a square of paper, subdivided like a chessboard into 64 small squares, can be cut into four pieces which being put together form a figure containing 65 such small squares* . This is effected by cutting the original * I do not know who discovered this paradox. It is given in various modern books, but I cannot find an earlier reference to it than one by Prof. G.H. Darwin, Messenger of Mathematics, 1877, vol. vi, p. 87. CH. II] GEOMETRICAL PARADOXES. 43 A B square into four pieces in the manner indicated by the thick lines in the first figure. If these four pieces are put together in the shape of a rectangle in the way shown in the second figure it will appear as if this rectangle contains 65 of the small squares. This phenomenon, which in my experience non-mathematicians find perplexing, is due to the fact that the edges of the four pieces of paper, which in the second figure lie along the diagonal AB, do not coincide exactly in direction. In reality they include a small lozenge or diamond-shaped figure, whose area is equal to that of one of the 64 small squares in the original square, but whose length AB is much greater than its breadth. The diagrams show that the angle between the two sides of this lozenge which meet at A is tan−1 2 5 − tan−1 3 8 , that is, is tan−1 1 46 , which is less than 1 1 4 ◦ . To enable the eye to distinguish so small an angle as this the dividing lines in the first figure would have to be cut with extreme accuracy and the pieces placed together with great care. The paradox depends upon the relation 5 × 13 − 8 2 = 1. Similar results can be obtained from the formulae 13 × 34 − 212 = 1, 34×89−552 = 1,. . . ; or from the formulae 5 2−3×8 = 1, 132−8×21 = 1, 342 − 21 × 55 = 1,. . . . These numbers are obtained by finding convergents to the continued fraction 1 + 1 1 + 1 1 + 1 1 + · · · . A similar paradox for a square of 17 cells, by which it was shown that 289 was equal to 288, was alluded to by Ozanam* who gave also the diagram for dividing a rectangle of 11 by 3 into two rectangles whose dimensions appear to be 5 by 4 and 7 by 2. * Ozanam, 1803 edition, vol. i, p. 299. 44 SOME GEOMETRICAL QUESTIONS. [CH. II Turton's Seventy-Seven Puzzle. A far better dissection puzzle was invented by Captain Turton. In this a piece of cardboard, 11 inches by 7 inches, subdivided into 77 small equal squares, each 1 inch by 1 inch, can be cut up and re-arranged so as to give 78 such equal squares, each 1 inch by 1 inch, of which 77 are arranged in a rectangle of the same dimensions as the original rectangle from one side of which projects a small additional square. The construction is ingenious, but cannot be described without the use of a model. The trick consists in

utilizing the fact that cardboard has a sensible thickness. Hence the edges of the cuts can be bevelled, but in the model the bevelling is so slight as to be imperceptible save on a very close scrutiny. The play thus given in fitting the pieces together permits the apparent production of an additional square. Colouring Maps. I proceed next to mention the geometrical proposition that not more than four colours are necessary in order to colour a map of a country (divided into districts) in such a way that no two contiguous districts shall be of the same colour. By contiguous districts are meant districts having a common line as part of their boundaries: districts which touch only at points are not contiguous in this sense. The problem was mentioned by A.F. Möbius* in his Lectures in 1840, but it was not until Francis Guthrie† communicated it to De Morgan about 1850 that attention was generally called to it: it is said that the fact had been familiar to practical map-makers for a long time previously. Through De Morgan the proposition became generally known; and in 1878 Cayley‡ recalled attention to it by stating that he did not know of any rigorous proof of it. Probably the following argument, though not a formal demonstration, will satisfy the reader that the result is true. Let A, B, C be three contiguous districts, and let X be any other district contiguous with all of them. Then X must lie either wholly outside the external boundary of the area ABC or wholly inside the internal boundary, that is, it must occupy a position either like X or * Leipzig Transactions (Math.-phys. Classe), 1885, vol. xxxvii, pp. 1–6. † Proceedings of the Royal Society of Edinburgh, July 19, 1880, vol. x, p. 728. ‡ Proceedings of the London Mathematical Society, 1878, vol. ix, p. 148, and Proceedings of the Royal Geographical Society, 1879, N.S., vol. i, p. 259. CH. II] THE FOUR-COLOUR THEOREM.. 45 like X’ . In either case every remaining occupied area in the figure is enclosed by the boundaries of not more than three districts: hence there is no possible way of drawing another area Y which shall be contiguous with A, B, C, and X. In other words, it is possible to draw on a plane four areas which are contiguous, but it is not possible to draw five such areas. If A, B, C are not contiguous, each with the other, or if X is not contiguous with A, B, and C, it is not necessary to colour them all differently, and thus the most unfavourable case is that already treated. Moreover any of the above areas may diminish to a point and finally disappear without affecting the argument. That we may require at least four colours is obvious from the diagram on this page, since in that case the areas A, B, C, and X would have to be coloured differently. A proof of the proposition involves difficulties of a high order, which as yet have baffled all attempts to surmount them. The argument by which the truth of the proposition was formerly supposed to be demonstrated was given by A.B. Kempe* in 1879, but * He sent his first demonstration across the Atlantic to the American Journal of Mathematics, 1879, vol. ii, pp. 193–200; but subsequently he communicated it 46 SOME GEOMETRICAL QUESTIONS. [CH. II there is a flaw* in it. In 1880, Tait published a solution† depending on the theorem that if a closed network of

lines joining an even number of points is such that three and only three lines meet at each point then three colours are sufficient to colour the lines in such a way that no two lines meeting at a point are of the same colour; a closed network being supposed to exclude the case where the lines can be divided into two groups between which there is but one connecting line. His deduction therefrom that four colours will suffice for a map was given in the last edition of this work. The demonstration appeared so straightforward that at first it was generally accepted, but it would seem that it too involves a fallacy‡ . The proof however leads to the interesting corollary that four colours may not suffice for a map drawn on a multiply-connected surface such as an anchor ring. Although a proof of the theorem is still wanting, no one has succeeded in constructing a plane map which requires more than four tints to colour it, and there is no reason to doubt the correctness of the statement that it is not necessary to have more than four colours for any plane map. The number of ways which such a map can be coloured with four tints has been also considered§ , but the results are not sufficiently interesting to require mention here. Physical Configuration of a Country. As I have been alluding to maps, I may here mention that the theory of the representation of the physical configuration of a country by means of lines drawn on a map was discussed, by Cayley and Clerk Maxwell‖ . They in simplified forms to the London Mathematical Society, Transactions, 1879, vol. x, pp. 229–231, and to Nature, Feb. 26, 1880, vol. xxi, pp. 399–400. * See articles by P.J. Heawood in the Quarterly Journal of Mathematics, London, 1890, vol. xxiv, pp. 332–338; and 1897, vol. xxxi, pp. 270–285. † Proceedings of the Royal Society of Edinburgh, July 19, 1880, vol. x, p. 729; and Philosophical Magazine, January, 1884, series 5, vol. xvii, p. 41. ‡ See J. Peterson of Copenhagen, L'Intermédiaire des mathématiciens, vol. v, 1898, pp. 225–227; and vol. vi, 1899, pp. 36–38. § See A.C. Dixon, Messenger of Mathematics, Cambridge, 1902–3, vol. xxxii, pp. 81–83. ‖ Cayley on 'Contour and Slope Lines,' Philosophical Magazine, London, October, 1859, series 4, vol. xviii, pp. 264–268; Collected Works, vol. iv, pp. 108–111. J. Clerk Maxwell on 'Hills and Dales,' Philosophical Magazine, December, 1870, series 4, vol. xl, pp. 421–427; Collected Works, vol. ii, pp. 233–240. CH. II] HILLS AND DALES.. 47 showed that a certain relation exists between the number of hills, dales, passes, &c. which can co-exist on the earth or on an island. I proceed to give a summary of their nomenclature and conclusions. All places whose heights above the mean sea level are equal are on the same level. The locus of such points on a map is indicated by a contour-line. Roughly speaking, an island is bounded by a contour-line. It is usual to draw the successive contour-lines on a map so that the difference between the heights of any two successive lines is the same, and thus the closer the contour-lines the steeper is the slope, but the heights are measured dynamically by the amount of work to be done to go from one level to the other and not by linear distances. A contour-line in general will be a closed curve. This curve

may enclose a region of elevation: if two such regions meet at a point, that point will be a crunode (i.e. a real double point) on the contour-line through it, and such a point is called a pass. The contour-line may enclose a region of depression: if two such regions meet at a point, that point will be a crunode on the contour-line through it, and such a point is called a fork or bar. As the heights of the corresponding level surfaces become greater, the areas of the regions of elevation become smaller, and at last become reduced to points: these points are the summits of the corresponding mountains. Similarly as the level surface sinks the regions of depression contract, and at last are reduced to points: these points are the bottoms (or immits) of the corresponding valleys. Lines drawn so as to be everywhere at right angles to the contourlines are called lines of slope. If we go up a line of slope generally we shall reach a summit, and if we go down such a line generally we shall reach a bottom: we may come however in particular cases either to a pass or to a fork. Districts whose lines of slope run to the same summit are hills. Those whose lines of slope run to the same bottom are dales. A watershed is the line of slope from a summit to a pass or a fork, and it separates two dales. A watercourse is the line of slope from a pass or a fork to a bottom, and it separates two hills. If n + 1 regions of elevation or of depression meet at a point, the point is a multiple point on the contour-line drawn through it; such a point is called a pass or a fork of the nth order, and must be counted as n separate passes (or forks). If one region of depression meets another in several places at once, one of these must be taken as a fork and the rest as passes. 48 SOME GEOMETRICAL QUESTIONS. [CH. II Having now a definite geographical terminology we can apply geometrical propositions to the subject. Let h be the number of hills on the earth (or an island), then there will be also h summits; let d be the number of dales, then there will be also d bottoms; let p be the whole number of passes, p1 that of single passes, p2 of double passes, and so on; let f be the whole number of forks, f1 that of single forks, f2 of double forks, and so on; let w be the number of watercourses, then there will be also w watersheds. Hence, by the theorems of Cauchy and Euler, h = 1 + p1 + 2p2 + · · · , d = 1 + f1 + 2f2 + · · · , and w = 2(p1 + f1) + 3(p2 + f2)) + · · · . The above results can be extended to the case of a multiplyconnected closed surface. Games. Leaving now the question of formal geometrical propositions, I proceed to enumerate a few games or puzzles which depend mainly on the relative position of things, but I postpone to chapter iv the discussion of such amusements of this kind as necessitate any considerable use of arithmetic or algebra. Some writers regard draughts, solitaire, chess and such like games as subjects for geometrical treatment in the same way as they treat dominoes, backgammon, and games with dice in connection with arithmetic: but these discussions require too many artificial assumptions to correspond with the games as actually played or to be interesting. The amusements to which I refer are of a more trivial description, and it is possible that a mathematician

may like to omit the remainder of the chapter. In some cases it is difficult to say whether they should be classified as mainly arithmetical or geometrical, but the point is of no importance. Statical Games of Position. Of the innumerable statical games involving geometry of position I shall mention only three or four. Three-in-a-row. First, I may mention the game of three-in-a-row, of which noughts and crosses, one form of merrilees, and go-bang are well-known examples. These games are played on a board—generally in the form of a square containing n 2 small squares or cells. The common practice is for one player to place a white counter or piece or to make CH. II] THREE-IN-A-ROW.. 49 a cross on each small square or cell which he occupies: his opponent similarly uses black counters or pieces or makes a nought on each square which he occupies. Whoever first gets three (or any other assigned number) of his pieces in three adjacent cells and in a straight line wins. The mathematical theory for a board of 9 cells has been worked out completely, and there is no difficulty in extending it to one of 16 cells: but the analysis is lengthy and not particularly interesting. Most of these games were known to the ancients* , and it is for that reason I mention them here. Three-in-a-row. Extension. I may, however, add an elegant but difficult extension which has not previously found its way, so far as I am aware, into any book of mathematical recreations. The problem is to place n counters on a plane so as to form as many rows as possible, each of which shall contain three and only three counters† . It is easy to arrange the counters in a number of rows equal to the integral part of 1 8 (n − 1)2 . This can be effected by the following construction. Let P be any point on a cubic. Let the tangent at P cut the curve again in Q. Let the tangent at Q cut the curve in A. Let P A cut the curve in B, QB cut it in C, P C cut it in D, QD cut it in E, and so on. Then the counters must be placed at the points P, Q, A, B, ... Thus 9 counters can be placed in 8 such rows; 10 counters in 10 rows; 15 counters in 24 rows; 81 counters in 800 rows; and so on. If however the point P is a pluperfect point of the nth order on the cubic, then Sylvester proved that the above construction gives a number of rows equal to the integral part of 1 6 (n − 1)(n − 2). Thus 9 counters can be arranged in 9 rows, which is a well-known and easy puzzle; 10 counters in 12 rows; 15 counters in 30 rows; and so on. Even this however is an inferior limit and may be exceeded—for instance, Sylvester stated that 9 counters can be placed in 10 rows, each containing three counters; I do not know how he placed them, but one way of so arranging them is by putting them at points whose coordinates are (2, 0), (2, 2), (2, 4), (4, 0), (4, 2), (4, 4), (0, 0), (3, 2), (6, 4); another way is by putting them at the points (0, 0), (0, 2), (0, 4), (2, 1), (2, 2), (2, 3), (4, 0), (4, 2), (4, 4); more generally, the angular points of * Becq de Fouquières, Les jeux des anciens, second edition, Paris, 1873, chap. xviii. † Educational Times Reprints, 1868, vol. viii, p. 106; Ibid. 1886, vol. xlv, pp. 127– 128. 50 SOME GEOMETRICAL QUESTIONS. [CH. II a regular hexagon and the three points of intersection of opposite sides form such a group, and therefore

any projection of that figure will give a solution. Thus at present it is not possible to say what is the maximum number of rows of three which can be formed from n counters placed on a plane. Extension to p-in-a-row. The problem mentioned above at once suggests the extension of placing n counters so as to form as many rows as possible, each of which shall contain p and only p counters. Such problems can be often solved immediately by placing at infinity the points of intersection of some of the lines, and (if it is so desired) subsequently projecting the diagram thus formed so as to bring these points to a finite distance. One instance of such a solution is given above. As easy examples I may give the arrangement of 16 counters in 15 rows1 , each containing 4 counters; and the arrangement of 19 counters in 10 rows, each containing 5 counters. A solution of the second of these problems can be obtained by placing counters at the 19 points of intersection of the 10 lines $x = \pm a$, $x = \pm b$, $y = \pm a$, $y = \pm b$, $y = \pm x$: of these points two are at infinity. The first problem I leave to the ingenuity of my readers. Tesselation. Another of these statical recreations is known as tesselation and consists in the formation of geometrical designs or mosaics by means of tesselated tiles. To those who have never looked into the matter it may be surprising that patterns formed by the use of square tiles (of which one-half bounded by a diagonal is white and the other half black) should be subject to mathematical analysis. In view of the discussion of this subject by Montucla* , Lucas† , and other writers it would be hard to refuse to call the formation of such patterns a mathematical amusement, but the treatment is (perhaps necessarily) somewhat empirical, and though there are some interesting puzzles of this kind, I do not propose to describe them here. * See Ozanam, 1803 edition, vol. i, p. 100; 1840 edition, p. 46. † Lucas, Récréations Mathématiques, Paris, 1882–3, vol. ii, part 4: hereafter I shall refer to this work by the name of the author. 1. ‘13’ corrected to ’15’ as per errata sheet CH. II] COLOUR-CUBE PROBLEM. 51 Sylvester* proposed a modified tesselation problem which consists in forming anallagmatic squares, that is, squares such that in every row and every column the number of changes of colour or the number of permanences is constant, the tiles used being square white tiles and square black tiles. If more than two colours are used, the problems become increasingly difficult. As a simple instance of this class of problems I may mention one, sent to me by a correspondent who termed it Cross-Fours, wherein sixteen square counters are used, the upper half of each being yellow, red, pink, or blue, and the lower half being gold, green, black, or white, no two counters being coloured alike. Such counters can be arranged in the form of a square so that in each vertical, horizontal, and diagonal line there shall be 8 colours and no more: they can be also arranged so that in each of these ten lines there shall be 6 colours and no more, or 5 colours and no more, or 4 colours and no more. Puzzles of this kind are but little known; they are however not uninstructive. Colour-Cube Problem. As an example of a recreation

analogous to tesselation I will mention the colour-cube problem; I select this partly because it is one of the most difficult of such puzzles, but chiefly because it has been subjected† to mathematical analysis. Stripped of mathematical technicalities the problem may be enunciated as follows. A cube has six faces, and if six colours are chosen we can paint each face with a different colour. By permuting the order of the colours we can obtain thirty such cubes, no two of which are coloured alike. Take any one of these cubes, K, then it is desired to select eight out of the remaining twenty-nine cubes, such that they can be arranged in the form of a cube (whose linear dimensions are double those of any of the separate cubes) coloured like the cube K, and placed so that where any two cubes touch each other the faces in contact are coloured alike. Only one collection of eight cubes can be found to satisfy these conditions. To pick out these eight cubes empirically would be out of the question, but the mathematical analysis enables us to select them by the following rule. Take any face of the cube K: it has four * Ex. gr. see the Educational Times Reprints, London, 1868, vol. x, pp. 74–76, 112: see also vol. xlv, p. 127; vol. lvi, pp. 97–99. † By Major MacMahon; an abstract of his paper, read before the London Mathematical Society on Feb. 9, 1893, was given in Nature, Feb. 23, 1893, vol. xlvii, p. 406. 52 SOME GEOMETRICAL QUESTIONS. [CH. II angles, and at each angle three colours meet. By permuting the colours cyclically we can obtain from each angle two other cubes, and the eight cubes so obtained are those required. For instance suppose that the six colours are indicated by the letters a, b, c, d, e, f. Let the cube K be put on a table, and to fix our ideas suppose that the face coloured f is at the bottom, the face coloured a is at the top, and the faces coloured b, c, d, and e front respectively the east, north, west, and south points of the compass. I may denote such an arrangement by (f; a; b, c, d, e). One cyclical permutation of the colours which meet at the north-east corner of the top face gives the cube (f; c; a, b, d, e), and a second cyclical permutation gives the cube (f; b; c, a, d, e). Similarly cyclical permutations of the colours which meet at the north-west corner of the top face of K give the cubes (f; d; b, a, c, e) and (f; c; b, d, a, e). Similarly from the top south-west corner of K we get the cubes (f; e; b, c, a, d) and (f; d; b, c, e, a): and from the top south-east corner we get the cubes (f; e; a, c, d, b) and (f; b; e, c, d, a). The eight cubes being thus determined it is not difficult to arrange them in the form of a cube coloured similarly to K, and subject to the condition that faces in contact are coloured alike; in fact they can be arranged in two ways to satisfy these conditions. One such way, taking the cubes in the numerical order given above, is to put the cubes 3, 6, 8, and 2 at the SE, NE, NW, and SW corners of the bottom face; of course each placed with the colour f at the bottom, while 3 and 6 have the colour b to the east, and 2 and 8 have the colour d to the west: the cubes 7, 1, 4, and 5 will then form the SE, NE, NW, and SW corners of the top face; of course each placed with the colour a at the top, while 7 and 1 have the colour b to the east, and 5 and 4 have

the colour d to the west. If however K is not given, then, without the aid of mathematical analysis, it is a difficult puzzle to arrange the eight cubes in the form of a cube coloured similarly to one of the other twenty-two cubes and subject to the condition that faces in contact are coloured alike. It is easy to make similar puzzles in two dimensions which are fairly difficult; it is somewhat surprising that none are to be bought, but I have never seen any except those that I have made myself. Dynamical Games of Position. Games which are played by moving pieces on boards of various shapes—such as merrilees, fox and geese, solitaire, backgammon, draughts, and chess—present more CH. II] SHUNTING PROBLEMS. 53 interest. In general, however, they permit of so many movements of the pieces that any mathematical analysis of them becomes too intricate to follow out completely. Probably this is obvious, but it may emphasize the impossibility of discussing such games effectively if I add that it has been shown that in a game of chess there may be as many as 197299 ways of playing the first four moves, and nearly 72000 different positions at the end of the first four moves (two on each side), of which 16556 arise when the players move pawns only* . Games in which the possible movements are very limited may be susceptible of mathematical treatment. One or two of these are given in the next chapter: here I shall confine myself mainly to puzzles and simple amusements. Shunting Problems. The first I will mention is a little puzzle which I bought some years ago and which was described as the “Great Northern puzzle.” It is typical of a good many problems connected with the shunting of trains, and though it rests on a most improbable hypothesis, I give it as a specimen of its kind. A BC DE F P Q R The puzzle shows a railway, DEF, with two sidings, DBA and F CA, connected at A. The portion of the rails at A which is common to the two sidings is long enough to permit of a single wagon, like P or Q, running in or out of it; but is too short to contain the whole of an engine, like R. Hence, if an engine runs up one siding, such as DBA, it must come back the same way. * L’Intermédiaire des mathématiciens, Paris, December, 1903, vol. x, pp. 305– 308: also Royal Engineers Journal, London, August–November, 1889; or British Association Transactions, 1890, p. 745. 54 SOME GEOMETRICAL QUESTIONS. [CH. II Initially a small block of wood, P, coloured to represent a wagon, is placed at B; a similar block, Q, is placed at C; and a longer block of wood, R, representing an engine, is placed at E. The problem is to use the engine R to interchange the wagons P and Q, without allowing any flying shunts. This is effected thus. (i) R pushes P into A. (ii) R returns, pushes Q up to P in A, couples Q to P, draws them both out to F, and then pushes them to E. (iii) P is now uncoupled, R takes Q back to A, and leaves it there. (iv) R returns to P, pulls P back to C, and leaves it there. (v) R running successively through F, D, B comes to A, draws Q out, and leaves it at B. A somewhat similar puzzle, on sale in the streets in 1905, is made as follows. A loop-line BGE connects two points B and E on a railway track AF, which is supposed blocked at both ends, as shown in the diagram.

In the model, the track AF is 9 inches long, AB = EF = 1 5 6 inches, and AH = FK = BC = DE = 1 4 inch. On the track and loop are eight wagons, numbered successively 1 to 8, each one inch long and AB CD EF G HK one-quarter of an inch broad, and an engine of the same dimensions. Originally the wagons are on the track from A to F and in the order 1, 2, 3, 4, 5, 6, 7, 8, and the engine is on the loop. The construction and the initial arrangement ensure that at any one time there cannot be more than eight vehicles on the track. Also if eight vehicles are on it only the penultimate vehicle at either end can be moved on to the loop, but if less than eight are on the track then the last two vehicles at either end can be moved on to the loop. If the points at each end of the loop-line are clear, it will hold four, but not more than four, vehicles. The object is to reverse the order of the wagons on the track, so that from A to F they will be numbered successively 8 to 1; and to do this by means which will involve as few transferences of the engine or a wagon to or from the loop as is possible. Other shunting problems are not uncommon, but these two examples will suffice. CH. II] FERRY-BOAT PROBLEMS. 55 Ferry-Boat Problems. Everybody is familiar with the story of the showman who was travelling with a wolf, a goat, and a basket of cabbages; and for obvious reasons was unable to leave the wolf alone with the goat, or the goat alone with the cabbages. The only means of transporting them across a river was a boat so small that he could take in it only one of them at a time. The problem is to show how the passage could be effected* . A similar problem, given by Alcuin, Tartaglia, and others, is as follows† . Three beautiful ladies have for husbands three men, who are as jealous as they are young, handsome, and gallant. The party are travelling, and find on the bank of a river, over which they have to pass, a small boat which can hold no more than two persons. How can they pass, it being agreed that, in order to avoid scandal, no woman shall be left in the society of a man unless her husband is present? The method of transportation to be used in the above cases is obvious, and can be illustrated practically by using six court cards out of a pack. Another problem similar to the one last mentioned is the case of n married couples who have to cross a river by means of a boat which can be rowed by one person and will carry n − 1 people, but not more, with the condition that no woman is to be in the society of a man unless her husband is present. Alcuin’s problem is the case of n = 3. Let y denote the number of passages from one bank to the other which will be necessary. Then it has been shown that if n = 3, y = 11; if n = 4, y = 9; and if n > 4, y = 7; the demonstration presents no difficulty. The following analogous problem is due to the late Prof. Lucas‡ . To find the smallest number x of persons that a boat must be able to carry in order that n married couples may by its aid cross a river in such a manner that no woman shall remain in the company of any man unless her husband is present; it being assumed that the boat can be rowed by one person only. Also to find the least number of passages, say y, from one bank to the other which will be required. M.

Delannoy has shown that if n = 2, then x = 2, and y = 5. If n = 3, then x = 2, and y = 11. If n = 4, then x = 3, and y = 9. If n = 5, then x = 3, and y = 11. And finally if n > 5, then x = 4, and y = 2n − 1. M. De Fonteney has remarked that, if there was an island in the * Ozanam, 1803 edition, vol. i, p. 171; 1840 edition, p. 77. † Bachet, Appendix, problem iv, p. 212. ‡ Lucas, vol. i, pp. 15–18, 237–238. 56 SOME GEOMETRICAL QUESTIONS. [CH. II middle of the river, the passage might be always effected by the aid of a boat which could carry only two persons. If there are only two or only three couples the island is unnecessary, and the case is covered by the preceding method. If n > 3 then the least number of passages from land to land which will be required is 8(n − 1). His solution is as follows. The first nine passages will be the same, no matter how many couples there may be: the result is to transfer one couple to the island and one couple to the second bank. The result of the next eight passages is to transfer one couple from the first bank to the second bank: this series of eight operations must be repeated as often as necessary until there is left only one couple on the first bank, only one couple on the island, and all the rest on the second bank. The result of the last seven passages is to transfer all the couples to the second bank. The solution for the case when there are four couples may be represented as follows. Let A and a, B and b, C and c, D and d, be the four couples. The letters in the successive lines indicate the positions of the men and their respective wives after different passages of the boat. Tarry has suggested an extension of the problem, which still further complicates its solution. He supposes that each husband travels with a harem of m wives or concubines; moreover, as Mohammedan women are brought up in seclusion, it is reasonable to suppose that they would be unable to row a boat by themselves without the aid of a man. But perhaps the difficulties attendant on the travels of one wife may be deemed sufficient for Christians, and I content myself with merely mentioning the increased anxieties experienced by Mohammedans in similar circumstances. Geodesics. Geometrical problems

Zaid n. adwan

connected with finding the shortest routes from one point to another on a curved surface are often difficult, but geodesics on a flat surface or flat surfaces are in general readily determinable. I append an instance* , but I should have hesitated to do so had not experience shown that some readers do not readily see the solution. It is as follows: A room is 30 feet long, 12 feet wide, and 12 feet high. On the middle line of one of the smaller side walls and one foot from the ceiling is a wasp. On the middle line of the opposite wall and 11 feet from the ceiling is a fly. The wasp catches the fly by crawling all the way to it: the fly, paralysed by fear, remaining still. The problem is to find the shortest route that the wasp can follow. To obtain a solution we observe that we can cut a sheet of paper so that, when folded properly, it will make a model to scale of the room. This can be done in several ways. If, when the paper is again spread out flat, we can join the points representing the wasp and the fly by a straight line lying wholly on the paper we shall obtain a geodesic route between them. Thus the problem is reduced to finding the way of cutting out the paper which gives the shortest route of the kind. * I heard a similar question propounded at Cambridge in 1903, but the only place where I have seen it in print is the Daily Mail, London, February 1, 1905. 58 SOME GEOMETRICAL QUESTIONS. [CH. II A B C D W F Here is the diagram corresponding to a solution of the above question, where A represents the floor, B and D the longer side-walls, C the ceiling, and W and F the positions on the two smaller side-walls occupied initially by the wasp and fly. In the diagram the square of the distance between W and F is (32)2+(24)2 ; hence the distance is 40 feet. Problems with Counters placed in a row. Numerous dynamical problems and puzzles may be illustrated with a box of counters, especially if there are counters of two colours. Of course coins or pawns or cards will serve equally well. I proceed to enumerate a few of these played with counters placed in a row. First Problem with Counters. The following problem must be familiar to many of my readers. Ten counters (or coins) are placed in a row. Any counter may be moved over two of those adjacent to it on the counter next beyond them. It is required to move the counters according to the above rule so that they shall be arranged in five equidistant couples. If we denote the counters in their initial positions by the numbers 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, we proceed as follows. Put 7 on 10, then 5 on 2, then 3 on 8, then 1 on 4, and lastly 9 on 6. Thus they are arranged in pairs on the places originally occupied by the counters 2, 4, 6, 8, 10. Similarly by putting 4 on 1, then 6 on 9, then 8 on 3, then 10 on CH. II] PROBLEMS WITH COUNTERS.. 59 7, and lastly 2 on 5, they are arranged in pairs on the places originally occupied by the counters 1, 3, 5, 7, 9. If two superposed counters are reckoned as only one, solutions analogous to those given above will be obtained by putting 7 on 10, then 5 on 2, then 3 on 8, then 1 on 6, and lastly 9 on 4; or by putting 4 on 1, then 6 on 9, then 8 on 3, then 10 on 5, and lastly 2 on 7 * . There is a somewhat similar game played with eight counters, but in this case the four couples

finally formed are not equidistant. Here the transformation will be effected if we move 5 on 2, then 3 on 7, then 4 on 1, and lastly 6 on 8. This form of the game is applicable equally to (8 + 2n) counters, for if we move 4 on 1 we have left on one side of this couple a row of (8 + 2n − 2) counters. This again can be reduced to one of (8 + 2n − 4) counters, and in this way finally we have left 8 counters which can be moved in the way explained above. A more complete generalization would be the case of n counters, where each counter might be moved over the m counters adjacent to it on to the one beyond them. Second Problem with Counters. Another problem of a somewhat similar kind is due to Tait† . Place four florins (or white counters) and four halfpence (or black counters) alternately in a line in contact with one another. It is required in four moves, each of a pair of two contiguous pieces, without altering the relative position of the pair, to form a continuous line of four halfpence followed by four florins. His solution is as follows. Let a florin be denoted by a and a halfpenny by b, and let ×× denote two contiguous blank spaces. Then the successive positions of the pieces may be represented thus: Initially . . . . . × × a b a b a b a b . After the first move . . . . . b a a b a b a × × b . After the second move . . b a a b × × a a b b . After the third move . . . . b × × b a a a a b b . After the fourth move . . . b b b b a a a a × ×. The operation is conducted according to the following rule. Suppose the pieces to be arranged originally in circular order, with two contiguous blank spaces, then we always move to the blank space for * Note by J. Fitzpatrick to a French translation of the third edition of this work, Paris, 1898. † Philosophical Magazine, London, January, 1884, series 5, vol. xvii, p. 39. 60 SOME GEOMETRICAL QUESTIONS. [CH. II the time being that pair of coins which occupies the places next but one and next but two to the blank space on one assigned side of it. A similar problem with 2n counters—n of them being white and n black—will at once suggest itself, and, if n is greater than 4, it can be solved in n moves. I have however failed to find a simple rule which covers all cases alike, but solutions, due to M. Delannoy, have been given* for the four cases where n is of the form 4m, 4m + 2, 4m + 1, or 4m+3; in the first two cases the first 1 2 n moves are of pairs of dissimilar counters and the last 1 2 n moves are of pairs of similar counters; in the last two cases, the first move is similar to that given above, namely, of the penultimate and antepenultimate counters to the beginning of the row, the next 1 2 (n − 1) moves are of pairs of dissimilar counters, and the final 1 2 (n − 1) moves are of similar counters. The problem is also capable of solution if we substitute the restriction that at each move the pair of counters taken up must be moved to one of the two ends of the row instead of the condition that the final arrangement is to be continuous. Tait suggested a variation of the problem by making it a condition that the two coins to be moved shall also be made to interchange places; in this form it would seem that 5 moves are required; or, in the general case, n + 1 moves are required. Problems on a Chess-board with Counters or Pawns.

The following three problems require the use of a chess-board as well as of counters or pieces of two colours. It is more convenient to move a pawn than a counter, and if therefore I describe them as played with pawns it is only as a matter of convenience and not that they have any connection with chess. The first is characterized by the fact that in every position not more than two moves are possible; in the second and third problems not more than four moves are possible in any position. With these limitations, analysis is possible. I shall not discuss the similar problems in which more moves are possible. First Problem with Pawns† . On a row of seven squares on a chessboard 3 white pawns (or counters), denoted in the diagram by “a”s, are placed on the 3 squares at one end, and 3 black pawns (or counters), denoted by “b”s, are placed on the 3 squares at the other end—the middle square being left vacant. Each piece can move only in one * La Nature, June, 1887, p. 10. † Lucas, vol. ii, part 5, pp. 141-143. CH. II] PROBLEMS WITH COUNTERS OR PAWNS. 61 direction; the “a” pieces can move from left to right, and the “b” pieces from right to left. If the square next to a piece is unoccupied, it can a a a b b b move on to that; or if the square next to it is occupied by a piece of the opposite colour and the square beyond that is unoccupied, then it can, like a queen in draughts, leap over that piece on to the unoccupied square beyond it. The object is to get all the white pawns in the places occupied initially by the black pawns and vice versa. The solution requires 15 moves. It may be effected by moving first a white pawn, then successively two black pawns then three white pawns, then three black pawns, then three white pawns, then two black pawns, and then one white pawn. We can express this solution by saying that if we number the cells (a term used to describe each of the small squares on a chess-board) consecutively, then initially the vacant space occupies the cell 4 and in the successive moves it will occupy the cells 3, 5, 6, 4, 2, 1, 3, 5, 7, 6, 4, 2, 3, 5, 4. Of these moves, six are simple and nine are leaps. Similarly if we have n white pawns at one end of a row of 2n + 1 cells, and n black pawns at the other end, they can be interchanged in n(n+2) moves, by moving in succession 1 pawn, 2 pawns, 3 pawns, . . . , n − 1 pawns, n pawns, n pawns, n pawns, n − 1 pawns, . . . , 2 pawns, and 1 pawn—all the pawns in each group being of the same colour and different from that of the pawns in the group preceding it. Of these moves 2n are simple and n 2 are leaps. Second Problem with Pawns* . A similar game may be played on a rectangular or square board. The case of a square board containing 49 cells, or small squares, will illustrate this sufficiently: in this case the initial position is shown in the annexed diagram where the “a”s denote the pawns or pieces of one colour, and the “b”s those of the other colour. The “a” pieces can move horizontally from left to right or vertically down, and the “b” pieces can move horizontally from right to left or vertically up, according to the same rules as before. The solution reduces to the preceding case. The pieces in the middle column can be interchanged in 15 moves. In the course of these moves

every one of the seven cells in that column is at some time or * Lucas, vol. ii, part 5, p. 144. 62 SOME GEOMETRICAL QUESTIONS. [CH. II a a a a b b b a a a a b b b a a a a b b b a a a b b b a a a b b b a a a b b b a a a b b b b a a a b b b b other vacant, and whenever that is the case the pieces in the row containing the vacant cell can be interchanged. To interchange the pieces in each of the seven rows will require 15 moves. Hence to interchange all the pieces will require 15 + (7 × 15) moves, that is, 120 moves. If we place 2n(n + 1) white pawns and 2n(n + 1) black pawns in a similar way on a square board of (2n + 1)2 cells, we can transpose them in 2n(n + 1)(n + 2) moves: of these 4n(n + 1) are simple and 2n 2 (n + 1) are leaps. Third Problem with Pawns. The following analogous, though somewhat more complicated, game was I believe originally published in the first edition of this work: but I find that it has been since widely a b c d e f g h ∗ H G F E D C B A distributed in connexion with an advertisement and probably now is well-known. On a square board of 25 cells, place eight white pawns or counters on the cells denoted by small letters in the annexed diagram, and eight black pawns or counters on the cells denoted by capital letters: the cell marked with an asterisk (∗) being left blank. Each pawn can move according to the laws already explained—the white pawns being able to move only horizontally from left to right or vertically downwards, and the black pawns being able to move only horizontally from right to left or vertically upwards. The object is to get all the CH. II] PROBLEMS WITH CHESS-PIECES 63 white pawns in the places initially occupied by the black pawns and vice versa. No moves outside the dark line are permitted. Since there is only one cell on the board which is unoccupied, and since no diagonal moves and no backward moves are permitted, it follows that at each move not more than two pieces of either colour are capable of moving. There are however a very large number of solutions. The following empirical solution in forty-eight moves is one way of effecting the transfer—the letters indicating the cells from which the pieces are successively moved: h H ∗ f F E H G ∗ c b h g d f F C ∗ h H B A C ∗ c a b h H ∗ c f F D G H B C ∗ g h e f F ∗ h H ∗ . It will be noticed that the first twenty-four moves lead to a symmetrical position, and that the next twenty-three moves can be at once obtained by writing the first twenty-three moves in reverse order and interchanging small and capital letters. Probably, were it worth the trouble, the mathematical theory of games such as that just described might be worked out by the use of Vandermonde's notation, described later in chapter vi, or by the analogous method employed in the theory of the game of solitaire* . I believe that this has not been done, and I do not think it would repay the labour involved. Problems on a Chess-board with Chess-pieces. There are several mathematical recreations with chess-pieces, other than pawns, somewhat similar to those given above. One of these, on the determination of the ways in which eight queens can be placed on a board so that no queen can take any other, is given later in chapter iv. Another, on the path to be followed by a knight which is moved on a chess-

board so that it shall occupy every cell once and only once, is given in chapter vi. Here I will mention one of the simplest of such problems, which is interesting from the fact that it is given in Guarini's manuscript written in 1512; it was quoted by Lucas, but so far as I know has not been otherwise published. Guarini's Problem. On a board of nine cells, such as that drawn below, the two white knights are placed on the two top corner cells * On the theory of the solitaire, see Reiss, 'Beiträge zur Theorie des Solitär-Spiels,' Crelle's Journal, Berlin, 1858, vol. liv, pp. 344–379; and Lucas, vol. i, part v, pp. 89–141. 64 SOME GEOMETRICAL QUESTIONS. [CH. II a C d D B b A c (a, d), and the two black knights on the two bottom corner cells (b, c): the other cells are left vacant. It is required to move the knights so that the white knights shall occupy the cells b and c, while the black shall occupy the cells a and d. The solution is tolerably obvious. First, move the pieces from a to A, from b to B, from c to C, and from d to D. Next, move the pieces from A to d, from B to a, from C to b, and from D to c. The effect of these eight moves is the same as if the original square had been rotated through one right angle. Repeat the above process, that is, move the pieces successively from a to A, from b to B, from c to C, from d to D; from A to d, from B to a, from C to b, and from D to c. The required result is then attained. Geometrical Puzzles with Rods, etc. Another species of geometrical puzzles, to which here I will do no more than allude, are made of steel rods, or of wire, or of wire and string. Numbers of these are often sold in the streets of London for a penny each, and some of them afford ingenious problems in the geometry of position. Most of them could hardly be discussed without the aid of diagrams, but they are inexpensive to construct, and in fact innumerable puzzles on geometry of position can be made with a couple of stout sticks and a ball of string, or even with only a box of matches: several examples are given in the appendix to the fourth volume of the 1723 edition of Ozanam's work. I will mention, as an easy example, analogous to one group of the string puzzles, that any one can take off his waistcoat (which may be unbuttoned) without taking off his coat, and without pulling the waistcoat over the head like a jersey. This last feat may serve to show the difficulty of mentally realizing the effect of geometrical alterations in a figure unless they are of the simplest character. Paradromic Rings. The fact just stated is illustrated by the familiar experiment of making paradromic rings by cutting a paper CH. II] PARADROMIC RINGS. 65 ring prepared in the following manner. Take a strip of paper or piece of tape, say, for convenience, an inch or two wide and at least nine or ten inches long, rule a line in the middle down the length AB of the strip, gum one end over the other end B, and we get a ring like a section of a cylinder. If this ring is cut by a pair of scissors along the ruled line we obtain two rings exactly like the first, except that they are only half the width. Next suppose that the end A is twisted through two right angles before it is gummed to B (the result of which is that the back of the strip at A is gummed over the

front of the strip at B), then a cut along the line will produce only one ring. Next suppose that the end A is twisted once completely round (i.e. through four right angles) before it is gummed to B, then a similar cut produces two interlaced rings. If any of my readers think that these results could be predicted off-hand, it may be interesting to them to see if they can predict correctly the effect of again cutting the rings formed in the second and third experiments down their middle lines in a manner similar to that above described. The theory is due to J.B. Listing* who discussed the case when the end A receives m half-twists, that is, is twisted through mπ, before it is gummed to B. If m is even we obtain a surface which has two sides and two edges, which are termed paradromic. If the ring is cut along a line midway between the edges, we obtain two rings, each of which has m half-twists, and which are linked together 1 2m times. If m is odd we obtain a surface having only one side and one edge. If this ring is cut along its mid-line, we obtain only one ring, but it has 2m half-twists, and if m is greater than unity it is knotted. * Vorstudien zur Topologie, Die Studien, Göttingen, 1847, part x. CHAPTER III. SOME MECHANICAL QUESTIONS. I proceed now to enumerate a few questions connected with mechanics which lead to results that seem to me interesting from a historical point of view or paradoxical. Problems in mechanics generally involve more difficulties than problems in arithmetic, algebra, or geometry, and the explanations of some phenomena—such as those connected with the flight of birds—are still incomplete, while the explanations of many others of an interesting character are too difficult to find a place in a non-technical work. Here, however, I shall confine myself to questions which, like those treated in the two preceding chapters, are of an elementary, not to say trivial, character; and the conclusions are well-known to mathematicians. I assume that the reader is acquainted with the fundamental ideas of kinematics and dynamics, and is familiar with the three Newtonian laws; namely, first that a body will continue in its state of rest or of uniform motion in a straight line unless compelled to change that state by some external force: second, that the change of momentum per unit of time is proportional to the external force and takes place in the direction of it: and third, that the action of one body on another is equal in magnitude but opposite in direction to the reaction of the second body on the first. The first and second laws state the principles required for solving any question on the motion of a particle under the action of given forces. The third law supplies the additional principle required for the solution of problems in which two or more particles influence one another. 66 CH. III] ZENO'S PARADOXES.. 67 Motion. The difficulties connected with the idea of motion have been for a long time a favourite subject for paradoxes, some of which bring us into the realm of the philosophy of mathematics. Zeno's Paradoxes on Motion. One of the earliest of these is the remark of Zeno to the effect that since an arrow cannot move where it is not, and since also it cannot move where it is (i.e. in

the space it exactly fills), it follows that it cannot move at all. The answer that the very idea of the motion of the arrow implies the passage from where it is to where it is not was rejected by Zeno, who seems to have thought that the appearance of motion of a body was a phenomenon caused by the successive appearances of the body at rest but in different positions. Zeno also asserted that the idea of motion was itself inconceivable, for what moves must reach the middle of its course before it reaches the end. Hence the assumption of motion presupposes another motion, and that in turn another, and so ad infinitum. His objection was in fact analogous to the biological difficulty expressed by Swift:— "So naturalists observe, a flea hath smaller fleas that on him prey. And these have smaller fleas to bite 'em. And so proceed ad infinitum." Or as De Morgan preferred to put it "Great fleas have little fleas upon their backs to bite 'em, And little fleas have lesser fleas, and so ad infinitum. And the great fleas themselves, in turn, have greater fleas to go on; While these have greater still, and greater still, and so on." Achilles and the Tortoise. Zeno's paradox about Achilles and the tortoise is known even more widely. The assertion was that if Achilles ran ten times as fast as a tortoise, yet if the tortoise had (say) 1000 yards start it could never be overtaken. To establish this, Zeno argued that when Achilles had gone the 1000 yards, the tortoise would still be 100 yards in front of him; by the time he had covered these 100 yards, it would still be 10 yards in front of him; and so on for ever. Thus Achilles would get nearer and nearer to the tortoise but would never overtake it. Zeno regarded this as confirming his view that the popular idea of motion is self-contradictory. 68 MECHANICAL RECREATIONS. [CH. III Zeno's Paradox on Time. The fallacy of Achilles and the Tortoise is usually explained by saying that though the time required to overtake the tortoise can be divided into an infinite number of intervals, as stated in the argument, yet these intervals get smaller and smaller in geometrical progression, and the sum of them all is a finite time: after the lapse of that time Achilles would be in front of the tortoise. Probably Zeno would have replied that this explanation rests on the assumption that space and time are infinitely divisible, propositions which he would not admit. He seems further to have contended that while, to an accurate thinker, the notion of the infinite divisibility of time was impossible, it was equally impossible to think of a minimum measure of time. For suppose, he argued, that τ is the smallest conceivable interval, and suppose that three horizontal lines composed of three consecutive spans abc, a ' b ' c ' , a ''b ''c '' are placed so that aa'a '' , bb' b '' , cc' c '' are vertically over one another. Imagine the second line moved as a whole one span to the right in the time τ , and simultaneously the third line moved as a whole one span to the left. Then b, a ' , c '' will be vertically over one another. And in this duration τ (which by hypothesis is indivisible) c ' must have passed vertically over a ''. Hence the duration is divisible, contrary to the hypothesis. The Paradox of Tristram Shandy. Mr Russell has enunciated* a

paradox somewhat similar to that of Achilles and the Tortoise, save that the intervals of time considered get longer and longer during the course of events. Tristram Shandy, as we know, took two years writing the history of the first two days of his life, and lamented that, at this rate, material would accumulate faster than he could deal with it, so that he could never come to an end, however long he lived. But had he lived long enough, and not wearied of his task, then, even if his life had continued as eventfully as it began, no part of his biography would have remained unwritten. For if he wrote the events of the first day in the first year, he would write the events of the nth day in the nth year, hence in time the events of any assigned day would be written, and therefore no part of his biography would remain unwritten. This argument might be put in the form of a demonstration that the part of a magnitude may be equal to the whole of it. Questions, such as those given above, which are concerned with the continuity and extent of space and time involve difficulties of a * B.A.W. Russell, Principles of Mathematics, Cambridge, 1903, vol. i, p. 358. CH. III] ANGULAR MOTION. 69 high order. Angular Motion. A non-mathematician finds additional difficulties in the idea of angular motion. For instance, here is a well-known proposition on motion in an equiangular spiral (of which the result is true on the ordinary conventions of mathematics) which shows that a body, moving with uniform velocity and as slowly as we please, may in a finite time whirl round a fixed point an infinite number of times. The equiangular spiral is the trace of a point P, which moves along a line OP, the line OP turning round a fixed point O with uniform angular velocity while the distance of P from O decreases with the time in geometrical progression. If the radius vector rotates through four right angles we have one convolution of the curve. All convolutions are similar, and the length of each convolution is a constant fraction, say 1/nth, that of the convolution immediately outside it. Inside any given convolution, there are an infinite number of convolutions which get smaller and smaller as we get nearer the pole. Now suppose a point Q to move uniformly along the spiral from any point towards the pole. If it covers the first convolution in a seconds, it will cover the next in a/n seconds, the next in a/n2 seconds, and so on, and will finally reach the pole in (a+a/n+a/n2 +a/n3 +· · ·) seconds, that is, in an/(n−1) seconds. The velocity is uniform, and yet in a finite time, Q will have traversed an infinite number of convolutions and therefore have circled round the pole an infinite number of times* . Simple Relative Motion. Even if the philosophical difficulties suggested by Zeno are settled or evaded, the mere idea of relative motion has been often found to present difficulties, and Zeno himself failed to explain a simple phenomenon involving the principle. As one of the easiest examples of this kind, I may quote the common question of how many trains going from B to A a passenger from A to B would meet and pass on his way, assuming that the journey either way takes 4 1 2 hours and that the trains start from each end every hour. The answer is 9. Or again this: Take two

pennies, face upwards on a table and edges in contact. Suppose that one is fixed and that the other rolls on it without slipping, making one complete revolution round it and returning to its initial position. How many revolutions round its own centre has the rolling coin made? The answer is 2. * The proposition is put in this form in J. Richard's Philosophie des mathématiques, Paris, 1903, pp. 119–120. 70 MECHANICAL RECREATIONS. [CH. III Laws of Motion. I proceed next to make a few remarks on points connected with the laws of motion. The first law of motion is often said to define force, but it is in only a qualified sense that this is true. Probably the meaning of the law is best expressed in Clifford's phrase, that force is "the description of a certain kind of motion"—in other words it is not an entity but merely a convenient way of stating, without circumlocution, that a certain kind of motion is observed. It is not difficult to show that any other interpretation lands us in difficulties. Thus some authors use the law to justify a definition that force is that which moves a body or changes its motion; yet the same writers speak of a steam-engine moving a train. It would seem then that, according to them, a steam-engine is a force. That such statements are current may be fairly reckoned among mechanical paradoxes. The idea of force is difficult to grasp. How many people, for instance, could predict correctly what would happen in a question as simple as the following? A rope (whose weight may be neglected) hangs over a smooth pulley; it has one end fastened to a weight of 10 stone, and the other end to a sailor of weight 10 stone, the sailor and the weight hanging in the air. The sailor begins to climb up the rope; will the weight move at all; and, if so, will it rise or fall? It will be noted that in the first law of motion it is asserted that, unless acted on by an external force, a body in motion continues to move (i) with uniform velocity, and (ii) in a straight line. The tendency of a body to continue in its state of rest or of uniform motion is called its inertia. This tendency may be used to explain various common phenomena and experiments. Thus, if a number of dominoes or draughts are arranged in a vertical pile, a sharp horizontal blow on one of those near the bottom will send it out of the pile, and those above will merely drop down to take its place—in fact they have not time to change their relative positions before there is sufficient space for them to drop vertically as if they were a solid body. This also is the principle on which depends the successful playing of "Aunt Sally," and the performance of numerous tricks, described in collections of mathematical puzzles* . * See Les récréations scientifiques by G. Tissandier, where several ingenious illustrations of inertia are given. CH. III] LAWS OF MOTION. 71 The statement about inertia in the first law may be taken to imply that a body set in rotation about a principal axis passing through its centre of mass will continue to move with a uniform angular velocity and to keep its axis of rotation fixed in direction. The former of these statements is the assumption on which our measurement of time is based as mentioned below in chapter xiii. The latter assists us to explain the motion of a projectile in a resisting

fluid. It affords the explanation of why the barrel of a rifle is grooved; and why, similarly, anyone who has to throw a flat body of irregular shape (such as a card) in a given direction usually gives it a rapid rotatory motion about a principal axis. Elegant illustrations of the fact just mentioned are afforded by a good many of the tricks of acrobats, though the full explanation of most of them also introduces other considerations. Thus when some few years ago the Japanese village at Knightsbridge was one of the shows of London, there were some acrobats there who tossed on to the top surface of an umbrella a penny so that it alighted on its edge, and then, by turning round the stick of the umbrella rapidly, the coin was caused to rotate, but as the umbrella moved away underneath it the coin remained apparently stationary and standing upright, while by diminishing or increasing the angular velocity of the umbrella the penny was caused to run forwards or backwards. This is not a difficult trick to execute. The tendency of a body in motion to continue to move in a straight line is sometimes called its centrifugal force. Thus, if a train is running round a curve, it tends to move in a straight line, and is constrained only by the pressure of the rails to move in the required direction. Hence it presses on the outer rail of the curve. This pressure can be diminished to some extent both by raising the outer rail, and by putting a guard rail, parallel and close to the inner rail, against which the wheels on that side also will press. An illustration of this fact occurred in a little known incident of the American civil war* . In the spring of 1862 a party of volunteers from the North made their way to the rear of the Southern armies and seized a train, intending to destroy, as they passed along it, the railway which was the main line of communication between various confederate corps and their base of operations. They were however detected and pursued. To save themselves, they stopped on a sharp curve and tore * Capturing a Locomotive by W. Pittenger, London, 1882, p. 104. 72 MECHANICAL RECREATIONS. [CH. III up some rails so as to throw the engine which was following them off the line. Unluckily for themselves they were ignorant of dynamics and tore up the inner rails of the curve, an operation which did not incommode their pursuers. The second law gives us the means of measuring mass, force, and therefore work. A given agent in a given time can do only a definite amount of work. This is illustrated by the fact that although, by means of a rigid lever and a fixed fulcrum, any force however small may be caused to move any mass however large, yet what is gained in power is lost in speed—as the popular phrase runs. Montucla* inserted a striking illustration of this principle founded on the well-known story of Archimedes who is said to have declared to Hiero that, were he but given a fixed fulcrum, he could move the world. Montucla calculated the mass of the earth and, assuming that a man could work incessantly at the rate of 116 foot-lbs. per second, which is a very high estimate, he found that it would take over three billion centuries, i.e. 3 × 1014 years, before a mass equal to that of the earth was moved as much

as one inch against gravity at the surface of the earth: to move it one inch along a horizonal plane would take about 74000 centuries. Stability of Equilibrium. It is known to all those who have read the elements of mechanics that the centre of gravity of a body, which is resting in equilibrium under its own weight, must be vertically above its base: also, speaking generally, we may say that, if every small displacement has the effect of raising the centre of gravity, then the equilibrium is stable, that is, the body when left to itself will return to its original position; but, if a displacement has the effect of lowering the centre of gravity, then for that displacement the equilibrium is unstable; while, if every displacement does not alter the height above some fixed plane of the centre of gravity, then the equilibrium is neutral. In other words, if in order to cause a displacement work has to be done against the forces acting on the body, then for that displacement the equilibrium is stable, while if the forces do work the equilibrium is unstable. A good many of the simpler mechanical toys and tricks afford illustrations of this principle. * Ozanam, 1803 edition, vol. ii, p. 18; 1840 edition, p. 202. CH. III] MAGIC BOTTLES. 73 Magic Bottles* . Among the most common of such toys are the small bottles—trays of which may be seen any day in the streets of London—which keep always upright, and cannot be upset until their owner orders them to lie down. Such a bottle is made of thin glass or varnished paper fixed to the plane surface of a solid hemisphere or smaller segment of a sphere. Now the distance of the centre of gravity of a homogeneous hemisphere from the centre of the sphere is threeeighths of the radius, and the mass of the glass or varnished paper is so small compared with the mass of the lead base that the centre of gravity of the whole bottle is still within the hemisphere. Let us denote the centre of the hemisphere by C, and the centre of gravity of the bottle by G. If such a bottle is placed with the hemisphere resting on a horizontal plane and GC vertical, any small displacement on the plane will tend to raise G, and thus the equilibrium is stable. This may be seen also from the fact that when slightly displaced there is brought into play a couple, of which one force is the reaction of the table passing through C and acting vertically upward, and the other the weight of the bottle acting vertically downward at G. If G is below C, this couple tends to restore the bottle to its original position. If there is dropped into the bottle a shot or nail so heavy as to raise the centre of gravity of the whole above C, then the equilibrium is unstable, and, if any small displacement is given, the bottle falls over on to its side. Montucla says that in his time it was not uncommon to see boxes of tin soldiers mounted on lead hemispheres, and when the lid of the box was taken off the whole regiment sprang to attention. In a similar way we may explain how to balance a pencil in a vertical position, with its point resting on the top of one’s finger, an experiment which is described in nearly every book of puzzles† . This is effected by taking a penknife, of which one blade is opened through an angle of (say) 120◦ , and sticking the blade in the pencil so that the handle of the

penknife is below the finger. The centre of gravity is thus brought below the point of support, and a small displacement given to the pencil will raise the centre of gravity of the whole: thus the equilibrium is stable. * Ozanam, 1803 edition, vol. ii, p. 15; 1840 edition, p. 201. † Ex. gr. Oughtred, Mathematical Recreations, p. 24; Ozanam, 1803 edition, vol. ii, p. 14; 1840 edition, p. 200. 74 MECHANICAL RECREATIONS. [CH. III Other similar tricks are the suspension of a bucket over the edge of a table by a couple of sticks, and the balancing of a coin on the edge of a wine-glass by the aid of a couple of forks*—the sticks or forks being so placed that the centre of gravity of the whole is vertically below the point of support and its depth below it a maximum. The toy representing a horseman, whose motion continually brings him over the edge of a table into a position which seems to ensure immediate destruction, is constructed in somewhat the same way. A wire has one end fixed to the feet of the rider; the wire is curved downwards and backwards, and at the other end is fixed a weight. When the horse is placed so that his hind legs are near the edge of the table and his forefeet over the edge, the weight is under his hind feet. Thus the whole toy forms a pendulum with a curved instead of a straight rod. Hence the farther it swings over the table, the higher is the centre of gravity raised, and thus the toy tends to return to its original position of equilibrium. An elegant modification of the prancing horse was brought out at Paris in 1890 in the shape of a toy made of tin and in the figure of a man† . The legs are pivoted so as to be movable about the thighs, but with a wire check to prevent too long a step, and the hands are fastened to the top of a T -shaped wire weighted at its ends. If the figure is placed on a narrow sloping plank or strip of wood passing between the legs of the T , then owing to the T -shaped wire any lateral displacement of the figure will raise its centre of gravity, and thus for any such displacement the equilibrium is stable. Hence, if a slight lateral disturbance is given, the figure will oscillate and will rest alternately on each foot: when it is supported by one foot the other foot under its own weight moves forwards, and thus the figure will walk down the plank though with a slight reeling motion. Shortly after the publication of the third edition of this book an improved form of this toy, in the shape of a walking elephant made in heavy metal, was issued in England, and probably in that form it is now familiar to all who are interested in noticing street toys. Columbus's Egg. The toy known as Columbus's egg depends on the same principle as the magic bottle, though it leads to the converse result. The shell of the egg is made of tin and cannot be opened. Inside * Oughtred, p. 30; Ozanam, 1803 edition, vol. ii, p. 12; 1840 edition, p. 199. † La Nature, Paris, March, 1891. CH. III] CONES RUNNING UP HILL. 75 it and fastened to its base is a hollow truncated tin cone, and there is also a loose marble inside the shell. If the egg is held properly, the marble runs inside the cone and the egg will stand on its base, but so long as the marble is outside the cone, the egg cannot be made to stand on its base. Cones running up hill* . The experiment

to make a double cone run up hill depends on the same principle as the toys above described; namely, on the tendency of a body to take a position so that its centre of gravity is as low as possible. In this case it produces the optical effect of a body moving by itself up a hill. Usually the experiment is performed as follows. Arrange two sticks in the shape of a W , with the apex on a table and the two upper ends resting on the top edge of a book placed on the table. Take two equal cones fixed base to base, and place them with the curved surfaces resting on the sticks near the apex of the W , the common axis of the cones being horizontal and parallel to the edge of the book. Then, if properly arranged, the cones will run up the plane formed by the sticks. The explanation is obvious. The centre of gravity of the cones moves in the vertical plane midway between the two sticks and it occupies a lower position as the points of contact on the sticks get farther apart. Hence as the cone rolls up the sticks its centre of gravity descends. Perpetual Motion. The idea of making a machine which once set going would continue to go for ever by itself has been the ignis fatuus of self-taught mechanicians in much the same way as the quadrature of the circle has been of self-taught geometricians. Now the obvious meaning of the third law of motion is that a force is only one aspect of a stress, and that whenever a force is caused another equal and opposite one is brought also into existence—though it may act upon a different body, and thus be immaterial for the particular problem considered. The law however is capable of another interpretation† , namely, that the rate at which an agent does work (that is, its action) is equal to the rate at which work is done against it (that is, its reaction). If it is allowable to include in the reaction the rate at which kinetic energy is being produced, and if work is taken to include * Ozanam, 1803 edition, vol. ii, p. 49; 1840 edition, p. 216. † Newton's Principia, last paragraph of the Scholium to the Laws of Motion. 76 MECHANICAL RECREATIONS. [CH. III that done against molecular forces, then it follows from this interpretation that the work done by an agent on a system is equivalent to the total increase of energy, that is, the power of doing work. Hence in an isolated system the total amount of energy is constant. If this is granted, then since friction and some molecular dissipation of energy cannot be wholly prevented, it must be impossible to construct in an isolated system a machine capable of perpetual motion. I do not propose to describe in detail the various machines for producing perpetual motion which have been suggested, but I may add that a number of them are equivalent essentially to the one of which a section is represented in the accompanying figure. C It consists of two concentric vertical wheels in the same plane, and mounted on a horizontal axle through their centre, C. The space between the wheels is divided into compartments by spokes inclined at a constant angle to the radii to the points whence they are drawn, and each compartment contains a heavy bullet. Apart from these bullets, the wheels would be in equilibrium. Each bullet tends to turn the wheels round their axle, and

the moment which measures this tendency is the product of the weight of the bullet and its distance from the vertical through C. The idea of the constructors of such machines was that, as the bullet in any compartment would roll under gravity to the lowest point of the compartment, the bullets on the right-hand side of the diagram would be farther from the vertical through C than those on the left. Hence the sum of the moments of the weights of the bullets on the CH. III] PERPETUAL MOTION. 77 right would be greater than the sum of the moments of those on the left. Thus the wheels would turn continually in the same direction as the hands of a watch. The fallacy in the argument is obvious. Another large group of machines for producing perpetual motion depended on the use of a magnet to raise a mass which was then allowed to fall under gravity. Thus, if the bob of a simple pendulum was made of iron, it was thought that magnets fixed near the highest points which were reached by the bob in the swing of the pendulum would draw the bob up to the same height in each swing and thus give perpetual motion. Of course it is only in isolated systems that the total amount of energy is constant, and, if a source of external energy can be obtained from which energy is continually introduced into the system, perpetual motion is, in a sense, possible; though even here materials would ultimately wear out. The solar heat and the tides are among the most obvious of such sources. There was at Paris in the latter half of the eighteenth century a clock which was an ingenious illustration of such perpetual motion* . The energy which was stored up in it to maintain the motion of the pendulum was provided by the expansion of a silver rod. This expansion was caused by the daily rise of temperature, and by means of a train of levers it wound up the clock. There was a disconnecting apparatus, so that the contraction due to a fall of temperature produced no effect, and there was a similar arrangement to prevent overwinding. I believe that a rise of eight or nine degrees Fahrenheit was sufficient to wind up the clock for twenty-four hours. I have in my possession a watch, which produces the same effect by somewhat different means. Inside the case is a steel weight, and if the watch is carried in a pocket this weight rises and falls at every step one takes, somewhat after the manner of a pedometer. The weight is raised by the action of the person who has it in his pocket in taking a step, and in falling it winds up the spring of the watch. On the face is a small dial showing the number of hours for which the watch is wound up. As soon as the hand of this dial points to fifty-six hours, the train of levers which winds up the watch disconnects automatically, so as to prevent overwinding the spring, and it reconnects again as soon as the watch has run down eight hours. The watch is an excellent timekeeper, and a walk of about a couple of miles is sufficient to wind it * Ozanam, 1803 edition, vol. ii, p. 105; 1840 edition, p. 238. 78 MECHANICAL RECREATIONS. [CH. III up for twenty-four hours. Models. I may add here the observation, which is well known to mathematicians, but is a perpetual source of disappointment to ignorant inventors, that it frequently happens that an

accurate model of a machine will work satisfactorily while the machine itself will not do so. One reason for this is as follows. If all the parts of a model are magnified in the same proportion, say m, and if thereby a line in it is increased in the ratio m : 1, then the areas and volumes in it will be increased respectively in the ratios m2 : 1 and m3 : 1. For example, if the side of a cube is doubled then a face of it will be increased in the ratio 4 : 1 and its volume will be increased in the ratio 8 : 1. Now if all the linear dimensions are increased m times, then some of the forces that act on a machine (such, for example, as the weight of part of it) will be increased m3 times, while others which depend on area (such as the sustaining power of a beam) will be increased only m2 times. Hence the forces that act on the machine and are brought into play by the various parts may be altered in different proportions, and thus the machine may be incapable of producing results similar to those which can be produced by the model. The same argument has been adduced in the case of animal life to explain why very large specimens of any particular breed or species are usually weak. For example, if the linear dimensions of a bird were increased n times, the work necessary to give the power of flight would have to be increased no less than n 7 times* . Again, if the linear dimensions of a man of height 5 ft. 10 in. were increased by one-seventh his height would become 6 ft. 8 in., but his weight would be increased in the ratio 512 : 343 (i.e. about half as much again), while the cross sections of his legs, which would have to bear this weight, would be increased only in the ratio 64 : 49; thus in some respects he would be less efficient than before. Of course the increased dimensions, length of limb, or size of muscle might be of greater advantage than the relative loss of strength; hence the problem of what are the most efficient proportions is not simple, but the above argument will serve to illustrate the fact that the working of a machine may not be similar to that of a model of it. * Helmholtz, Gesammelte Abhandlungen, Leipzig, 1881, vol. i, p. 165. CH. III] SAILING QUICKER THAN THE WIND. 79 Leaving now these elementary considerations I pass on to some other mechanical questions. Sailing quicker than the Wind. As a kinematical paradox I may allude to the possibility of sailing quicker than the wind blows, a fact which strikes many people as curious. The explanation* depends on the consideration of the velocity of the wind relative to the boat. Perhaps, however, a non-mathematician will find the solution simplified if I consider first the effect of the windpressure on the back of the sail which drives the boat forward, and second the resistance to motion caused by the sail being forced through the air. When the wind is blowing against a plane sail the resultant pressure of the wind on the sail may be resolved into two components, one perpendicular to the sail (but which in general is not a function only of the component velocity in that direction, though it vanishes when that component vanishes) and the other parallel to its plane. The latter of these has no effect on the motion of the ship. The component perpendicular to the

sail tends to move the ship in that direction. This pressure, normal to the sail, may be resolved again into two components, one in the direction of the keel of the boat, the other in the direction of the beam of the boat. The former component drives the boat forward, the latter to leeward. It is the object of a boat-builder to construct the boat on lines so that the resistance of the water to motion forward shall be as small as possible, and the resistance to motion in a perpendicular direction (i.e. to leeward) shall be as large as possible; and I will assume for the moment that the former of these resistances may be neglected, and that the latter is so large as to render motion in that direction impossible. Now, as the boat moves forward, the pressure of the air on the front of the sail will tend to stop the motion. As long as its component normal to the sail is less than the pressure of the wind behind the sail and normal to it, the resultant of the two will be a force behind the sail and normal to it which tends to drive the boat forwards. But as the velocity of the boat increases, a time will arrive when the pressure of the wind is only just able to balance the resisting force which is caused by the sail moving through the air. The velocity of the boat will not * Ozanam, 1803 edition, vol. iii, pp. 359, 367; 1840 edition, pp. 540, 543. 80 MECHANICAL RECREATIONS. [CH. III BR S L A W increase beyond this, and the motion will be then what mathematicians describe as “steady.” In the accompanying figure, let BAR represent the keel of a boat, B being the bow, and let SAL represent the sail. Suppose that the wind is blowing in the direction WA with a velocity u; and that this direction makes an angle θ with the keel, i.e. angle WAR = θ. Suppose that the sail is set so as to make an angle α with the keel, i.e. angle BAS = α, and therefore angle WAL = θ + α. Suppose finally that v is the velocity of the boat in the direction AB. I have already shown that the solution of the problem depends on the relative directions and velocities of the wind and the boat; hence to find the result reduce the boat to rest by impressing on it a velocity v in the direction BA. The resultant velocity of v parallel to BA and of u parallel to WA will be parallel to SL, if v sin α = u sin(θ + α); and in this case the resultant pressure perpendicular to the sail vanishes. Thus, for steady motion we have v sin α = u sin(θ + α). Hence, whenever sin(θ + α) > sin α, we have v > u. Suppose, to take one instance, the sail to be fixed, that is, suppose α to be a constant. Then v is a maximum if θ + α = 1 2 π, that is, if θ is equal to the complement of α. In this case we have v = u cosec α, and therefore v is greater than u. Hence, if the wind makes the same angle α abaft the beam that the sail makes with the keel, the velocity of the boat will be greater than the velocity of the wind. Next, suppose that the boat is running close to the wind, so that the wind is before the beam (see figure below), then in the same way as before we have v sin α = u sin(θ + α), or v sin α = u sin ϕ, where CH. III] BOAT MOVED BY A ROPE.. 81 ϕ = angle WAS = π − θ − α. Hence v = u sin ϕ cosec α. Let w be the component velocity of the boat in the teeth of the wind, that is, in the direction AW. Then we have w = v cos BAW = v cos(α + ϕ) = u sin ϕ

cosec α cos(α + ϕ). If α is constant, this is a maximum when ϕ = 1 4 π − 1 2 α; and, if ϕ has this value, then w = 1 2 u(cosec α − 1). This formula shows that w is greater than u, if sin α < 1 3 . Thus, if the sails can be set so that α is less than sin−1 1 3 , that is, rather less than 19◦29′ , and if the wind has the direction above assigned, then the component velocity of the boat in the face of the wind is greater than the velocity of the wind. The above theory is curious, but it must be remembered that in practice considerable allowance has to be made for the fact that no boat for use on water can be constructed in which the resistance to BR S L A W motion in the direction of the keel can be wholly neglected, or which would not drift slightly to leeward if the wind was not dead astern. Still this makes less difference than might be thought by a landsman. In the case of boats sailing on smooth ice the assumptions made are substantially correct, and the practical results are said to agree closely with the theory. Boat moved by a Rope. There is a form of boat-racing, occasionally used at regattas, which affords a somewhat curious illustration of certain mechanical principles. The only thing supplied to the crew 82 MECHANICAL RECREATIONS. [CH. III is a coil of rope, and they have, without leaving the boat, to propel it from one point to another as rapidly as possible. The motion is given by tying one end of the rope to the after thwart, and giving the other end a series of violent jerks in a direction parallel to the keel. I am told that in still water a pace of two or three miles an hour can be thus attained. The chief cause for this result seems to be that the friction between the boat and the water retards all relative motion, but is not great enough to materially affect motion caused by a sufficiently big impulse. Hence the usual movements of the crew in the boat do not sensibly move the centre of gravity of themselves and the boat, but this does not apply to an impulsive movement, and if the crew in making a jerk move their centre of gravity towards the bow n times more rapidly than it returns after the jerk, then the boat is impelled forwards at least n times more than backwards: hence on the whole the motion is forwards. Motion of Fluids and Motion in Fluids. The theories of motion of fluids and motion in fluids involve considerable difficulties. Here I will mention only one or two instances—mainly illustrations of Hauksbee's Law. Hauksbee's Law. When a fluid is in rapid motion the pressure is less than when it is at rest* . Thus, if a current of air is moving in a tube, the pressure on the sides of the tube is less than when the air is at rest— and the quicker the air moves the smaller is the pressure. This fact was noticed by Hauksbee nearly two centuries ago. In an elastic perfect fluid in which the pressure is proportional to the density, the law connecting the pressure, p, and the steady velocity, v, is p = Πα −v 2 where Π and α are constants: the establishment of corresponding formula for gases where the pressure is proportional to a power of the density presents no difficulty. This principle is illustrated by a twopenny toy, on sale in most toy-shops, called the pneumatic mystery. It consists of a tube, with a cup-shaped end in which rests a wooden ball.

If the tube is held in a vertical position, with the mouthpiece at the upper end and the cup at * See Besant, Hydromechanics, Cambridge, 1867, art. 149, where however it is assumed that the pressure is proportional to the density. Hauksbee was the earliest writer who called attention to the problem, but I do not know who first explained the phenomenon; some references to it are given by Willis, Cambridge Philosophical Transactions, 1830, vol. iii, pp. 129–140. CH. III] SPIN ON TENNIS AND CRICKET BALLS.. 83 the lower end, then, if anyone blows hard through the tube and places the ball against the cup, the ball will remain suspended there. The explanation is that the pressure of the air below the ball is so much greater than the pressure of the air in the cup that the ball is held up. The same effect may be produced by fastening to one end of a tube a piece of cardboard having a small hole in it. If a piece of paper is placed over the hole and the experimenter blows through the tube, the paper will not be detached from the card but will bend so as to allow the egress of the air. An exactly similar experiment, described in many text-books on hydromechanics, is made as follows. To one end of a straight tube a plane disc is fitted which is capable of sliding on wires projecting from the end of the tube. If the disc is placed at a small distance from the end, and anyone blows steadily into the tube, the disc will be drawn towards the tube instead of being blown off the wires, and will oscillate about a position near the end of the tube. In the same way we may make a tube by placing two books on a table with their backs parallel and an inch or so apart and laying a sheet of newspaper over them. If anyone blows steadily through the tube so formed, the paper will be sucked in instead of being blown out. The following experiment is explicable by the same argument. On the top of a vertical axis balance a thin horizontal rod. At each end of this rod fasten a small vertical square or sail of thin cardboard—the two sails being in the same plane. If anyone blows close to one of these squares and in a direction parallel to its plane, the square will move towards the side on which one is blowing, and the rod with the two sails will rotate about the axis. The experiments above described can be performed so as to illustrate Hauksbee's Law; but unless care is taken other causes will be also introduced which affect the phenomena: it is however unnecessary for my purpose to go into these details. Cut on a Tennis-Ball. Racquet and tennis players know that if a strong cut is given to a ball it can be made to rebound off a vertical wall and then (without striking the floor or any other wall) return and hit the wall again. This affords another illustration of Hauksbee's Law. The explanation* is that the cut causes the ball to rotate rapidly about an axis * See Magnus on 'Die Abweichung der Geschosse' in the Abhandlungen der 84 MECHANICAL RECREATIONS. [CH. III through its centre of figure, and the friction of the surface of the ball on the air produces a sort of whirlpool. This rotation is in addition to its motion of translation. Suppose the ball to be spherical and rotating about an axis through its centre perpendicular to the plane of the paper in the direction of the arrow-head, and at

the same time moving through still air from left to right parallel to P Q. Any motion of the ball perpendicular to P Q will be produced by the pressure of the air on the surface of the ball, and this pressure will, by Hauksbee's Law, be greatest where the velocity of the air relative to the ball is least, and vice versa. To find the velocity of the air relative to the ball we may reduce the centre of the ball to rest, and suppose a stream of air to impinge on the surface of the ball moving with a velocity equal and opposite to that of the centre of the ball. The air is not frictionless, and therefore the air in contact with the surface of the ball will be set in motion, by the rotation of the ball and will form a sort of whirlpool rotating in the direction of the arrow-head in the figure. To find the actual velocity of this air relative to the ball we must consider how the motion due to the whirlpool is affected by the motion of the stream of air parallel to QP. The air at A in the whirlpool is moving against the stream of air there, and therefore its velocity is retarded: the air at B in the whirlpool is moving in the same direction as the stream of air there, and therefore its velocity is increased. Hence the relative velocity of the air at A is less than that at B, and since the pressure of the air is greatest where the velocity is least, the pressure of the air on the surface of the ball at A is greater than on that at B, Hence the ball is forced by this pressure in the direction from the line P Q, P Q A B which we may suppose to represent the section of the vertical wall in Akademie der Wissenschaften, Berlin, 1852, pp. 1–23; Lord Rayleigh, 'On the irregular flight of a tennis ball,' Messenger of Mathematics, Cambridge, 1878, vol. vii, pp. 14–16. CH. III] FLIGHT OF BIRDS. 85 a racquet-court. In other words, the ball tends to move at right angles to the line in which its centre is moving and in the direction in which the surface of the front of the ball is being carried by the rotation. In the case of a lawn tennis-ball, the shape of the ball is altered by a strong cut, and this introduces additional complications. Spin on a Cricket-Ball. The curl of a cricket-ball in its flight through the air, caused by a spin given by the bowler in delivering the ball, is explained by the same reasoning. Thus suppose the ball is delivered in a direction lying in a vertical plane containing the two middle stumps of the wickets. A spin round a horizontal axis parallel to the crease in a direction which the bowler's umpire would describe as positive, namely, counter clock-wise, will, in consequence of the friction of the air, cause it to drop, and therefore decrease the length of the pitch. A spin in the opposite direction will cause it to rise, and therefore lengthen the pitch. A spin round a vertical axis in the positive direction, as viewed from above, will make it curl sideways in the air to the left, that is, from leg to off. A spin in the opposite direction will make it curl to the right. A spin given to the ball round the direction of motion of the centre of the ball will not sensibly affect the motion through the air, though it would cause the ball, on hitting the ground, to break. Of course these various kinds of spin can be combined. The questions involving the application of Hauksbee's Law are easy as compared with many of the problems in fluid

motion. The analysis required to attack most of these problems is beyond the scope of this book, but one of them may be worth mentioning even though no explanation is given. The Theory of the Flight of Birds. A mechanical problem of great interest is the explanation of the means by which birds are enabled to fly for considerable distances with no (perceptible) motion of the wings. Albatrosses, to take an instance of special difficulty, have been known to follow for some days ships running at the rate of nine or ten knots, and sometimes for considerable periods there is no motion of the wings or body which can be detected, while even if the bird moved its wings it is not easy to understand how it has the muscular energy to propel itself so rapidly and for such a length of time. Of this phenomenon 86 MECHANICAL RECREATIONS. [CH. III various explanations* have been suggested. Notable among these are Mr Maxim's of upward air-currents, Lord Rayleigh's of variations of the wind velocity at different heights above the ground, Dr S.P. Langley's of the incessant occurrence of gusts of wind separated by lulls, and Dr Bryan's of vortices in the atmosphere. It now seems reasonably certain that the second and third of these sources of energy account for at least a portion of the observed phenomena. The effect of the third cause may be partially explained by noting that the centre of gravity of the bird with extended wings is slightly below the aeroplane or wing surface, so that the animal forms a sort of parachute. The effect of a sudden gust of wind upon such a body is that the aeroplane is set in motion more rapidly than the suspended mass, causing the structure to heel over so as to receive the wind on the under surface of the aeroplane, and this lifts the suspended mass giving it an upward velocity. When the wind falls the greater inertia of the mass carries it on upwards causing the aeroplane to again present its under side to the air; and if while the parachute is in this position the wind is still blowing from the side, the suspended mass is again lifted. Thus the more the bird is blown about, the more it rises in the air; actually birds in flight are carried up by a sudden side gust of wind as we should expect from this theory. The fact that the bird is in motion tends also to keep it up, for it has been recently shown that a horizontal plane under the action of gravity falls to the ground more slowly if it is travelling through the air with horizontal velocity than it would do if allowed to fall vertically, hence the bird's forward motion causes it to fall through a smaller height between successive gusts of wind than it would do if it were at rest, Moreover it has been proved experimentally that the horsepower required to support a body in horizontal flight by means of an aeroplane is less for high than for low speeds: hence when a side-wind (that is, a wind at right angles to the bird's course) strikes the bird, the lift is increased in consequence of the bird's forward velocity. Curiosa Physica. When I was writing the first edition of these "Recreations," I put together a chapter, following this one, on "Some Physical Questions," dealing with problems such as, in the Theory of * See G.H. Bryan in the Transactions of the British Association for 1896, vol. lxvi, pp.

726-728. CH. III] CURIOSA PHYSICA. 87 Sound, the explanation of the fact that in some of Captain Parry's experiments the report of a cannon, when fired, travelled so much more rapidly than the sound of the human voice that observers heard the report of the cannon when fired before that of the order to fire it* : in the Kinetic Theory of Gases, the complications in our universe that might be produced by "Maxwell's demon" † : in the Theory of Optics, the explanation of the Japanese "magic mirrors," ‡ which reflect the pattern on the back of the mirror (on which the light does not fall): to which I might add the theory of the "spectrum top," by means of which a white surface, on which some black lines are drawn, can be moved so as to give the impression§ that the lines are coloured (red, green, blue, slate, or drab), and the curious fact that the colours change with the direction of rotation: it has also been recently shown that if two trains of waves, whose lengths are in the ratio m − 1 : m + 1, be superposed, then every mth wave in the system will be big—thus the current opinion that every ninth wave in the open sea is bigger than the other waves may receive scientific confirmation. There is no lack of interesting and curious phenomena in physics, and in some branches, notably in electricity and magnetism, the difficulty is rather one of selection, but I felt that the connection with mathematics was in general either too remote or too technical to justify the insertion of such a collection in a work on elementary mathematical recreations, and therefore I struck out the chapter. I mention the fact now partly to express the hope that some physicist will one day give us a collection of the kind, partly to suggest these questions to those who are interested in such matters. * The fact is well authenticated. Mr Earnshaw (Philosophical Transactions, London, 1860, pp. 133–148) explained it by the acceleration of a wave caused by the formation of a kind of bore, a view accepted by Clerk Maxwell and most physicists, but Sir George Airy thought that the explanation was to be found in physiology; see Airy's Sound, second edition, London, 1871, pp. 141, 142. † See Theory of Heat, by J. Clerk Maxwell, second edition, London, 1872, p. 308. ‡ See a memoir by W.E. Ayrton and J. Perry, Proceedings of the Royal Society of London, part i, 1879, vol. xxviii, pp. 127–148. § See letters from Mr C.E. Benham and others in Nature, 1894–5; and a memoir by Prof. Liveing, Cambridge Philosophical Society, November 26, 1894. CHAPTER IV. SOME MISCELLANEOUS QUESTIONS. I propose to discuss in this chapter the mathematical theory of certain of the more common mathematical amusements and games. Some of these might have been treated in the first two chapters, but, since most of them involve mixed geometry and algebra, it is rather more convenient to deal with them apart from the problems and puzzles which have been described already. This division, however, is by no means well defined, and the arrangement is based on convenience rather than on any logical distinction. The majority of the questions here enumerated have no connection one with another, and I jot them down almost at random. I shall discuss in succession the

Fifteen Puzzle, the Tower of Hanoï, Chinese Rings, the Eight Queens Problem, the Fifteen School-Girls Problem, and some miscellaneous Problems connected with a pack of cards. The Fifteen Puzzle† . Some years ago the so-called fifteen puzzle was on sale in all toy-shops. It consists of a shallow wooden box—one side being marked as the top—in the form of a square, and contains fifteen square blocks or counters numbered 1, 2, 3 . . . up to 15. The box will hold just sixteen such counters, and, as it contains only fifteen, they can be moved about in the box relatively to one another. Initially they are put in the box in any order, but leaving the sixteenth † There are two articles on the subject in the American Journal of Mathematics 1879, vol. ii, by Professors Woolsey Johnson and Story; but the whole theory is deducible immediately from the proposition I give above in the text. 88 CH. IV] THE FIFTEEN PUZZLE. 89 cell or small square empty; the puzzle is to move them so that finally they occupy the position shown in the first of the annexed figures. 12 3 4 5 6 7 8 9 10 11 12 13 14 15 AB CD Bottom of Box Top of Box 214 3 6 5 8 7 10 9 12 11 13 14 15 We may represent the various stages in the game by supposing that the blank space, occupying the sixteenth cell, is moved over the board, ending finally where it started. The route pursued by the blank space may consist partly of tracks followed and again retraced, which have no effect on the arrangement, and partly of closed paths travelled round, which necessarily are cyclical permutations of an odd number of counters. No other motion is possible. Now a cyclical permutation of n letters is equivalent to n−1 simple interchanges; accordingly an odd cyclical permutation is equivalent to an even number of simple interchanges. Hence, if we move the counters so as to bring the blank space back into the sixteenth cell, the new order must differ from the initial order by an even number of simple interchanges. If therefore the order we want to get can be obtained from this initial order only by an odd number of interchanges, the problem is incapable of solution; if it can be obtained by an even number, the problem is possible. Thus the order in the second of the diagrams given on the current page is deducible from that in the first diagram by six interchanges; namely, by interchanging the counters 1 and 2, 3 and 4, 5 and 6, 7 and 8, 9 and 10, 11 and 12. Hence the one can be deduced from the other by moving the counters about in the box. If however in the second diagram the order of the last three counters had been 13, 15, 14, then it would have required seven interchanges of 90 MISCELLANEOUS MATHEMATICAL RECREATIONS. [CH. IV counters to bring them into the order given in the first diagram. Hence in this case the problem would be insoluble. The easiest way of finding the number of simple interchanges necessary in order to obtain one given arrangement from another is to make the transformation by a series of cycles. For example, suppose that we take the counters in the box in any definite order, such as taking the successive rows from left to right, and suppose the original order and the final order to be respectively 1, 13, 2, 3, 5, 7, 12, 8, 15, 6, 9, 4, 11, 10, 14, and 11, 2, 3, 4, 5,

6, 7, 1, 9, 10, 13, 12, 8, 14, 15. We can deduce the second order from the first by 12 simple interchanges. The simplest way of seeing this is to arrange the process in three separate cycles as follows:— 1, 11, 8 ; 13, 2, 3, 4, 12, 7, 6, 10, 14, 15, 9 ; 5. 11, 8, 1 ; 2, 3, 4, 12, 7, 6, 10, 14, 15, 9, 13 ; 5. Thus, if in the first row of figures 11 is substituted for 1, then 8 for 11, then 1 for 8, we have made a cyclical interchange of 3 numbers, which is equivalent to 2 simple interchanges (namely, interchanging 1 and 11, and then 1 and 8). Thus the whole process is equivalent to one cyclical interchange of 3 numbers, another of 11 numbers, and another of 1 number. Hence it is equivalent to (2 + 10 + 0) simple interchanges. This is an even number, and thus one of these orders can be deduced from the other by moving the counters about in the box. It is obvious that, if the initial order is the same as the required order except that the last three counters are in the order 15, 14, 13, it would require one interchange to put them in the order 13, 14, 15; hence the problem is insoluble. If however the box is turned through a right angle, so as to make AD the top, this rotation will be equivalent to 13 simple interchanges. For, if we keep the sixteenth square always blank, then such a rotation would change any order such as 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, to 13, 9, 5, 1, 14, 10, 6, 2, 15, 11, 7, 3, 12, 8, 4, which is equivalent to 13 simple interchanges. Hence it will change the arrangement from one in which a solution is impossible to one where it is possible, and vice versa. CH. IV] THE TOWER OF HANOÏ. 91 Again, even if the initial order is one which makes a solution impossible, yet if the first cell and not the last is left blank it will be possible to arrange the fifteen counters in their natural order. For, if we represent the blank cell by b, this will be equivalent to changing the order 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, b, b, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 : this is a cyclical interchange of 16 things and therefore is equivalent to 15 simple interchanges. Hence it will change the arrangement from one in which a solution is impossible to one where it is possible, and vice versa. It is evident that the above principles are applicable equally to a rectangular box containing mn cells or spaces and mn − 1 counters which are numbered. Of course m may be equal to n. If such a box is turned through a right angle, and m and n are both even, it will be equivalent to mn − 3 simple interchanges—and thus will change an impossible position to a possible one, and vice versa—but unless both m and n are even the rotation is equivalent to only an even number of interchanges. Similarly, if either m or n is even, and it is impossible to solve the problem when the last cell is left blank, then it will be possible to solve it by leaving the first cell blank. The problem may be made more difficult by limiting the possible movements by fixing bars inside the box which will prevent the movement of a counter transverse to their directions. We can conceive also of a similar cubical puzzle, but we could not work it practically except by sections. The Tower of Hanoï. I may mention next the ingenious puzzle known as the Tower of Hanoï. It was brought out in 1883 by M. Claus

(Lucas). It consists of three pegs fastened to a stand, and of eight circular discs of wood or cardboard each of which has a hole in the middle so that a peg can be put through it. These discs are of different radii, and initially they are placed all on one peg, so that the biggest is at the bottom, and the radii of the successive discs decrease as we ascend: thus the smallest disc is at the top. This arrangement is called the Tower. The problem is to shift the discs from one peg to another in such a way that a disc shall never rest on one smaller than itself, and 92 MISCELLANEOUS MATHEMATICAL RECREATIONS. [CH. IV finally to transfer the tower (i.e. all the discs in their proper order) from the peg on which they initially rested to one of the other pegs. The method of effecting this is as follows. (i) If initially there are n discs on the peg A, the first operation is to transfer gradually the top n − 1 discs from the peg A to the peg B, leaving the peg C vacant: suppose that this requires x separate transfers. (ii) Next, move the bottom disc to the peg C. (iii) Then, reversing the first process, transfer gradually the n − 1 discs from B to C, which will necessitate x transfers. Hence, if it requires x transfers of simple discs to move a tower of n − 1 discs, then it will require 2x + 1 separate transfers of single discs to move a tower of n discs. Now with 2 discs it requires 3 transfers, i.e. 2 2−1 transfers; hence with 3 discs the number of transfers required will be 2(22 −1) + 1, that is, 2 3 −1. Proceeding in this way we see that with a tower of n discs it will require 2 n − 1 transfers of single discs to effect the complete transfer. Thus the eight discs of the puzzle will require 255 single transfers. The result can be also obtained by the theory of finite differences. It will be noticed that every alternate move consists of a transfer of the smallest disc from one peg to another, the pegs being taken in cyclical order. M. De Parville gives an account of the origin of the toy which is a sufficiently pretty conceit to deserve repetition* . In the great temple at Benares, says he, beneath the dome which marks the centre of the world, rests a brass-plate in which are fixed three diamond needles, each a cubit high and as thick as the body of a bee. On one of these needles, at the creation, God placed sixty-four discs of pure gold, the largest disc resting on the brass plate, and the others getting smaller and smaller up to the top one. This is the Tower of Bramah. Day and night unceasingly the priests transfer the discs from one diamond needle to another according to the fixed and immutable laws of Bramah, which require that the priest must not move more than one disc at a time and that he must place this disc on a needle so that there is no smaller disc below it. When the sixty-four discs shall have been thus transferred from the needle on which at the creation God placed them to one of the other needles, tower, temple, and Brahmins alike will crumble into dust, and with a thunder-clap the world will vanish. Would that English writers were in the habit of inventing equally interesting origins for the puzzles they produce! * La Nature, Paris, 1884, part i, pp. 285–286. CH. IV] CHINESE RINGS. 93 The number of separate transfers of single discs which the Brahmins must make to effect the transfer of the

tower is 2 64 − 1, that is, is 18, 446744, 073709, 551615: a number which, even if the priests never made a mistake, would require many thousands of millions of years to carry out. Chinese Rings* . A somewhat more elaborate toy, known as Chinese Rings, which is on sale in most English toy-shops, is represented in the accompanying figure. It consists of a number of rings hung upon a bar in such a manner that the ring at one end (say A) can be taken off or put on the bar at pleasure; but any other ring can be taken off or put on only when the one next to it towards A is on, and all the rest towards A are off the bar. The order of the rings cannot be changed. Only one ring can be taken off or put on at a time. [In the toy, as usually sold, the first two rings form an exception to the rule. Both these can be taken off or put on together. To simplify the discussion I shall assume at first that only one ring is taken off or put on at a time.] I proceed to show that, if there are n rings, then in order to * It was described by Cardan in 1550 in his De Subtilitate, bk. xv, paragr. 2, ed. Sponius, vol. iii, p. 587; by Wallis in his Algebra, second edition, 1693, Opera, vol. ii, chap. 111, pp. 472–478; and allusion is made to it also in Ozanam's Récréations, 1723 edition, vol. iv, p. 439. 94 MISCELLANEOUS MATHEMATICAL RECREATIONS. [CH. IV disconnect them from the bar, it will be necessary to take a ring off or to put a ring on either 1 3 (2n+1 −1) times or 1 3 (2n+1 −2) times according as n is odd or even. Let the taking a ring off the bar or putting a ring on the bar be called a step. It is usual to number the rings from the free end A. Let us suppose that we commence with the first m rings off the bar and all the rest on the bar; and suppose that then it requires x − 1 steps to take off the next ring, that is, it requires x − 1 additional steps to arrange the rings so that the first m + 1 of them are off the bar and all the rest are on it. Before taking these steps we can take off the (m + 2)th ring and thus it will require x steps from our initial position to remove the (m + 1)th and (m + 2)th rings. Suppose that these x steps have been made and that thus the first m + 2 rings are off the bar and the rest on it, and let us find how many additional steps are now necessary to take off the (m + 3)th and (m + 4)th rings. To take these off we begin by taking off the (m + 4)th ring: this requires 1 step. Before we can take off the (m+ 3)th we must arrange the rings so that the (m + 2)th is on and the first m + 1 rings are off: to effect this, (i) we must get the (m + 1)th ring on and the first m rings off, which requires x − 1 steps, (ii) then we must put on the (m + 2)th ring, which requires 1 step, (iii) and lastly we must take the (m + 1)th ring off, which requires x − 1 steps: thus this series of movements requires in all {2(x − 1) + 1} steps. Next we can take the (m + 3)th ring off, which requires 1 step; this leaves us with the first m + 1 rings off, the (m + 2)th on, the (m + 3)th off and all the rest on. Finally to take off the (m + 2)th ring, (i) we get the (m + 1)th ring on and the first m rings off, which requires x − 1 steps, (ii) we take off the (m + 2)th ring, which requires 1 step, (iii) we take (m + 1)th ring off, which requires x − 1 steps: thus this series of movements requires {2(x − 1) + 1} steps. Therefore, if when the first m rings are off it

requires x steps to take off the (m + 1)th and (m + 2)th rings, then the number of additional steps required to take off the (m + 3)th and (m + 4)th rings is 1 + {2(x − 1) + 1} + 1 + {2(x − 1) + 1}, that is, is 4x. To find the whole number of steps necessary to take off an odd number of rings we proceed as follows. To take off the first ring requires 1 step; ∴ to take off the first 3 rings requires 4 additional steps; ∴ " " 5 " " 4 2 " " . CH. IV] CHINESE RINGS. 95 In this way we see that the number of steps required to take off the first 2n + 1 rings is 1 + 4 + 42 + · · · + 4n , which is equal to 1 3 (22n+2 − 1). To find the number of steps necessary to take off an even number of rings we proceed in a similar manner. To take off the first 2 rings requires 2 steps; ∴ to take off the first 4 rings requires 2 × 4 additional steps; ∴ " " 6 " " 2 × 4 2 " " . In this way we see that the number of steps required to take off the first 2n rings is 2 + (2 × 4) + (2 × 4 2) + · · · + (2 × 4 n−1), which is equal to 1 3 (22n+1 − 2). If we take off or put on the first two rings in one step instead of two separate steps, these results become respectively 2 2n and 2 2n−1 −1. I give the above analysis because it is the direct solution of a problem attacked by Cardan in 1550 and by Wallis in 1693—in both cases unsuccessfully—and which at one time attracted some attention. I proceed next to give another solution, more elegant though rather artificial. This solution, which is due to M. Gros* , depends on a convention by which any position of the rings is denoted by a certain number expressed in the binary scale of notation in such a way that a step is indicated by the addition or subtraction of unity. Let the rings be indicated by circles: if a ring is on the bar, it is represented by a circle drawn above the bar; if the ring is off the bar, it is represented by a circle below the bar. Thus figure i below represents a set of seven rings of which the first two are off the bar, the next three are on it, the sixth is off it, and the seventh is on it. Denote the rings which are on the bar by the digits 1 or 0 alternately, reckoning from left to right, and denote a ring which is off the bar by the digit assigned to that ring on the bar which is nearest to it on the left of it, or by a 0 if there is no ring to the left of it. Thus the three positions indicated below are denoted respectively by the numbers written below them. The position represented in figure ii is obtained from that in figure i by putting the first ring on to the bar, while the position represented in figure iii is obtained from that in figure i by taking the fourth ring off the bar. It follows that every position of the rings is denoted by a number expressed in the binary scale: moreover, since in going from left to right * Théorie du Baguenodier, by L. Gros, Lyons, 1872. I take the account of this from Lucas, vol. i, part 7. 96 MISCELLANEOUS MATHEMATICAL RECREATIONS. [CH. IV ¶ ¶ ¶ ¶ ¶ ¶ ¶ 1101000 Figure i. ¶ ¶ ¶ ¶ ¶ ¶ ¶ 1101001 Figure ii. ¶ ¶ ¶ ¶ ¶ ¶ ¶ 1100111 Figure iii. every ring on the bar gives a variation (that is, 1 to 0 or 0 to 1) and every ring off the bar gives a continuation, the effect of a step by which a ring is taken off or put on the bar is either to subtract unity from this number or to add unity to it. For example, the number denoting the position of the rings in figure ii is obtained from the number

denoting that in figure i by adding unity to it. Similarly the number denoting the position of the rings in figure iii is obtained from the number denoting that in figure i by subtracting unity from it. The position when all the seven rings are off the bar is denoted by the number 0000000: when all of them are on the bar by the number 1010101. Hence to change from one position to the other requires a number of steps equal to the difference between these two numbers in the binary scale. The first of these numbers is 0: the second is equal to 2 6 + 24 + 22 + 1, that is, to 85. Therefore 85 steps are required. In a similar way we may show that to put on a set of 2n + 1 rings requires (1 + 21 + 22 + . . . + 22n) steps, that is, 1 3 (22n+2 − 1) steps; and to put on a set of 2n rings requires (2 + 23 + . . . + 22n−1) steps, that is, 1 3 (2n+1 − 2) steps. I append a table indicating the steps necessary to take off the first four rings from a set of five rings. The diagrams in the middle column show the successive position of the rings after each step. The number following each diagram indicates that position, each number being obtained from the one above it by the addition of unity. The steps which are bracketed together can be made in one movement, and, if thus effected, the whole process is completed in 7 movements instead of 10 steps: this is in accordance with the formula given above. M. Gros asserted that it is possible to take from 64 to 80 steps a minute, which in my experience is a rather high estimate. If we accept the lower of these numbers, it would be possible to take off 10 rings in less than 8 minutes; to take off 25 rings would require more than 582 days, each of ten hours work; and to take off 60 rings would CH. IV] THE EIGHT QUEENS PROBLEM. 97 Initial position ” ” ” ” ” 10101 After 1st step ” ” ” ” ” 10110 } " 2nd " ” ” ” ” ” 10111 " 3rd " ” ” ” ” ” 11000 " 4th " ” ” ” ” ” 11001 } " 5th " ” ” ” ” ” 11010 " 6th " ” ” ” ” ” 11011 " 7th " ” ” ” ” ” 11100 " 8th " ” ” ” ” ” 11101 " 9th " ” ” ” ” ” 11110 } " 10th " ” ” ” ” ” 11111 necessitate no less than 768614, 336404, 564650 steps, and would require nearly 55000, 000000 years work—assuming of course that no mistakes were made. The Eight Queens Problem* . The determination of the number of ways in which eight queens can be placed on a chessboard—or more generally, in which n queens can be placed on a board of n 2 cells—so that no queen can take any other was proposed originally by Nauck in 1850. In 1874 Dr S. Günther† suggested a method of solution by means of determinants. For, if each symbol represents the corresponding cell of the board, the possible solutions for a board of n 2 cells are given by * On the history of this problem see W. Ahrens, Mathematische Unterhaltungen und Spiele, Leipzig, 1901, chap. ix—a work issued subsequent to the third edition of this book. † Grunert's Archiv der Mathematik und Physik, 1874, vol. lvi pp. 281–292. 98 MISCELLANEOUS MATHEMATICAL RECREATIONS. [CH. IV those terms, if any, of the determinant a1 b2 c3 d4 . . . . β2 a3 b4 c5 . . . . . γ3 β4 a5 b6 . . . . . δ4 γ5 β6 a7 . . . . . a2n−3 b2n−2 . . . . . β2n−2 a2n−1 in which no letter

and no suffix appears more than once. The reason is obvious. Every term in a determinant contains one and only one element out of every row and out of every column: hence any term will indicate a position on the board in which the queens cannot take one another by moves rook-wise. Again in the above determinant the letters and suffixes are so arranged that all the same letters and all the same suffixes lie along bishop's paths: hence, if we retain only those terms in each of which all the letters and all the suffixes are different, they will denote positions in which the queens cannot take one another by moves bishop-wise. It is clear that the signs of the terms are immaterial. In the case of an ordinary chess-board the determinant is of the 8th order, and therefore contains 8!, that is, 40320 terms, so that it would be out of the question to use this method for the usual chess-board of 64 cells or for a board of larger size unless some way of picking out the required terms could be discovered. A way of effecting this was suggested by Dr J.W.L. Glaisher* in 1874, and as far as I am aware the theory remains as he left it. He showed that if all the solutions of n queens on a board of n 2 cells were known, then all the solutions of a certain type for n + 1 queens on a board of (n+1)2 cells could be deduced, and that all the other solutions of n + 1 queens on a board of (n + 1)2 cells could be obtained without difficulty. The method will be sufficiently illustrated by one instance of its application. It is easily seen that there are no solutions when n = 2 and n = 3. If n = 4 there are two terms in the determinant which give solutions, namely, b2c5γ3β6 and c3β2b6γ5. To find the solutions when n = 5, * Philosophical Magazine, London, December, 1874, series 4, vol. xlviii, pp. 457– 467. CH. IV] THE EIGHT QUEENS PROBLEM. 99 Glaisher proceeded thus. In this case Günther's determinant is a1 b2 c3 d4 e5 β2 a3 b4 c5 d6 γ3 β4 a5 b6 c7 δ4 γ5 β6 a7 b8 ε5 δ6 γ7 β8 a9 To obtain those solutions (if any) which involve a9 it is sufficient to append a9 to such of the solutions for a board of 16 cells as do not involve a. As neither of those given above involves an a we thus get two solutions, namely, b2c5γ3β6a9 and c3β2b6γ5a9. The solutions which involve a1, e5 and ε5 can be written down by symmetry. The eight solutions thus obtained are all distinct; we may call them of the first type. The above are the only solutions which can involve elements in the corner squares of the determinant. Hence the remaining solutions are obtainable from the determinant 0 b2 c3 d4 0 β2 a3 b4 c5 d6 γ3 β4 a5 b6 c7 δ4 γ5 β6 a7 b8 0 δ6 γ7 β8 0 If, in this, we take the minor of b2 and in it replace by zero every term involving the letter b or the suffix 2 we shall get all solutions involving b2. But in this case the minor at once reduces to d6a5δ4β8. We thus get one solution, namely, b2d6a5δ4β8. The solutions which involve β2, δ4, δ6, β8, b8, d6, and d4 can be obtained by symmetry. Of these eight solutions it is easily seen that only two are distinct: these may be called solutions of the second type. Similarly the remaining solutions must be obtained from the determinant 0 0 c3 0 0 0 a3 b4 c5 0 γ3 β4 a5 b6 c7 0 γ5 β6 a7 0 0 0 γ7 0 0 If, in this, we take

the minor of c3, and in it replace by zero every term involving the letter c or the suffix 3, we shall get all the solutions 100 MISCELLANEOUS MATHEMATICAL RECREATIONS. [CH. IV which involve c3. But in this case the minor vanishes. Hence there is no solution involving c3, and therefore by symmetry no solutions which involve γ3, γ7, or c3. Had there been any solutions involving the third element in the first or last row or column of the determinant we should have described them as of the third type. Thus in all there are ten and only ten solutions, namely, eight of the first type, two of the second type, and none of the third type. Similarly, if n = 6, we obtain no solutions of the first type, four solutions of the second type, and no solutions of the third type; that is, four solutions in all. If n = 7, we obtain sixteen solutions of the first type, twenty-four solutions of the second type, no solutions of the third type, and no solutions of the fourth type; that is, forty solutions in all. If n = 8, we obtain sixteen solutions of the first type, fifty-six solutions of the second type, and twenty solutions of the third type, that is, ninety-two solutions in all. It will be noticed that all the solutions of one type are not always distinct. In general, from any solution seven others can be obtained at once. Of these eight solutions, four consist of the initial or fundamental solution and the three similar ones obtained by turning the board through one, two, or three right angles; the other four are the reflexions of these in a mirror: but in any particular case it may happen that the reflexions reproduce the originals, or that a rotation through one or two right angles makes no difference. Thus on boards of 4 2 , 5 2 , 6 2 , 7 2 , 8 2 , 9 2 , 102 cells there are respectively 1, 2, 1, 6, 12, 46, 92 fundamental solutions; while altogether there are respectively 2, 10, 4, 40, 92, 352, 724 solutions. The following collection of fundamental solutions may interest the reader. The positions on the board of the queens are indicated by digits: the first digit represents the number of the cell occupied by the queen in the first column reckoned from one end of the column, the second digit the number in the second column, and so on. Thus on a board of 4 2 cells the solution 3142 means that one queen is on the 3rd square of the first column, one on the 1st square of the second column, one on the 4th square of the third column, and one on the 2nd square of the fourth column. If a fundamental solution gives rise to only four solutions the number which indicates it is placed in curved brackets, ( ); if it gives rise to only two solutions the number which indicates it is placed in square brackets, [ ]; the other fundamental solutions give rise CH. IV] THE EIGHT QUEENS PROBLEM. 101 to eight solutions each. On a board of 4 2 cells there is 1 fundamental solution: namely, [3142]. On a board of 5 2 cells there are 2 fundamental solutions: namely, 14253, [25314]. On a board of 6 2 cells there is 1 fundamental solution: namely, (246135). On a board of 7 2 cells there are 6 fundamental solutions: namely, 1357246, 3572461, (5724613), 4613572, 3162574, (2574136). On a board of 8 2 cells there are 12 fundamental solutions: namely, 25713864, 57138642, 71386425, 82417536, 68241753, 36824175,

64713528, 36814752, 36815724, 72418536, 26831475, (64718253). The arrangement in this order is due to Mr Oram. It will be noticed that the 10th, 11th, and 12th solutions somewhat resemble the 4th, 6th, and 7th respectively. The 6th solution is the only one in which no three queens are in a straight line. On a board of 9 2 cells there are 46 fundamental solutions; one of them is 248396157. On a board of 102 cells there are 92 fundamental solutions; these were given by Dr A. Pein* ; one of them is 2468t13579, where t stands for ten. On a board of 112 cells there are 341 fundamental solutions; these have been given by Dr T.B. Sprague† : one of them is 15926t37e48. I may add that for a board of n 2 cells there is always a symmetrical solution of the form 246 . . . n135 . . .(n−1), when n = 6m or n = 6m + 4, Also Mr Oram has shown that for a board of n 2 cells, when n is a prime, cyclical arrangements of the n natural numbers, other than in their natural order, will give solutions; see, for instance, the solution quoted above. The puzzle in the form of a board of 36 squares is sold in the streets of London for a penny, a small wooden board being ruled in the manner shown in the diagram and having holes drilled in it at the points marked by dots. The object is to put six pins into the holes so that no two are connected by a straight line. * Aufstellung von n Königinnen auf einem Schachbrett von n 2 Feldern, Leipzig, 1889. † Proceedings of the Edinburgh Mathematical Society, vol. xvii, 1898–9, pp. 43–68. 102 MISCELLANEOUS MATHEMATICAL RECREATIONS. [CH. IV Other Problems with Queens. Captain Turton called my attention to two other problems of a somewhat analogous character, neither of which, as far as I know, has been published elsewhere, or solved otherwise than empirically. The first of these is to place eight queens on a chess-board so as to command the fewest possible squares. Thus, if queens are placed on cells 1 and 2 of the second column, on cell 2 of the sixth column, on cells 1, 3, and 7 of the seventh column, and on cells 2 and 7 of the eighth column, eleven cells on the board will not be in check; the same number can be obtained by other arrangements. Is it possible to place the eight queens so as to leave more than eleven cells out of check? I have never succeeded in doing so, nor in showing that it is impossible to do it. The other problem is to place m queens (m being less than 5) on a chess-board so as to command as many cells as possible. For instance, four queens can be placed in several ways on the board so as to command 58 cells besides those on which the queens stand, thus leaving only 2 cells which are not commanded: ex. gr. this is effected if the queens are placed on cell 5 of the third column, cell 1 of the fourth column, cell 6 of the seventh column, and cell 2 of the eighth column; or on cell 1 of the first column, cell 7 of the third column, cell 3 of the fifth column, and cell 5 of the seventh column. A similar problem is to determine the minimum number and the position of queens which can be placed on a board of n 2 cells so as to occupy or command every cell. It would seem that, even with the additional restriction that no queen shall be able to take any other queen, there are no

less than ninety-one typical solutions in which five queens can be placed on a chess-board CH. IV] THE FIFTEEN SCHOOL-GIRLS PROBLEM. 103 so as to command every cell* . Extension to other Chess Pieces. Analogous problems may be proposed with other chess-pieces. For instance, questions as to the maximum number of knights which can be placed on a board of n 2 cells so that no knight can take any other, and the minimum number of knights which can be placed on it so as to occupy or command every cell have been propounded† . Similar problems have also been proposed for k kings placed on a chess-board of n 2 cells‡ . It has been asserted that, if k = 2, the number of ways in which two kings can be placed on a board so that they may not occupy adjacent squares is 1 2 (n − 1)(n − 2)(n 2 + 3n − 2). Similarly, if k = 3, the number of ways in which three kings can be placed on a board so that no two of them occupy adjacent squares is said to be 1 6 (n − 1)(n − 2)(n 4 + 3n 3 − 20n 2 − 30n + 132). The Fifteen School-Girls Problem. This problem— which was first enunciated by Mr T.P. Kirkman, and is sometimes known as Kirkman's problem§—consists in arranging fifteen things in different sets of triplets. It is usually presented in the form that a school-mistress was in the habit of taking her girls for a daily walk. * L'Intermédiaire des mathématiciens, Paris, 1901, vol. viii, p. 88. † Ibid., March, 1896, vol. iii, p. 58; 1897, vol. iv, p. 15, 254; and 1898, vol. v, p. 87. ‡ Ibid., June, 1901, p. 140. § It was published first in the Lady's and Gentleman's Diary for 1850, p. 48, and has been the subject of numerous memoirs. Among these I may single out the papers by A. Cayley in the Philosophical Magazine, July, 1850, series 3, vol. xxxvii, pp. 50–53; by T.P. Kirkman in the Cambridge and Dublin Mathematical Journal, 1850, vol. v, p. 260; by R.R. Anstice, Ibid., 1852, vol. vii, pp. 279–292; by B. Pierce, Gould's Journal, Cambridge, U.S., 1860, vol. vi, pp. 169–174; by T.P. Kirkman, Philosophical Magazine, March, 1862, series 4, vol. xxiii, pp. 198–204; by W.S.B. Woolhouse in the Lady's Diary for 1862, pp. 84–88, and for 1863, pp. 79–90, and in the Educational Times Reprints, 1867, vol. viii, pp. 76–83; by J. Power in the Quarterly Journal of Mathematics, 1867, vol. viii, pp. 236–251; by A.H. Frost, Ibid., 1871, vol. xi, pp. 26–37; by E. Carpmael in the Proceedings of the London Mathematical Society, 1881, vol. xii, pp. 148–156; by Lucas in his Récréations, vol. ii, part vi; by A.C. Dixon in the Messenger of Mathematics, Cambridge, October, 1893, vol. xxiii, pp. 88– 89; and by W. Burnside, Ibid., 1894, vol. xxiii, pp. 137–143. It has also, since the issue of my third edition, been discussed by W. Ahrens in his Mathematische Unterhaltungen und Spiele, Leipzig, 1901, chapter xiv. 104 MISCELLANEOUS MATHEMATICAL RECREATIONS. [CH. IV The girls were fifteen in number, and were arranged in five rows of three each so that each girl might have two companions. The problem is to dispose them so that for seven consecutive days no girl will walk with any of her school-fellows more than once. More generally we may require to arrange 3m girls in triplets to walk out for 1 2 (3m − 1) days, so that no girl will walk with any of her school-fellows more than once. The theory of the

formation of all such possible triplets in the case of fifteen girls is not difficult, but the extension to 3m girls is, as yet, unsolved. I proceed to describe three methods of solution: these methods are analytical, but I may add that the problem can be also attacked by geometrical methods. Frost's Method. The first of these solutions is due to Mr Frost. A full exposition of it would occupy a good deal of space, but I hope that the following sketch will make the process intelligible. Denote one of the girls by k. Her companions on each day are different: suppose that on Sunday they are a1 and a2, on Monday b1 and b2, and so on, and finally on Saturday g1 and g2. Hence for each day we have one triplet, and we have to find four others, but in each of the latter no two like letters can occur together, that is, the three letters in any of them must be all different. Let a stand for a1, or a2, b for b1 or b2, and so on. The suffixes 1 and 2 are called complementary. Then, since the three letters in each of the triplets we are trying to find must be different, we must make some arrangement such as putting a with bc, de, and fg; and, if so, b may be associated with df and eg; and c with dg and ef. Thus there are seven possible triads, such as abc, ade, afg, bdf, beg, cdg, and cef. Moreover each of these may stand for any one of four triplets: for instance, the triad bdf may stand for any of the triplets b1d1f1, b1d2f2, b2d1f2, b2d2f1. The four triads which do not involve a must be placed in the Sunday column, the four which do not involve b in the Monday column, and so on. Thus each triad will occur four times. It only remains to insert the proper suffixes. This is done as follows. Take one triad, such as bdf, and insert a different set of suffixes each time that it occurs; for instance, the four sets given above. Next, the other like letters (b, d, or f as the case may be) in these four columns must have the complementary suffixes attached. After this is done, the next triplet in the Sunday column will be b2eg. The triad beg occurs in four columns and includes four possi- CH. IV] THE FIFTEEN SCHOOL-GIRLS PROBLEM. 105 ble triplets, such as b2e1g1, b2e2g2, b1e1g2, b1e2g1. Insert these, and then give the complementary suffixes to the other like letters in these four columns. In this way the arrangement is constructed gradually, by taking one triad at a time, inserting the proper suffixes to the four triplets included in it, and then the complementary suffixes in the other like letter in the same columns. One final arrangement, thus obtained, is as follows: Sunday Monday Tuesday Wednesday Thursday Friday Saturday ka1a2 kb1b2 kc1c2 kd1d2 ke1e2 kf1f2 kg1g2 b1d1f1 a1d2e2 a1d1e1 a2b2c2 a2b1c1 a1b2c1 a1b1c2 b2e1g1 a2f2g2 a2f1g1 a1f2g1 a1f1g2 a2d2e1 a2d1e2 c1d2g2 c1d1g1 b1d2f2 b1e1g2 b2d1f2 b1e2g1 b2d2f1 c2e2f2 c2e1f1 b2e2g2 c1e2f1 c2d2g1 c2d1g2 c1e1f2 We might obtain other solutions by selecting other seven triads or by choosing other arrangements of the suffixes in each triad (or by merely interchanging letters and suffixes in the above order). By these means Mr Power showed that there are no less than 15567, 552000 different solutions; but, since the total number of ways in which the school can walk out for a week in triplets is (455)7 , the probability

that any chance way satisfies Kirkman's condition is very small. Frost's method is applicable to the case of 2 2n −1 girls walking out for 2 2n−1 − 1 days in triplets. The detailed solution for 63 girls walking out for 31 days, which corresponds to n = 3, have been given. Anstice's Method. Another method of attacking the problem is due to Mr Anstice; it is illustrated by the following elegant solution, by which from the order on Sunday we can obtain the order on the following six days by a cyclical permutation. Let the girls be denoted respectively by the letters k, a1, a2, a3, a4, a5, a6, a7, b1, b2, b3, b4, b5, b6, b7; and suppose the order on Sunday to be ka1b1, a2a3a5, a4b3b6, a6b2b7, a7b4b5 . Then, if the suffixes are permuted cyclically, we obtain six other arrangements which satisfy the conditions of the problem: the reason being that in the above arrangement the difference of the suffixes of every pair of like letters—such as either the "a"s or the "b"s—in a triplet 106 MISCELLANEOUS MATHEMATICAL RECREATIONS. [CH. IV is different for each triplet, as also is the difference of the suffixes of every pair of unlike letters which are in a triplet. Two other arrangements for Sunday, from which those for the remaining days are obtainable by cyclical permutations can be formed. These are ka1b1, a2a3a5, a4b5b7, a6b3b4, a7b2b6; and ka1b1, a2a3a5, a4b2b6, a6b5b7, a7b3b4. Anstice's method is applicable to the case of 2p + 1 girls walking out for p days in triplets so that no pair may walk together more than once, provided p is a prime of the form 12m + 7. In such a case he showed how to construct a fundamental arrangement for one day from which the arrangements for the remaining p − 1 days can be obtained by cyclical permutations of suffixes. The number of such fundamental arrangements is 3(2m + 1)(3m + 1). The problem of 15 girls corresponds to m = 0, and the three fundamental Anstician arrangements are given above. If m = 1 we have the problem of 39 girls. One Anstician arrangement in this case is as follows: ka1b1, a2a8a12, a5a7a10, a6a17a18, a3b10b15, a4b3b5, a9b18b19, a11b8b14, a13b9b17, a14b12b16, a15b4b7, a16b2b11, a19b6b13. If m = 2 we have the problem of 63 girls, of which Frost has given one solution; and so on. Gill's Method. Another method of attacking the problem has been suggested to me by Mr T.H. Gill. Representing the girls by a1, a2, a3, . . . , a3m he (i) forms one triplet of the type a1am+1a2m+1, from which, by cyclical permutation of the suffixes 1, 2, . . . , 3m he obtains m triplets which constitute an arrangement for one day, and (ii) forms 1 2 (m − 1) other triplets such that the three differences of the suffixes are different, from which, by cyclical permutations of the suffixes, the arrangements for the remaining 3 2 (m − 1) other days can be obtained. Thus in the case of 15 girls, the triplet a1a6a11 gives, by cyclical permutations of the suffixes, an arrangement for the first day and two triplets such as a1a2a5, a1a3a9 enable us to form 30 triplets from which an arrangement for the other six days can be found. Here is a solution thus determined. First Day: 1. 6.11; 2. 7.12; 3. 8.13; 4. 9.14; 5.10.15 . Second Day: 1. 2. 5; 3. 4. 7; 8. 9.12; 10.11.14; 13.15. 6 . Third Day: 2. 3. 6; 4. 5. 8;

9.10.13; 11.12.15; 14. 1. 7 . Fourth Day: 5. 6. 9; 7. 8.11; 12.13. 1; 14.15. 3; 2. 4.10 . Fifth Day: 7. 9.15; 8.10. 1; 3. 5.11; 4. 6.12; 13.14. 2 . Sixth Day: 9.11. 2; 10.12. 3; 5. 7.13; 6. 8.14; 15. 1. 4 . Seventh Day: 11.13. 4; 12.14. 5; 15. 2. 8; 1. 3. 9; 6. 7.10 . CH. IV] THE FIFTEEN SCHOOL-GIRLS PROBLEM. 107 But, although this method gives triplets with which the problem can be solved, the final arrangement is empirical. A solution of the problem of 21 girls for 10 days can be got by the same method: a1a8a15 giving 7 triplets which constitute an arrangement for one day; and a1a2a6, a1a3a11, a1a4a10 giving 63 triplets from which an arrangement for the other nine days can be formed. Here is the solution thus determined. First Day: 1. 8.15; 2. 9.16; 3.10.17; 4.11.18; 5.12.19; 6.13.20; 7.14.21 . Second Day: 1. 2. 6; 4. 5. 9; 7. 8.12; 10.11.15; 13.14.18; 16.17.21; 19.20. 3 . Third Day: 7.10.16; 8.11.17; 12.15.21; 18.19. 2; 20. 1. 9; 3. 5.13; 4. 6.14 . Fourth Day: 13.16. 1; 14.17. 2; 18.21. 6; 3. 4. 8; 5. 7.15; 9.11.19; 10.12.20 . Fifth Day: 4. 7.13; 5. 8.14; 9.12.18; 15.16.20; 17.19. 6; 21. 2.10; 1. 3.11 . Sixth Day; 1. 4.10; 2. 5.11; 6. 9.15; 12.13.17; 14.16. 3; 18.20. 7; 19.21. 8 . Seventh Day: 2. 3. 7; 5. 6.10; 8. 9.13; 11.12.16; 14.15.19; 17.18. 1; 20.21. 4 . Eighth Day: 10.13.19; 11.14.20; 15.18. 3; 21. 1. 5; 2. 4.12; 6. 8.16; 7. 9.17 . Ninth Day: 16.19. 4; 17.20. 5; 21. 3. 9; 6. 7.11; 8.10.18; 12.14. 1; 13.15. 2 . Tenth Day: 19. 1. 7; 20. 2. 8; 3. 6.12; 9.10.14; 11.13.21; 15.17. 4; 16.18. 5 . I should be interested if any of my readers could give me a similar solution of the analogous arrangement of 33 girls for 16 days formed from typical triplet suffixes like 1, 12, 23; 1, 2, 10; 1, 3, 16; 1, 4, 18; 1, 5, 11; 1, 6, 13; or from other sets of triplets formed in a similar way so that (except in the first triplet) the differences of the suffixes are all different. Walecki's Theorem. Lastly, Walecki—quoted by Lucas—has shown that, if a solution for the case of n girls walking out in triplets for 1 2 (n − 1) days is known, then a solution for 3n girls walking out for 1 2 (3n − 1) days can be deduced. For if an arrangement of the n girls, a1, a2, . . . , an for 1 2 (n−1) days is known; and also one of the n girls, b1, b2, . . . , bn; and also one of the n girls c1, c2, . . . , cn; then an arrangement of these 3n girls for 1 2 (n − 1) days is known. A set of n triplets for another day will be given by ambm+kcm+2k where m is put equal to 1, 2, . . . , n successively. Here k may have any of the n values, 0, 1, 2, . . . ,(n − 1); but, wherever a suffix is greater than n, it is to be divided by n and only the remainder retained. Hence altogether we have an arrangement for n + 1 2 (n − 1) days, i.e. for 1 2 (3n − 1) days. The arrangement of 3 girls for one day is obvious. Hence, by Walecki's theorem, we can deduce at once an arrangement of 3 m girls for 1 2 (3m − 1) days. And, generally, as I have given solutions of the problem in the case of 3n girls when n = 1, 3, 5, 7, 9, 13, 15, it follows 108 MISCELLANEOUS MATHEMATICAL RECREATIONS. [CH. IV that for the same values of n, we can solve the analogous arrangements of 3 m × n girls. To the original theorem J.J. Sylvester* added the corollary that the school of 15 girls could walk out in triplets on 13 × 7 days until every possible triplet had walked abreast once. The generalized problem of finding the

greatest number of ways in which x girls walking in rows of a abreast can be arranged so that every possible combination of b of them may walk abreast once and only once has been solved for various cases. Suppose that this greatest number of ways is y. It is obvious that, if all the x girls are to walk out each day in rows of a abreast, then x must be an exact multiple of a and the number of rows formed each day is x/a. If such an arrangement can be made for z days, then we have a solution of the problem to arrange x girls to walk out in rows of a abreast for z days so that they all go out each day and so that every possible combination of b girls may walk together once, and only once. In the corresponding generalization of Kirkman's problem no companionship of girls which has occurred once may occur again, but it does not follow necessarily that every possible companionship must occur once. An example where the solution is obvious is if x = 2n, a = 2, b = 2, in which case y = n(2n − 1), z = 2n − 1. If we take the case x = 15, a = 3, b = 2, we find y = 35; and it happens that these 35 rows can be divided into 7 sets, each of which contains all the symbols; hence z = 7. More generally, if x = 5 × 3 m, a = 3, b = 2, we find y = 3 2 (x − 1)/x, z = 1 2 (x − 1). It will be noticed that in the solutions of the original fifteen school-girls problem and of Walecki's extension of it given above every possible pair of girls walk together once; hence we might infer that in these cases we could determine z as well as y. The results of the last paragraph were given by Kirkman† in 1850. In the same memoir he also proved that, if p is a prime, and if x = p m, a = p, b = 2, then y = (p m − 1)/(p − 1); if x = (p 2 + p + 1)(p + 1) where p 2 + p + 1 has no divisor less than p + 1, a = p + 1, b = 2, then y = x(x − 1)/p(p + 1); if x = p 3 + p + 1, a = p + 1, b = 2, then y = x; * Philosophical Magazine, July, 1850, series 3, vol. xxxvii, p. 52; a solution by Sylvester is given in the Philosophical Magazine, May, 1861, series 4, vol. xxi, p. 371. † Cambridge and Dublin Mathematical Journal, 1850, vol. v, pp. 255–262. CH. IV] PROBLEMS CONNECTED WITH A PACK OF CARDS. 109 and Sylvester's result that if x = 15, a = 3, b = 3, y = 455, z = 91. Three years later Kirkman* solved the problem when x = 2n , a = 4, b = 3. Lastly, in 1893, Sylvester† published the solution when x = 9, a = 3, b = 3, in which case y = 84, z = 28; and stated that a similar method was applicable when x = 3m, a = 3, b = 3: thus 9 girls can be arranged to walk out 28 times (say 4 times a day for a week) so that in any day the same pair never are together more than once and so that at the end of the week each girl has been associated with every possible pair of her schoolfellows. In 1867 Mr S. Bills‡ showed that if x = 7, a = 3, b = 2, then y = 7: if x = 15, a = 3, b = 2, then y = 35: if x = 31, a = 3, b = 2, then y = 155: and the method by which these results are proved will give the value of y, if x = 2n − 1, a = 3, b = 2. Shortly afterwards Mr W. Lea§ showed that if x = 11, a = 5, b = 4, then y = 66; also that if x = 16, a = 4, b = 3, then y = 140; the latter result is a particular case of Kirkman's theorems. It will be noticed that these writers did not confine their discussion to cases where x is an exact multiple of a. Problems connected with a

Pack of Cards. I mentioned in chapter i that an ordinary pack of playing cards could be used to illustrate many tricks depending on simple properties of numbers. Most of these involve the relative position of the cards. The principle of solution generally consists in re-arranging the pack in a particular manner so as to bring the card into some definite position. Any such rearrangement is a species of shuffling. I shall treat in succession of problems connected with shuffling a pack, arrangements by rows and columns, the determination of a pair out of 1 2 n(n + 1) pairs, Gergonne's pile problem, and the game known as the mouse trap. Shuffling a Pack. Any system of shuffling a pack of cards, if carried out consistently, leads to an arrangement which can be calculated; but tricks that depend on it generally require considerable * Ibid., 1853, vol. viii, pp. 38–42. † Messenger of Mathematics, February, 1893, vol. xxii, pp. 159–160. ‡ Educational Times Reprints, London, 1867, vol. viii, pp. 32–33. § Ibid., 1868, vol. ix, pp. 35–36; and 1874, vol. xxii, pp. 74–76; see also the volume for 1869, vol. xi, p. 97. 110 MISCELLANEOUS MATHEMATICAL RECREATIONS. [CH. IV technical skill. Suppose for instance that a pack of n cards is shuffled, as is not unusual, by placing the second card on the first, the third below these, the fourth above them, and so on. The theory of this system of shuffling is due to Monge* . The following are some of the results and are not difficult to prove directly. If the pack contains 6p + 4 cards, the (2p + 2)th card will occupy the same position in the shuffled pack. For instance, if a complete pack of 52 cards is shuffled as described above, the 18th card will remain the 18th card. Again, if a pack of 10p+2 cards is shuffled in this way, the (2p+1)th and the (6p × 2)th cards will interchange places. For instance, if an écarté pack of 32 cards is shuffled as described above, the 7th and the 20th cards will change places. More generally, one shuffle of a pack of 2p cards will move the card which was in the x0th place to the x1th place, where x1 = 1 2 (2p+x0+1) if x0 is odd, and x1 = 1 2 (2p − x0 + 2) if x0 is even, from which the above results can be deduced. By repeated applications of the above formulae we can show that the effect of m such shuffles is to move the card which was initially in the x0th place to the xmth place where 2 m+1xm = (4p + 1)(2m−1 ± 2 m−2 ± · · · ± 2 ± 1) ± 2x0 + 2m ± 1, the sign ± representing an ambiguity of sign. Again, in any pack of n cards after a certain number of shufflings, not greater than n, the cards will return to their primitive order. This will always be the case as soon as the original top card occupies that position again. To determine the number of shuffles required for a pack of 2p cards, it is sufficient to put xm = x0 and find the smallest value of m which satisfies the resulting equation for all values of x0 from 1 to 2p. It follows that, if m is the least number which makes 4 m − 1 divisible by 4p + 1, then m shuffles will be required if either 2 m + 1 or 2 m − 1 is divisible by 4p+ 1, otherwise 2m shuffles will be required. The number * Monge's investigations are printed in the Mémoires de l'Académie des Sciences, Paris, 1773, pp. 390–412. Among those who have studied the subject afresh I may in particular

mention V. Bouniakowski, Bulletin physico-mathématique de St Pétersbourg, 1857, vol. xv, pp. 202–205, summarised in the Nouvelles annales de mathématiques, 1858, pp. 66–67; T. de St Laurent, Mémoires de l'Académie de Gard, 1865; L. Tanner, Educational Times Reprints, 1880, vol. xxxiii, pp. 73– 75; and M.J. Bourget, Liouville's Journal, 1882, pp. 413–434. The solutions given by Prof. Tanner are simple and concise. CH. IV] PROBLEMS CONNECTED WITH A PACK OF CARDS. 111 for a pack of 2p+1 cards is the same as that for a pack of 2p cards. With an écarté pack of 32 cards, six shuffles are sufficient; with a pack of 2 n cards, n + 1 shuffles are sufficient; with a full pack of 52 cards, twelve shuffles are sufficient; with a pack of 13 cards ten shuffles are sufficient; while with a pack of 50 cards fifty shuffles are required; and so on. Mr W.H.H. Hudson* has also shown that, whatever is the law of shuffling, yet if it is repeated again and again on a pack of n cards, the cards will ultimately fall into their initial positions after a number of shufflings not greater than the greatest possible l.c.m. of all numbers whose sum is n. For suppose that any particular position is occupied after the 1st, 2nd, . . . , pth shuffles by the cards A1, A2, . . . , Ap respectively, and that initially the position is occupied by the card A0. Suppose further that after the pth shuffle A0 returns to its initial position, therefore A0 = Ap. Then at the second shuffling A2 succeeds A1 by the same law by which A1 succeeded A0 at the first; hence it follows that previous to the second shuffling A2 must have been in the place occupied by A1 previous to the first. Thus the cards which after the successive shuffles take the place initially occupied by A1 are A2, A3, . . . , Ap, A1; that is, after the pth shuffle A1 has returned to the place initially occupied by it: and so for all the other cards A2, A3, . . . , Ap−1. Hence the cards A1, A2, . . . , Ap form a cycle of p cards, one or other of which is always in one or other of p positions in the pack, and which go through all their changes in p shufflings. Let the number n of the pack be divided into p, q, r, . . . such cycles, whose sum is n; then the l.c.m. of p, q, r, . . . is the utmost number of shufflings necessary before all the cards will be brought back to their original places. In the case of a pack of 52 cards, the greatest l.c.m. of numbers whose sum is 52 will be found by trial to be 180180. Arrangements by Rows and Columns. A not uncommon trick, which rests on a species of shuffling, depends on the obvious fact that if n 2 cards are arranged in the form of a square of n rows, each containing n cards, then any card will be defined if the row and the column in which it lies are mentioned. This information is generally elicited by first asking in which row the selected card lies, and noting the extreme left-hand card of that * Educational Times Reprints, London, 1865, vol. ii, p. 105. 112 MISCELLANEOUS MATHEMATICAL RECREATIONS. [CH. IV row. The cards in each column are then taken up, face upwards, one at a time beginning with the lowest card of each column and taking the columns in their order from right to left–each card taken up being placed on the top of those previously taken up. The cards are then dealt out again in rows, from left to right, beginning with the top

lefthand corner, and a question is put as to which row contains the card. The selected card will be that card in the row mentioned which is in the same vertical column as the card which was originally noted. The above is the form in which the trick is usually presented, but it is greatly improved by allowing the pack to be cut as often as is liked before the cards are re-dealt, and then giving one cut at the end so as to make the top card in the pack one of those originally in the top row. The explanation is obvious. For, if 16 cards are taken, the first 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 Figure i. 1 5 9 13 2 6 10 14 3 7 11 15 4 8 12 16 Figure ii. and second arrangements may be represented by figures i and ii. For example, if we are told that in figure i the card is in the third row, it must be either 9, 10, 11, or 12: hence, if we know in which row of figure ii it lies, it is determined. If we allow the pack to be cut between the deals, we must secure somehow that the top card is either 1, 2, 3, or 4, since that will leave the cards in each row of figure ii unaltered though the positions of the rows will be changed. CH. IV] PROBLEMS CONNECTED WITH A PACK OF CARDS. 113 Determination of a selected pair of cards out of 1 2 n(n + 1) given pairs* . Another common trick is to throw twenty cards on to a table in ten couples, and ask someone to select one couple. The cards are then taken up, and dealt out in a certain manner into four rows each containing five cards. If the rows which contain the given cards are indicated, the cards selected are known at once. This depends on the fact that the number of homogeneous products of two dimensions which can be formed out of four things is 10. Hence the homogeneous products of two dimensions formed out of four things can be used to define ten things. Suppose that ten pairs of cards are placed on a table and someone selects one couple. Take up the cards in their couples. Then the first 1 2 3 5 7 4 9 10 11 13 6 12 15 16 17 8 14 18 19 20 two cards form the first couple, the next two the second couple, and so on. Deal them out in four rows each containing five cards according to the scheme shown in the diagram. The first couple (1 and 2) are in the first row. Of the next couple (3 and 4), put one in the first row and one in the second. Of the next couple (5 and 6), put one in the first row and one in the third, and so on, as indicated in the diagram. After filling up the first row proceed similarly with the second row, and so on. Enquire in which rows the two selected cards appear. If only one line, the mth, is mentioned as containing the cards then the required pair of cards are the mth and (m + 1)th cards in that line. These * Bachet, problem xvii, avertissement, p. 146 et seq. 114 MISCELLANEOUS MATHEMATICAL RECREATIONS. [CH. IV occupy the clue squares of that line. Next, if two lines are mentioned, then proceed as follows. Let the two lines be the pth and the qth and suppose q > p. Then that one of the required cards which is in the qth line will be the (q−p)th card which is below the first of the clue squares in the pth line. The other of the required cards is in the pth line and is the (q − p)th card to the right of the second of the clue squares. Bachet's rule, in the form in which I have given it, is

applicable to a pack of n(n + 1) cards divided into couples, and dealt in n rows each containing n + 1 cards; for there are 1 2 n(n + 1) such couples, also there are 1 2 n(n + 1) homogeneous products of two dimensions which can be formed out of n things. Bachet gave the diagrams for the cases of 20, 30, and 42 cards: these the reader will have no difficulty in constructing for himself, and I have enunciated the rule for 20 cards in a form which covers all the cases. I have seen the same trick performed by means of a sentence and not by numbers. If we take the case of ten couples, then after collecting the pairs the cards must be dealt in four rows each containing five cards, in the order indicated by the sentence Matas dedit nomen Cocis. This sentence must be imagined as written on the table, each word forming one line, The first card is dealt on the M. The next card (which is the pair of the first) is placed on the second m in the sentence, that is, third in the third row. The third card is placed on the a. The fourth card (which is the pair of the third) is placed on the second a, that is, fourth in the first row. Each of the next two cards is placed on a t, and so on. Enquire in which rows the two selected cards appear. If two rows are mentioned, the two cards are on the letters common to the words that make these rows. If only one row is mentioned, the cards are on the two letters common to that row. The reason is obvious: let us denote each of the first pair by an a, and similarly each of any of the other pairs by an e, i, o, c, d, m, n, s, or t respectively. Now the sentence Matas dedit nomen Cocis contains four words each of five letters; ten letters are used, and each letter is repeated only twice. Hence, if two of the words are mentioned, they will have one letter in common, or, if one word is mentioned, it will have two like letters. To perform the same trick with any other number of cards we should require a different sentence. The number of homogeneous products of three dimensions which CH. IV] PROBLEMS CONNECTED WITH A PACK OF CARDS. 115 can be formed out of four things is 20, and of these the number consisting of products in which three things are alike and those in which three things are different is 8. This leads to a trick with 8 trios of things, which is similar to that last given–the cards being arranged in the order indicated by the sentence Lanata levete livini novoto. I believe that these arrangements by sentences are known, but I am not aware who invented them. Gergonne's Pile Problem. Before discussing Gergonne's theorem I will describe the familiar three pile problem, the theory of which is included in his results. The Three Pile Problem* . This trick is usually performed as follows. Take 27 cards and deal them into three piles, face upwards. By "dealing" is to be understood that the top card is placed as the bottom card of the first pile, the second card in the pack as the bottom card of the second pile, the third card as the bottom card of the third pile, the fourth card on the top of the first one, and so on: moreover I assume that throughout the problem the cards are held in the hand face upwards. The result can be modified to cover any other way of dealing. Request a spectator to note

a card, and remember in which pile it is. After finishing the deal, ask in which pile the card is. Take up the three piles, placing that pile between the other two. Deal again as before, and repeat the question as to which pile contains the given card. Take up the three packs again, placing the pile which now contains the selected card between the other two. Deal again as before, but in dealing note the middle card of each pile. Ask again for the third time in which pile the card lies, and you will know that the card was the one which you noted as being the middle card of that pile. The trick can be finished then in any way that you like. The usual method—but a very clumsy one—is to take up the three piles once more, placing the named pile between the other two as before, when the selected card will be the middle one in the pack, that is, if 27 cards are used it will be the fourteenth. The trick is often performed with 15 cards or with 21 cards, in either of which cases the same rule holds. * The trick is mentioned by Bachet, problem xviii, p. 143, but his analysis of it is insufficient. 116 MISCELLANEOUS MATHEMATICAL RECREATIONS. [CH. IV Gergonne's Generalization. The general theory for a pack of mm cards was given by M. Gergonne* . Suppose the pack is arranged in m piles, each containing mm−1 cards, and that, after the first deal, the pile indicated as containing the selected card is taken up ath; after the second deal, is taken up bth; and so on, and finally after the mth deal, the pile containing the card is taken up kth. Then when the cards are collected after the mth deal the selected card will be nth from the top where if m is even, $n = kmm-1 - jmm-2 + \cdots + bm - a + 1$, if m is odd, $n = kmm-1 - jmm-2 + \cdots - bm + a$. For example, if a pack of 256 cards (i.e. m = 4) was given, and anyone selected a card out of it, the card could be determined by making four successive deals into four piles of 64 cards each, and after each deal asking in which pile the selected card lay. The reason is that after the first deal you know it is one of sixty-four cards. In the next deal these sixty-four cards are distributed equally over the four piles, and therefore, if you know in which pile it is, you will know that it is one of sixteen cards. After the third deal you know it is one of four cards. After the fourth deal you know which card it is. Moreover, if the pack of 256 cards is used, it is immaterial in what order the pile containing the selected card is taken up after a deal. For, if after the first deal it is taken up ath, after the second bth, after the third cth, and after the fourth dth, the card will be the (64d − 16c + 4b − a + 1)th from the top of the pack, and thus will be known. We need not take up the cards after the fourth deal, for the same argument will show that it is the (64 − 16c + 4b − a + 1)th in the pile then indicated as containing it. Thus if a = 3, b = 4, c = 1, d = 2, it will be the 62nd card in the pile indicated after the fourth deal as containing it and will be the 126th card in the pack as then collected. In exactly the same way a pack of twenty-seven cards may be used, and three successive deals, each into three piles of nine cards, will suffice to determine the card. If after the deals the pile indicated as containing the given card is taken up ath, bth, and cth respectively, then the

card will be the (9c − 3b + a)th in the pack or will be the (9 − 3b + a)th card in the pile indicated after the third deal as containing it. * Gergonne's Annales de Mathématiques, Nismes, 1813–4, vol. iv, pp. 276–283. CH. IV] PROBLEMS CONNECTED WITH A PACK OF CARDS. 117 The method of proof will be illustrated sufficiently by considering the usual case of a pack of twenty-seven cards, for which m = 3, which are dealt into three piles each of nine cards. Suppose that, after the first deal, the pile containing the selected card is taken up ath: then (i) at the top of the pack there are a − 1 piles each containing nine cards; (ii) next there are 9 cards, of which one is the selected card; and (iii) lastly there are the remaining cards of the pack. The cards are dealt out now for the second time: in each pile the bottom 3(a − 1) cards will be taken from (i), the next 3 cards from (ii), and the remaining 9 − 3a cards from (iii). Suppose that the pile now indicated as containing the selected card is taken up bth: then (i) at the top of the pack are 9(b − 1) cards; (ii) next are 9 − 3a cards; (iii) next are 3 cards, of which one is the selected card; and (iv) lastly are the remaining cards of the pack. The cards are dealt out now for the third time: in each pile the bottom 3(b − 1) cards will be taken from (i), the next 3 − a cards will be taken from (ii), the next card will be one of the three cards in (iii), and the remaining 8 − 3b + a cards are from (iv). Hence, after this deal, as soon as the pile is indicated, it is known that the card is the (9 − 3b + a)th from the top of that pile. If the process is continued by taking up this pile as cth, then the selected card will come out in the place 9(c − 1) + (8 − 3b + a) + 1 from the top, that is, will come out as the (9c − 3b + a)th card. Since, after the third deal, the position of the card in the pile then indicated is known, it is easy to notice the card, in which case the trick can be finished in some way more effective than dealing again. If we put the pile indicated always in the middle of the pack we have a = 2, b = 2, c = 2, hence n = 9c − 3b + a = 14, which is the form in which the trick is usually presented, as was explained above on page 115. I have shown that if a, b, c are known, then n is determined. We may modify the rule so as to make the selected card come out in any assigned position, say the nth. In this case we have to find values of a, b, c which will satisfy the equation n = 9c − 3b + a, where a, b, c can have only the values 1, 2, or 3. Hence, if we divide n by 3 and the remainder is 1 or 2, this remainder will be a; but, if the remainder is 0, we must decrease the quotient by unity so that the remainder is 3, and this remainder will be a. In 118 MISCELLANEOUS MATHEMATICAL RECREATIONS. [CH. IV other words a is the smallest positive number (exclusive of zero) which must be subtracted from n to make the difference a multiple of 3. Next let p be this multiple, i.e. p is the next lowest integer to n/3: then 3p = 9c−3b, therefore p = 3c−b. Hence b is the smallest positive number (exclusive of zero) which must be added to p to make the sum a multiple of 3, and c is that multiple. A couple of illustrations will make this clear. Suppose we wish the card to come out 22nd from the top, therefore 22 = 9c − 3b + a. The smallest number which must be subtracted from 22 to leave a

multiple of 3 is 1, therefore a = 1. Hence 22 = 9c − 3b + 1, therefore 7 = 3c − b. The smallest number which must be added to 7 to make a multiple of 3 is 2, therefore b = 2. Hence 7 = 3c − 2, therefore c = 3. Thus a = 1, b = 2, c = 3. Again, suppose the card is to come out 21st. Hence 21 = 9c−3b+a. Therefore a is the smallest number which subtracted from 21 makes a multiple of 3, therefore a = 3. Hence 6 = 3c − b. Therefore b is the smallest number which added to 6 makes a multiple of 3, therefore b = 3. Hence 9 = 3c, therefore c = 3. Thus a = 3, b = 3, c = 3. If any difficulty is experienced in this work, we can proceed thus. Let a = x + 1, b = 3 − y, c = z + 1; then x, y, z may have only the values 0, 1, or 2. In this case Gergonne's equation takes the form 9z + 3y + x = n − 1. Hence, if n − 1 is expressed in the ternary scale of notation, x, y, z will be determined, and therefore a, b, c will be known. The rule in the case of a pack of mm cards is exactly similar. We want to make the card come out in a given place. Hence, in Gergonne's formula, we are given n and we have to find a, b, . . . , k. We can effect this by dividing n continually by m, with the convention that the remainder are to be alternately positive and negative and that their numerical values are to be not greater than m or less than unity. An analogous theorem with a pack of lm cards can be constructed. C.T. Hudson and L.E. Dickson* have discussed the general case where such a pack is dealt n times, each time into l piles of m cards; and they have shown how the piles must be taken up in order that after the nth deal the selected card may be rth from the top. The principle will be sufficiently illustrated by one example treated in a manner analogous to the cases already discussed. For instance, * Educational Times Reprints, 1868, vol. ix, pp. 89–91; and Bulletin of the American Mathematical Society, New York, April, 1895, vol. i, pp. 184–186. CH. IV] PROBLEMS CONNECTED WITH A PACK OF CARDS. 119 suppose that an écarté pack of 32 cards is dealt into 4 piles each of 8 cards, and that the pile which contains some selected card is picked up ath. Suppose that on dealing again into four piles, one pile is indicated as containing the selected card, the selected card cannot be one of the bottom 2(a − 1) cards, or of the top 8 − 2a cards, but must be one of the intermediate 2 cards, and the trick can be finished in any way, as for instance by the common conjuring ambiguity of asking someone to choose one of them, leaving it doubtful whether the one he takes is to be rejected or retained. The Mouse Trap. I will conclude this chapter with the bare mention of another game of cards, known as the mouse trap, the discussion of which involves some rather difficult algebraic analysis. It is played as follows. A set of cards, marked with the numbers 1, 2, 3, . . . , n, is dealt in any order, face upwards, in the form of a circle. The player begins at any card and counts round the circle always in the same direction. If the kth card has the number k on it—which event is called a hit—the player takes up the card and begins counting afresh. According to Cayley, the player wins if he thus takes up all the cards, and the cards win if at any time the player counts up to n without being able to take up

a card. For example, if a pack of only four cards is used and these cards come in the order, 3214, then the player would obtain the second card 2 as a hit, next he would obtain 1 as a hit, but if he went on for ever he would not obtain another hit. On the other hand, if the cards in the pack were initially in the order 1423, the player would obtain successively all four cards in the order 1, 2, 3, 4. The problem may be stated as the determination of what hits and how many hits can be made with a given number of cards; and what permutations will give a certain number of hits in a certain order. Cayley* showed that there are 9 arrangements of a pack of four cards in which no hit will be made, 7 arrangements in which only one hit will be made, 3 arrangements in which only two hits will be made, and 5 arrangements in which four hits will be made. Prof. Steen† has investigated the general theory for a pack of n cards. He has shown how to determine the number of arrangements in * Quarterly Journal of Mathematics, 1878, vol. xv, pp. 8–10. † Ibid., vol. xv, pp. 230–241. 120 MISCELLANEOUS MATHEMATICAL RECREATIONS. [CH. IV which x is the first hit [Arts. 3–5]; the number of arrangements in which 1 is the first hit and x is the second hit [Art. 6]; and the number of arrangements in which 2 is the first hit and x the second hit [Arts. 7–8]; but beyond this point the theory has not been carried. It is obvious that, if there are n − 1 hits, the nth hit will necessarily follow. Treize. The French game of treize is very similar. It is played with a full pack of fifty-two cards (knave, queen, and king counting as 11, 12, and 13 respectively). The dealer calls out 1, 2, 3, . . . , 13, as he deals the 1st, 2nd, 3rd, . . . , 13th cards respectively. At the beginning of a deal the dealer offers to lay or take certain odds that he will make a hit in the thirteen cards next dealt. One of the innumerable forms of patience is played in a similar way. CHAPTER V. MAGIC SQUARES. A magic square consists of a number of integers arranged in the form of a square, so that the sum of the numbers in every row, in every column, and in each diagonal is the same. If the integers are the consecutive numbers from 1 to n 2 the square is said to be of the nth order, and it is easily seen that in this case the sum of the numbers in any row, column, or diagonal is equal to 1 2 n(n 2 + 1): this number may be denoted by N. I confine my account to such magic squares, that is, to squares formed with consecutive integers, from 1 upwards. Thus the first 16 integers, arranged in either of the forms given in figures i and ii below, form a magic square of the fourth order, the sum 1 15 14 4 12 6 7 9 8 10 11 5 13 3 2 16 Figure i. 15 10 3 6 4 5 16 9 14 11 2 7 1 8 13 12 Figure ii. of the numbers in any row, column, or diagonal being 34. Similarly figures iii and v on page 124, figure viii on page 126, and figures xii and xiii on page 136, show magic squares of the fifth order; and figure xi on page 133 shows a magic square of the sixth order; and figures xiv and xv on pages 137, 138, show magic squares of the eighth order. 121 122 MAGIC SQUARES. [CH. V The formation of these squares is an old amusement, and in times when mystical philosophical ideas were associated with particular numbers it was natural that such

arrangements should be deemed to possess magical properties. Magic squares of an odd order were constructed in India before the Christian era according to a law of formation which is explained hereafter. Their introduction into Europe appears to have been due to Moschopulus, who lived at Constantinople in the early part of the fifteenth century, and enunciated two methods for making such squares. The majority of the medieval astrologers and physicians were much impressed by such arrangements. In particular the famous Cornelius Agrippa (1486–1535) constructed magic squares of the orders 3, 4, 5, 6, 7, 8, 9, which were associated respectively with the seven astrological "planets": namely, Saturn, Jupiter, Mars, the Sun, Venus, Mercury, and the Moon. He taught that a square of one cell, in which unity was inserted, represented the unity and eternity of God; while the fact that a square of the second order could not be constructed illustrated the imperfection of the four elements, air, earth, fire, and water; and later writers added that it was symbolic of original sin. A magic square engraved on a silver plate was sometimes prescribed as a charm against the plague, and one, namely, that represented in figure i on page 121, is drawn in the picture of Melancholy, painted about the year 1500 by Albert Dürer. Such charms are still worn in the East. The development of the theory has been due mainly to French mathematicians. Bachet gave a rule for the construction of any square of an odd order in a form substantially equivalent to one of the rules given by Moschopulus. The formation of magic squares, especially of even squares, was considered by Frénicle and Fermat. The theory was continued by Poignard, De la Hire, Sauveur, D'Ons-en-bray, and Des Ourmes. Ozanam included in his work an essay on magic squares which was amplified by Montucla. From this and from De la Hire's memoirs the larger part of the materials for this chapter are derived. Like most algebraical problems, the construction of magic squares attracted the attention of Euler, but he did not advance the general theory. In 1837 an elaborate work on the subject was compiled by B. Violle, which is useful as containing numerous illustrations. I give the references in a footnote* . * Bachet, Problèmes plaisans, Lyons, 1624, problem xxi, p. 161; Frénicle, Divers Ouvrages de Mathématique par Messieurs de l'Académie des Sciences, Paris, CH. V] MAGIC SQUARES OF AN ODD ORDER.. 123 I shall confine myself to establishing rules for the construction of squares subject to no conditions beyond those given in the definition. Rules sufficient for this purpose are contained in the works to which I have just referred and on which I have based this sketch; some extensions and developments will be found in the memoirs mentioned below* . I shall commence by giving rules for the construction of a square of an odd order, and then shall proceed to similar rules for one of an even order. It will be convenient to use the following terms. The spaces or small squares occupied by the numbers are called cells. The diagonal from the top left-hand cell to the bottom right-hand cell is called the leading diagonal or left diagonal. The diagonal from the top right-

hand cell to the bottom left-hand cell is called the right diagonal. Magic Squares of an odd order. I proceed to give methods for constructing odd magic squares, but for simplicity I shall apply them to the formation of squares of the fifth order, though exactly similar 1693, pp. 423–483; with an appendix (pp. 484–507), containing diagrams of all the possible magic squares of the fourth order, 880 in number: Fermat, Opera Mathematica, Toulouse, 1679, pp. 173–178; or Brassinne's Précis, Paris, 1853, pp. 146–149: Poignard, Traité des Quarrés Sublimes, Brussels, 1704: De la Hire, Mémoires de l'Académie des Sciences for 1705, Paris, 1706, part i, pp. 127–171; part ii, pp. 364–382: Sauveur, Construction des Quarrés Magiques, Paris, 1710: D'Ons-en-bray, Mémoires de l'Académie des Sciences for 1750, Paris, 1754, pp. 241–271: Des Ourmes, Mémoires de Mathématique et de Physique (French Academy), Paris, 1763, vol. iv, pp. 196–241: Ozanam and Montucla, Récréations, part i, chapter xii: Euler, Commentationes Arithmeticae Collectae, St Petersburg, 1849, vol. ii, pp. 593–602: Violle, Traité Complet des Carrés Magiques, 3 vols, Paris, 1837–8. A sketch of the history of the subject is given in chap. iv of S. Günther's Geschichte der mathematischen Wissenschaften, Leipzig, 1876. See also W. Ahrens, Mathematische Unterhaltungen und Spiele, Leipzig, 1901, chapter xii. * In England the subject has been studied by R. Moon, Cambridge Mathematical Journal, 1845, vol. iv, pp. 209–214; H. Holditch, Quarterly Journal of Mathematics, London, 1864, vol. vi, pp. 181–189; W.H. Thompson, Ibid., 1870, vol. x, pp. 186–202; J. Horner, Ibid., 1871, vol. xi, pp. 57–65, 123–132, 213– 224; S.M. Drach, Messenger of Mathematics, Cambridge, 1873, vol. ii, pp. 169– 174, 187; A.H. Frost, Quarterly Journal of Mathematics, London, 1878, vol. xv, pp. 34–49, 93–123, 366–368, in which the results of previous memoirs are included: there are also some pamphlets and articles on it of a more popular character. Of recent Continental works on the subject I have no complete bibliography, and probably it is better to omit all rather than give an imperfect list. 124 MAGIC SQUARES. [CH. V proofs will apply equally to any odd square. De la Loubère's Method* . If the reader will look at figure iii he will see one way in which such a square containing 25 cells can be constructed. The middle cell in the top row is occupied by 1. The successive numbers are placed in their natural order in a diagonal line 17 24 1 8 15 23 5 7 14 16 4 6 13 20 22 10 12 19 21 3 11 18 25 2 9 De la Loubère's Method. Figure iii. 15 + 2 20 + 4 0 + 1 5 + 3 10 + 5 20 + 3 0 + 5 5 + 2 10 + 4 15 + 1 0 + 4 5 + 1 10 + 3 15 + 5 20 + 2 5 + 5 10 + 2 15 + 4 20 + 1 0 + 3 10 + 1 15 + 3 20 + 5 0 + 2 5 + 4 De la Loubère's Method. Figure iv. 23 6 19 2 15 10 18 1 14 22 17 5 13 21 9 4 12 25 8 16 11 24 7 20 3 Bachet's Method. Figure v. which slopes upwards to the right, except that (i) when the top row is reached the next number is written in the bottom row as if it came immediately above the top row; (ii) when the right-hand column is reached, the next number is written in the left-hand column, as if it immediately succeeded the right-hand column; and (iii) when a cell which has been filled up already, or

when the top right-hand square is reached, the path of the series drops to the row vertically below it and then continues to mount again. Probably a glance at the diagram in figure iii will make this clear. The reason why such a square is magic can be explained best by expressing the numbers in the scale of notation whose radix is 5 (or n, if the magic square is of the order n), except that 5 is allowed to appear as a unit-digit and 0 is not allowed to appear as a unit-digit. The result is shown in figure iv. From that figure it will be seen that the method of construction ensures that every row and every column shall contain one and only one of each of the unit-digits 1, 2, 3, 4, 5, the sum of which is 15; and also one and only one of each of the radix-digits 0, 5, 10, 15, 20, the sum of which is 50. Hence, as far as rows and columns are concerned, the square is magic. Moreover if the square is odd, each of the diagonals will contain one and only one of each of the unit-digits 1, 2, 3, 4, 5. Also the leading diagonal will contain one and only one * De la Loubère, Du Royaume de Siam (Eng. Trans.), London, 1693, vol. ii, pp. 227–247. De la Loubère was the envoy of Louis XIV to Siam in 1687–8, and there learnt this method. CH. V] MAGIC SQUARES OF AN ODD ORDER.. 125 of the radix-digits 0, 5, 10, 15, 20, the sum of which is 50; and if, as is the case in the square drawn above, the number 10 is the radix-digit to be added to the unit-digits in the right diagonal, then the sum of the radix-digits in that diagonal is also 50. Hence the two diagonals also possess the magical property. And generally if a magic square of an odd order n is constructed by De la Loubère's method, every row and every column must contain one and only one of each of the unit-digits 1, 2, 3 . . . , n; and also one and only one of each of the radix-digits 0, n, 2n, . . . , n(n − 1). Hence, as far as rows and columns are concerned, the square is magic. Moreover each diagonal will either contain one and only one of the unit-digits or will contain n unit-digits each equal to 1 2 (n + 1). It will also either contain one and only one of the radix-digits or will contain n radix-digits each equal to 1 2 n(n−1). Hence the two diagonals will also possess the magical property. Thus the square will be magic. I may notice here that, if we place 1 in any cell and fill up the square by De la Loubère's rule, we shall obtain a square that is magic in rows and in columns, but it will not in general be magic in its diagonals. It is evident that other squares can be derived from De la Loubère's square by permuting the symbols properly. For instance, in figure iv, we may permute the symbols 1, 2, 3, 4, 5 in 5! ways, and we may permute the symbols 0, 5, 15, 20 in 4! ways. Any one of these 5! arrangements combined with any one of these 4! arrangements will give a magic square. Hence we can obtain 2880 magic squares of the fifth order of this kind, though only 720 of them are really distinct. Other squares can however be deduced, for it may be noted that from any magic square, whether even or odd, other magic squares of the same order can be formed by the mere interchange of the row and the column which intersect in a cell on a diagonal with the row and the column which intersect in the complementary cell of the same diagonal. Bachet's

Method* . Another method, very similar to that of De la Loubère, for constructing an odd magic square is as follows. We begin by placing 1 in the cell above the middle one (that is, in a square of the fifth order in the cell occupied by the number 7 in figure iii), and then we write the successive numbers in a diagonal line sloping upwards to the right, subject to the condition that when the cases (i) and (ii) mentioned under De la Loubère's method occur the rules there * Bachet, Problem xxi, p. 161. 126 MAGIC SQUARES. [CH. V given are followed, but when the case (iii) occurs the path of the series rises two rows, i.e. it is continued from one cell to the cell next but one vertically above it, if this cell is above the top row the path continues from the corresponding cell in one of the bottom two rows following the analogy of rule (i) in De la Loubère's method. Such a square is delineated in figure v on page 124. Bachet's method leads ultimately to this arrangement; except that the rules are altered so as to make the line slope downwards. This method also gives 720 magic squares of the fifth order. De la Hire's Method* . I shall now give another rule for the formation of odd magic squares. To form an odd magic square of the order n by this method, we begin by constructing two subsidiary squares, one of the unit-digits, 1, 2, . . . , n, and the other of multiples of the radix, namely, 0, n, 2n, . . . ,(n − 1)n. We then form the magic square by adding together the numbers in the corresponding cells in the two subsidiary squares. De la Hire gave several ways of constructing such subsidiary squares. I select the following method (props. x and xiv of his memoir) as being the simplest, but I shall apply it to form a square of only the fifth order. It leads to the same results as the second of the two rules given by Moschopulus. The first of the subsidiary squares (figure vi, below), is constructed thus. First, 3 is put in the top left-hand corner, and then the numbers 1, 2, 4, 5 are written in the other cells of the top line (in any order). Next, the number in each cell of the top line is repeated in all the cells 3 4 1 5 2 2 3 4 1 5 5 2 3 4 1 1 5 2 3 4 4 1 5 2 3 First Subsidiary Square Figure vi. 15 0 20 5 10 0 20 5 10 15 20 5 10 15 0 5 10 15 0 20 10 15 0 20 5 Second Subsidiary Square Figure vii. 18 4 21 10 12 2 23 9 11 20 25 7 13 19 1 6 15 17 3 24 14 16 5 22 8 Resulting Magic Square Figure viii. which lie in a diagonal line sloping downwards to the right (see figure vi) according to the rule (ii) in De la Loubère's method. The cells filled by * Mémoires de l'Académie des Sciences for 1705, part i, pp. 127–171. CH. V] MAGIC SQUARES OF AN ODD ORDER.. 127 the same number form a broken diagonal. It follows that every row and every column contains one and only one 1, one and only one 2, and so on. Hence the sum of the numbers in every row and in every column is equal to 15; also, since we placed 3, which is the average of these numbers, in the top left-hand corner, the sum of the numbers in the left diagonal is 15; and, since the right diagonal contains one and only one of each of the numbers 1, 2, 3, 4, and 5, the sum of the numbers in that diagonal also is 15. The second of the subsidiary squares (figure vii) is constructed in a similar way with the numbers 0,

5, 10, 15, and 20, except that the mean number 10 is placed in the top right-hand corner; and the broken diagonals formed of the same numbers all slope downwards to the left. It follows that every row and every column in figure vii contains one and only one 0, one and only one 5, and so on; hence the sum of the numbers in every row and every column is equal to 50. Also the sum of the numbers in each diagonal is equal to 50. If now we add together the numbers in the corresponding cells of these two squares, we shall obtain 25 numbers such that the sum of the numbers in every row, every column, and each diagonal is equal to 15 + 50, that is, to 65. This is represented in figure viii. Moreover, no two cells in that figure contain the same number. For instance, the numbers 21 to 25 can occur only in those five cells which in figure vii are occupied by the number 20, but the corresponding cells in figure vi contain respectively the numbers 1, 2, 3, 4, and 5; and thus in figure viii each of the numbers from 21 to 25 occurs once and only once. De la Hire preferred to have the cells in the subsidiary squares which are filled by the same number connected by a knight's move and not by a bishop's move; and usually his rule is enunciated in that form. By permuting the numbers 1, 2, 4, 5 in figure vi we get 4! other arrangements, each of which combined with that in figure vii would give a magic square. Similarly by permuting the numbers 0, 5, 15, 20 in figure vii we obtain 4! other squares, each of which might be combined with any of the 4! arrangements deduced from figure vi. Hence altogether we can obtain in this way 576 magic squares of the fifth order. There is yet another method of constructing odd squares which is due to Poignard, and was improved by De la Hire in the memoir already cited. I shall not discuss it, because, though for certain assigned values of n it is simpler than the methods which I have given, it depends on 128 MAGIC SQUARES. [CH. V the form of n, and particularly on the number of prime factors of n. In the case of a square of the fifth order, this gives an even larger number of magic squares than the methods of De la Loubère, Bachet, and De la Hire. I may also add that it has been shown that magic squares whose order is a prime number can be constructed by a rule similar to De la Loubère's, except that we begin by placing 1 in the bottom left-hand cell, and the subsequent consecutive numbers fill cells forming a knight's path on the square and not a bishop's path. A square of the fifth order of this kind is given in figure xiii on page 136. There are 2880 magic squares of the fifth order of this kind. De la Hire showed that, apart from mere inversions, there were 57600 magic squares of the fifth order which could be formed by the methods he enumerated. Taking account of other methods, it would seem that the total number of magic squares of the fifth order is very large, perhaps exceeding 500000. Magic squares of an even order. The above methods are inapplicable to squares of an even order. I proceed to give two methods for constructing any even magic square of an order higher than two. It will be convenient to use the following terms. Two rows which are equidistant, the one from the top, the other

from the bottom, are said to be complementary. Two columns which are equidistant, the one from the left-hand side, the other from the right-hand side, are said to be complementary. Two cells in the same row, but in complementary columns, are said to be horizontally related. Two cells in the same column, but in complementary rows, are said to be vertically related. Two cells in complementary rows and columns are said to be skewly related; thus, if the cell b is horizontally related to the cell a, and the cell d is vertically related to the cell a, then the cells b and d are skewly related; in such a case if the cell c is vertically related to the cell b, it will be horizontally related to the cell d, and the cells a and c are skewly related: the cells a, b, c, d constitute an associated group, and if the square is divided into four equal quarters, one cell of an associated group is in each quarter. A horizontal interchange consists in the interchange of the numbers in two horizontally related cells. A vertical interchange consists in the interchange of the numbers in two vertically related cells. A skew interchange consists in the interchange of the numbers in two skewly related cells. A cross interchange consists in the change of the numbers CH. V] MAGIC SQUARES OF AN EVEN ORDER.. 129 in any cell and in its horizontally related cell with the numbers in the cells skewly related to them; hence, it is equivalent to two vertical interchanges and two horizontal interchanges. First Method* . This method is the simplest with which I am acquainted, and I believe, at any rate as far as concerns singly-even squares, was published for the first time in 1893. Begin by filling the cells of the square with the numbers 1, 2, . . . , n2 in their natural order commencing (say) with the top left-hand corner, writing the numbers in each row from left to right, and taking the rows in succession from the top. I will commence by proving that a certain number of horizontal and vertical interchanges in such a square must make it magic, and will then give a rule by which the cells whose numbers are to be interchanged can be at once picked out. First, we may notice that the sum of the numbers in each diagonal is equal to N, where N = 1 2 n(n 2 + 1); hence the diagonals are already magic, and will remain so if the numbers therein are not altered. Next, consider the rows. The sum of the numbers in the xth row from the top is N − 1 2 n 2 (n − 2x + 1). The sum of the numbers in the complementary row, that is, the xth row from the bottom, is N + 1 2 n 2 (n − 2x + 1). Also the number in any cell in the xth row is less than the number in the cell vertically related to it by n(n − 2x + 1). Hence, if in these two rows we make 1 2 n interchanges of the numbers which are situated in vertically related cells, then we increase the sum of the numbers in the xth row by 1 2 n × n(n − 2x + 1), and therefore make that row magic; while we decrease the sum of the numbers in the complementary row by the same number, and therefore make that row magic. Hence, if in every pair of complementary rows we make 1 2 n interchanges of the numbers situated in vertically related cells, the square will be made magic in rows. But, in order that the diagonals may remain magic, either we must leave both the

diagonal numbers in any row unaltered, or we must change both of them with those in the cells vertically related to them. The square is now magic in diagonals and in rows, and it remains to make it magic in columns. Taking the original arrangement of the numbers (in their natural order) we might have made the square magic in columns in a similar way to that in which we made it magic in rows. * See an article in the Messenger of Mathematics, Cambridge, September, 1893, vol. xxiii, pp. 65–69. 130 MAGIC SQUARES. [CH. V The sum of the numbers originally in the yth column from the left-hand side is N − 1 2 n(n − 2y + 1). The sum of the numbers originally in the complementary column, that is, the yth column from the right-hand side, is N + 1 2 n(n − 2y + 1). Also the number originally in any cell in the yth column was less than the number in the cell horizontally related to it by n−2y + 1. Hence, if in these two columns we had made 1 2 n interchanges of the numbers situated in horizontally related cells, we should have made the sum of the numbers in each column equal to N. If we had done this in succession for every pair of complementary columns, we should have made the square magic in columns. But, as before, in order that the diagonals might remain magic, either we must have left both the diagonal numbers in any column unaltered, or we must have changed both of them with those in the cells horizontally related to them. It remains to show that the vertical and horizontal interchanges, which have been considered in the last two paragraphs, can be made independently, that is, that we can make these interchanges of the numbers in complementary columns in such a manner as will not affect the numbers already interchanged in complementary rows. This will require that in every column there shall be exactly 1 2 n interchanges of the numbers in vertically related cells, and that in every row there shall be exactly 1 2 n interchanges of the numbers in horizontally related cells. I proceed to show how we can always ensure this, if n is greater than 2. I continue to suppose that the cells are initially filled with the numbers 1, 2, . . . , n2 in their natural order, and that we work from that arrangement. A doubly-even square is one where n is of the form 4m. If the square is divided into four equal quarters, the first quarter will contain 2m columns and 2m rows. In each of these columns take m cells so arranged that there are also m cells in each row, and change the numbers in these 2m2 cells and the 6m2 cells associated with them by a cross interchange. The result is equivalent to 2m interchanges in every row and in every column, and therefore renders the square magic. One way of selecting the 2m2 cells in the first quarter is to divide the whole square into sixteen subsidiary squares each containing m2 cells, which we may represent by the diagram below, and then we may take either the cells in the a squares or those in the b squares; thus, if every number in the eight a squares is interchanged with the number CH. V] MAGIC SQUARES OF AN EVEN ORDER.. 131 a b b a b a a b b a a b a b b a skewly related to it the resulting square is magic. A magic square of the eighth order, constructed in this way, is shown in figure

xv on page 138. Another way of selecting the 2m2 cells in the first quarter would be to take the first m cells in the first column, the cells 2 to m + 1 in the second column, and so on, the cells m + 1 to 2m in the (m + 1)th column, the cells m+2 to 2m and the first cell in the (m+2)th column, and so on, and finally the 2mth cell and the cells 1 to m − 1 in the 2mth column. A singly-even square is one where n is of the form 2(2m+1). If the square is divided into four equal quarters, the first quarter will contain 2m+1 columns and 2m+1 rows. In each of these columns take m cells so arranged that there are also m cells in each row: as, for instance, by taking the first m cells in the first column, the cells 2 to m + 1 in the second column, and so on, the cells m + 2 to 2m + 1 in the (m + 2)th column, the cells m + 3 to 2m + 1 and the first cell in the (m + 3)th column, and so on, and finally the (2m + 1)th cell and the cells 1 to m − 1 in the (2m + 1)th column. Next change the numbers in these m(2m+1) cells and the 3m(2m+1) cells associated with them by cross interchanges. The result is equivalent to 2m interchanges in every row and in every column. In order to make the square magic we must have 1 2 n, that is, 2m+1 such interchanges in every row and in every column, that is, we must have one more interchange in every row and in every column. This presents no difficulty, for instance, in the arrangement indicated above the numbers in the (2m + 1)th cell of the first column, in the first cell of the second column, in the second cell of the third column, and so on, to the 2mth cell in the (2m + 1)th column may be interchanged with the numbers in their vertically related cells; this will make all the rows magic. Next, the numbers in the 2mth cell of the first column, in the (2m + 1)th cell of the second column, in the first cell of the third column, in the second cell of the fourth column, and so on, to the (2m−1)th cell of the (2m+ 1)th column may be interchanged with those in the cells horizontally related to them; and this will make the 132 MAGIC SQUARES. [CH. V columns magic without affecting the magical properties of the rows. It will be observed that we have implicitly assumed that m is not zero, that is, that n is greater than 2; also it would seem that, if m = 1 and therefore n = 6, then the numbers in the diagonal cells must be included in those to which the cross interchange is applied, but, if n > 6, this is not necessary, though it may be convenient. The construction of odd magic squares and of doubly-even magic squares is very easy. But though the rule given above for singly-even squares is not difficult, it is tedious of application. It is unfortunate that no more obvious rule—such, for instance, as one for bordering a doubly-even square—can be suggested for writing down instantly and without thought singly-even magic squares. De la Hire's Method* . I now proceed to give another way due to De la Hire, of constructing any even magic square of an order higher than two. In the same manner as in his rule for making odd magic squares, we begin by constructing two subsidiary squares, one of the unit-digits, 1, 2, 3, . . . , n, and the other of the radix-digits 0, n, 2n, . . . ,(n − 1)n. We then form the magic square by adding together the numbers in the corresponding cells in the two

subsidiary squares. Following the analogy of the notation used above, two numbers which are equidistant from the ends of the series 1, 2, 3, . . . , n are said to be complementary. Similarly numbers which are equidistant from the ends of the series 0, n, 2n, . . . ,(n − 1)n are said to be complementary. For simplicity I shall apply this method to construct a magic square of only the sixth order, though an exactly similar method will apply to any even square of an order higher than the second. The first of the subsidiary squares (figure ix) is constructed as follows. First, the cells in the leading diagonal are filled with the numbers 1, 2, 3, 4, 5, 6 placed in any order whatever that puts complementary numbers in complementary positions (ex. gr. in the order 2, 6, 3, 4, 1, 5, or in their natural order 1, 2, 3, 4, 5, 6). Second, the cells vertically related to these are filled respectively with the same numbers. Third, each of the remaining cells in the first vertical column is filled * The rule is due to De la Hire (part 2 of his memoir) and is given by Montucla in his edition of Ozanam's work: I have used the modified enunciation of it inserted in Labosne's edition of Bachet's Problèmes, as it saves the introduction of a third subsidiary square. I do not know to whom the modification is due. CH. V] MAGIC SQUARES OF AN EVEN ORDER.. 133 1 5 4 3 2 6 6 2 4 3 5 1 6 5 3 4 2 1 1 5 3 4 2 6 6 2 3 4 5 1 1 2 4 3 5 6 First Subsidiary Square Figure ix. 0 30 30 0 30 0 24 6 24 24 6 6 18 18 12 12 12 18 12 12 18 18 18 12 6 24 6 6 24 24 30 0 0 30 0 30 Second Subsidiary Square Figure x. 1 35 34 3 32 6 30 8 28 27 11 7 24 23 15 16 14 19 13 17 21 22 20 18 12 26 9 10 29 25 31 2 4 33 5 36 Resulting Magic Square Figure xi. either with the same number as that already in two of them or with the complementary number (ex. gr. in figure ix with a "1" or a "6") in any way, provided that there are an equal number of each of these numbers in the column, and subject also to the provisoes mentioned in the next paragraph but one. Fourth, the cells horizontally related to those in the first column are filled with the complementary numbers. Fifth, the remaining cells in the second and third columns are filled in an analogous way to that in which those in the first column were filled: and then the cells horizontally related to them are filled with the complementary numbers. The square so formed is necessarily magic in rows, columns, and diagonals. The second of the subsidiary squares (figure x) is constructed as follows. First, the cells in the leading diagonal are filled with the numbers 0, 6, 12, 18, 24, 30 placed in any order whatever that puts complementary numbers in complementary positions. Second, the cells horizontally related to them are filled respectively with the same numbers. Third, each of the remaining cells in the first horizontal row is filled either with the same number as that already in two of them or with the complementary number (ex. gr. in figure x with a "0" or a "30") in any way, provided (i) that there are an equal number of each of these numbers in the row, and (ii) that if any cell in the first row of figure ix and its vertically related cell are filled with complementary numbers, then the corresponding cell in the first row of figure x and its horizontally related cell must be occupied by the

same number* . Fourth, the cells vertically related to those in the first row are filled with the complementary numbers. Fifth, the remaining cells in the second and * The insertion of this step evades the necessity of constructing (as Montucla did) a third subsidiary square. 134 MAGIC SQUARES. [CH. V the third rows are filled in an analogous way to that in which those in the first row were filled: and then the cells vertically related to them are filled with the complementary numbers. The square so formed is necessarily magic in rows, columns, and diagonals. It remains to show that proviso (ii) in the third step described in the last paragraph can be satisfied always. In a doubly even square, that is, one in which n is divisible by 4, we need not have any complementary numbers in vertically related cells in the first subsidiary square unless we please, but even if we like to insert them they will not interfere with the satisfaction of this proviso. In the case of a singly even square, that is, one in which n is divisible by 2, but not by 4, we cannot satisfy the proviso if any horizontal row in the first square has all its vertically related squares, other than the two squares in the diagonals, filled with complementary numbers. Thus in the case of a singly even square it will be necessary in constructing the first square to take care in the third step that in every row at least one cell which is not in a diagonal shall have its vertically related cell filled with the same number as itself: this is always possible if n is greater than 2. The required magic square will be constructed if in each cell we place the sum of the numbers in the corresponding cells of the subsidiary squares, figures ix and x. The result of this is given in figure xi. The square is evidently magic. Also every number from 1 to 36 occurs once and only once, for the numbers from 1 to 6 and from 31 to 36 can occur only in the top or the bottom rows, and the method of construction ensures that the same number cannot occur twice. Similarly the numbers from 7 to 12 and from 25 to 30 occupy two other rows, and no number can occur twice; and so on. The square in figure i on page 121 may be constructed by the above rules; and the reader will have no difficulty in applying them to any other even square. Other Methods for Constructing any Magic Square. The above methods appear to me to be the simplest which have been proposed. There are however two other methods, of less generality, to which I will allude briefly in passing. Both depend on the principle that, if every number in a magic square is multiplied by some constant, and a constant is added to the product, the square will remain magic. The first method applies only to such squares as can be divided into smaller magic squares of some order higher than two. It depends on the fact that, if we know how to construct magic squares of the mth and nth CH. V] COMPOSITE AND BORDERED SQUARES.. 135 orders, we can construct one of the mnth order. For example, a square of 81 cells may be considered as composed of 9 smaller squares each containing 9 cells, and by filling the cells in each of these small squares in the same relative order and taking the small squares themselves in the same order, the square can be constructed easily. Such squares are

called composite magic squares. The second method, which was introduced by Frénicle, consists in surrounding a magic square with a border . Thus in figure xii on the following page the inner square is magic, and it is surrounded with a border in such a way that the whole square is also magic. In this manner from the magic square of the 3rd order we can build up successively squares of the orders 5, 7, 9, &c., that is, any odd magic square. Similarly from the magic square of the 4th order we can build up successively any higher even magic square. If we construct a magic square of the first n 2 numbers by bordering a magic square of (n − 2)2 numbers, the usual process is to reserve for the 4(n − 1) numbers in the border the first 2(n − 1) natural numbers and the last 2(n − 1) numbers. Now the sum of the numbers in each line of a square of the order (n − 2) is 1 2 (n − 2){(n − 2)2 + 1}, and the average is 1 2 {(n − 2)2 + 1}. Similarly the average number in a square of the nth order is 1 2 (n 2 +1). The difference of these is 2(n−1). We begin then by taking any magic square of the order (n − 2), and we add to every number in it 2(n − 1); this makes the average number 1 2 (n 2 + 1). The numbers reserved for the border occur in pairs, n 2 and 1, n 2−1 and 2, n 2 −2 and 3, &c., such that the average of each pair is 1 2 (n 2 +1), and they must be bordered on the square so that these numbers are opposite to one another. Thus the bordered square will be necessarily magic, provided that the sum of the numbers in two adjacent sides of the external border is correct. The arrangement of the numbers in the borders will be somewhat facilitated if the number n 2 + 1 − p (which has to be placed opposite to the number p) is denoted by p, but it is not worth while going into further details here. It will illustrate sufficiently the general method if I explain how the square in figure xii is constructed. A magic square of the third order is formed by De la Loubère's rule, and to every number in it 8 is added: the result is the inner square in figure xii. The numbers not used are 25 and 1, 24 and 2, 23 and 3, 22 and 4, 21 and 5, 20 and 6, 19 and 7, 18 and 8. The sum of each pair is 26, and obviously they must be 136 MAGIC SQUARES. [CH. V placed at opposite ends of any line. I believe that with a little patience a magic square of any order can be thus built up, and of course it will have the property that, if each border is successively stripped off, the square will still remain magic. Some examples are given by Violle. This is the method of construction commonly adopted by self-taught mathematicians, many 1 2 19 20 23 18 16 9 14 8 21 11 13 15 5 22 12 17 10 4 3 24 7 6 25 Bordered Magic Square. Figure xiii. of whom seem to think that the empirical formation of such squares is a valuable discovery. There are magic circles, rectangles, crosses, diamonds, stars, and other figures: also magic cubes, cylinders, and spheres. The theory of the construction of such figures is of no value, and I cannot spare the space to describe rules for forming them. Hyper-Magic Squares. In recent times attention has been mainly concentrated on the formation of magic squares with the imposition of

additional conditions; some of the resulting problems involve mathematical difficulties of a high order. Nasik Squares. In one species of hyper-magic squares the squares are formed so that the sums of the numbers along all the rows and columns, both diagonals, and all the broken diagonals are the same. In England these are called nasik squares or pan-diagonal magic squares: in France carrés diaboliques or carrés magiquement magiques. These squares were mentioned by De la Hire, Sauveur, and Euler; but the theory is mainly due to Mr A.H. Frost, who has expounded it in the memoirs mentioned in the footnote on page 123, and to M. Frolow, who treated it in two memoirs, St Petersburg, 1884, and Paris, 1886. Of course a nasik square can be divided by a vertical or horizontal cut and the pieces interchanged without affecting the magical property. By CH. V] MAGIC PENCILS. 137 one vertical and one horizontal transposition of this kind any number can be moved to any specified cell. A nasik square of the fourth order is represented in figure ii on page 121, and one of the fifth order is represented in figure xiii on the preceding page. Nasik squares of the order 6n±1 can be constructed by rules analogous to those given by De la Loubère, except that a knight's and not a bishop's move must be used in connecting cells filled by consecutive numbers and that for orders higher than five special rules for going from the cell occupied by the number kn to that occupied by the number kn + 1 have to be laid down. Doubly-Magic Squares. In another species of hyper-magic squares the problem is to construct a magic square of the nth order in such a way that if the number in each cell is replaced by its mth power the 5 31 35 60 57 34 8 30 19 9 53 46 47 56 18 12 16 22 42 39 52 61 27 1 63 37 25 24 3 14 44 50 26 4 64 49 38 43 13 23 41 51 15 2 21 28 62 40 54 48 20 11 10 17 55 45 36 58 6 29 32 7 33 59 A Doubly-Magic Square. Figure xiv. resulting square shall also be magic. Here for example (see figure xiv) is a magic square* of the eighth order, the sum of the numbers in each line being equal to 260, so constructed that if the number in each cell is replaced by its square the resulting square is also magic (the sum of the numbers in each line being equal to 11180). Magic Pencils. Hitherto I have concerned myself with numbers arranged in lines. By reciprocating the figures composed of the * See M. Coccoz in L'Illustration, May 29, 1897. 138 MAGIC SQUARES. [CH. V points on which the numbers are placed we obtain a collection of lines forming pencils, and, if these lines be numbered to correspond with the points, the pencils will be magic* . Thus, in a magic square of the nth order, we arrange n 2 consecutive numbers to form 2n + 2 lines, each containing n numbers so that the sum of the numbers in each line is the same. Reciprocally we can arrange n 2 lines, numbered consecutively to form 2n + 2 pencils, each containing n lines, so that in each pencil the sum of the numbers designating the lines is the same. For instance, figure xv represents a magic square of 64 consecutive 1 2 62 61 60 59 7 8 9 10 54 53 52 51 15 16 48 47 19 20 21 22 42 41 40 39 27 28 29 30 34 33 32 31 35 36 37 38 26 25 24 23 43 44 45 46 18 17 49 50 14 13 12 11 55 56 57 58 6 5 4 3

63 64 Figure xv. numbers arranged to form 18 lines, each of 8 numbers. Reciprocally, figure xvi represents 64 lines arranged to form 18 pencils, each of 8 lines. The method of construction is fairly obvious. The eight-rayed pencil, vertex O, is cut by two parallels perpendicular to the axis of the pencil, and all the points of intersection are joined cross-wise. This gives 8 pencils, with vertices A, B, . . . , H; 8 pencils, with vertices A' , . . . H' ; one pencil with its vertex at O; and one pencil with its vertex on the axis of the last-named pencil. The sum of the numbers in each of the 18 lines in figure xv is the same. To make figure xvi correspond to this we must number the lines in the pencil A from left to right, 1, 9, . . . , 57, following the order of the numbers in the first column of the square: the lines in pencil B must be numbered similarly to correspond to the numbers in the second column of the square, and so on. To prevent confusion in the figure I * See Magic-Reciprocals by G. Frankenstein, Cincinnati, 1875. CH. V] MAGIC PENCILS. 139 O AB C DEF G H A' H' Figure xvi. have not inserted the numbers, but it will be seen that the method of construction ensures that the sum of the 8 numbers which designate the lines in each of these 18 pencils is the same. We can proceed a step further, if the resulting figure is cut by two other parallel lines perpendicular to the axis, and if the points of their intersection with the cross-joins be joined cross-wise, these new cross-joins will intersect on the axis of the original pencil or on lines 140 MAGIC SQUARES. [CH. V perpendicular to it. The whole figure will now give 8 3 lines, arranged in 244 pencils each of 8 rays, and will be the reciprocal of a magic cube of the 8th order. If we reciprocate back again we obtain a representation in a plane of a magic cube. Magic Square Puzzles. Many empirical problems, closely related to magic squares, will suggest themselves; but most of them are more correctly described as ingenious puzzles than as mathematical recreations. The following will serve as specimens. Magic Card Square* . The first of these is the familiar problem of placing the sixteen court cards (taken out of a pack) in the form of a square so that no row, no column, and neither of the diagonals shall contain more than one card of each suit and one card of each rank. The solution presents no difficulty, and is indicated in figure xviii on the next page. Euler's Officers Problem† . A similar problem, proposed by Euler in 1779, consists in arranging, if it be possible, thirty-six officers taken from six regiments—the officers being in six groups, each consisting of six officers of equal rank, one drawn from each regiment; say officers of rank a, b, c, d, e, f, drawn from the 1st, 2nd, 3rd, 4th, 5th, and 6th regiments—in a solid square formation of six by six, so that each row and each file shall contain one and only one officer of each rank and one and only one officer from each regiment. The problem is insoluble. Extension of Euler's Problem. More generally we may investigate the arrangement on a chess-board, containing n 2 cells, of n 2 counters (the counters being divided into n groups, each group consisting of n counters of the same colour numbered consecutively 1, 2, . . . , n) so that each row and each column

shall contain no two counters of the same colour or marked with the same number. For instance, if n = 3, with three red counters a1, a2, a3, three white counters b1, b2, b3, and three black counters c1, c2, c3, we can satisfy the conditions by arranging them as in figure xvii on the facing page. If n = 4, then with counters a1, a2, a3, a4; b1, b2, b3, b4; c1, c2, * Ozanam, 1723 edition, vol. iv, p. 434. † Euler's Commentationes Arithmeticae, St Petersburg, 1849, vol ii, pp. 302–361. See also a paper by G. Tarry in the Comptes rendus of the French Association for the Advancement of Science, Paris, 1900, vol. ii, pp. 170–203; and various notes in L'Intermédiaire des mathématiciens, Paris, vol. iii, 1896, pp. 17, 90; vol. v, 1898, pp. 83, 176, 252, vol. vi, 1899, p. 251; vol. vii, 1900, pp. 14, 311. CH. V] MAGIC PUZZLES.. 141 c3, c4; d1, d2, d3, d4, we can arrange them as in figure xviii below. A solution when n = 5 is indicated in figure xix. a1 b2 c3 b2 c1 a2 c3 a3 b1 Figure xvii. a1 b2 c3 d4 c4 d3 a2 b1 d2 c1 b4 a3 b3 a4 d1 c2 Figure xviii. a1 b2 c3 d4 e5 b5 c1 d2 e3 a4 c4 d5 e1 a2 b3 d3 e4 a5 b1 c2 e2 a3 b4 c5 d1 Figure xix. The problem is soluble if n is odd or if n is of the form 4m. If solutions when n = a and when n = b are known, a solution when n = ab can be written down at once. The theory is closely connected with that of magic squares and need not be here discussed further. Magic Domino Squares. Analogous problems can be made with dominoes. An ordinary set of dominoes, ranging from double zero to double six, contains 28 dominoes. Each domino is a rectangle formed by fixing two small square blocks together side by side: of these 56 blocks, eight are blank, on each of eight of them is one pip, on each of another eight of them are two pips, and so on. It is required to arrange the dominoes so that the 56 blocks form a square of 7 by 7 bordered by one line of 7 blank squares and so that the sum of the pips in each row, each column, and in the two diagonals of the square is equal to 24. A solution* is given on the following page. Similarly, a set of dominoes, ranging from double zero to double n, contains 1 2 (n + 1)(n + 2) dominoes and therefore (n + 1)(n + 2) blocks. Can these dominoes be arranged in the form of a square of (n + 1)2 cells, bordered by a row of blanks, so that the sum of the pips in each row, each column, and in the two diagonals of the square is equal to 1 2 n(n + 2)? Magic Coin Squares† . There are somewhat similar questions concerned with coins. Here is one applicable to a square of the third order divided into nine cells, as in figure xvii above. If a five-shilling piece is placed in the middle cell c1 and a florin in the cell below it, namely, in a3 it is required to place the fewest possible current English coins in * See L'Illustration, July 10, 1897. † See The Strand Magazine, London, December, 1896, pp. 720, 721. 142 MAGIC SQUARES. [CH. V Magic Domino Square. the remaining seven cells so that in each cell there is at least one coin, so that the total value of the coins in every cell is different, and so that the sum of the values of the coins in each row, column, and diagonal is fifteen shillings: it will be found that thirteen additional coins will suffice. A similar problem is to place ten current English postage stamps, all but two

being different, in the nine cells so that the sum of the values of the stamps in each row, column, and diagonal is ninepence. CHAPTER VI. UNICURSAL PROBLEMS. I propose to consider in this chapter some problems which arise out of the theory of unicursal curves. I shall commence with Euler's Problem and Theorems, and shall apply the results briefly to the theories of Mazes and Geometrical Trees. The reciprocal unicursal problems of the Hamilton Game and the Knight's Path on a Chess-board will be discussed in the latter half of the chapter. Euler's Problem. Euler's problem has its origin in a memoir† presented by him in 1736 to the St Petersburg Academy, in which he solved a question then under discussion as to whether it was possible to take a walk in the town of Königsberg in such a way as to cross every bridge in it once and only once. The town is built near the mouth of the river Pregel, which there takes the form indicated on the following page and includes the island of Kneiphof. In 1759 there were (and according to Baedeker there are still) seven bridges in the positions shown in the diagram, and it is easily seen that with such an arrangement the problem is insoluble. Euler however did not confine himself to the case of Königsberg, but discussed the general problem of any number of islands connected in any way by bridges. It is evident that the question will not be affected if † Solutio problematis ad Geometriam situs pertinentis, Commentarii Academiae Scientiarum Petropolitanae for 1736, St Petersburg, 1741, vol. viii, pp. 128–140. This has been translated into French by M. Ch. Henry; see Lucas, vol. i, part 2, pp. 21–33. 143 144 UNICURSAL PROBLEMS. [CH. VI we suppose the islands to diminish to points and the bridges to lengthen out. In this way we ultimately obtain a geometrical figure or network. In the Königsberg problem this figure is of the shape indicated below, the areas being represented by the points A, B, C, D, and the bridges being represented by the lines l, m, n, p, q, r, s. A B C D s r l qp mn Euler's problem consists therefore in finding whether a given geometrical figure can be described by a point moving so as to traverse every line in it once and only once. A more general question is to determine how many strokes are necessary to describe such a figure so that no line is traversed twice: this is covered by the rules hereafter given. The figure may be either in three or in two dimensions, and it may be represented by lines, straight, curved, or tortuous, joining a number of given points, or a model may be constructed by taking a number of rods or pieces of string furnished at each end with a hook so as to allow of any number of them being connected together at one point. The theory of such figures is included as a particular case in the CH. VI] EULER'S PROBLEM. 145 propositions proved by Listing in his Topologie* . I shall, however, adopt here the methods of Euler, and I shall begin by giving some definitions, as it will enable me to put the argument in a more concise form. A node (or isle) is a point to or from which lines are drawn. A branch (or bridge or path) is a line connecting two consecutive nodes. An end (or hook) is the point at each termination of a branch. The order of a node is

the number of branches which meet at it. A node to which only one branch is drawn is a free node or a free end. A node at which an even number of branches meet is an even node: evidently the presence of a node of the second order is immaterial. A node at which an odd number of branches meet is an odd node. A figure is closed if it has no free end: such a figure is often called a closed network. A route consists of a number of branches taken in consecutive order and so that no branch is traversed twice. A closed route terminates at the point from which it started. A figure is described unicursally when the whole of it is traversed in one route. The following are Euler's results. (i) In a closed network the number of odd nodes is even. (ii) A figure which has no odd node can be described unicursally, in a re-entrant route, by a moving point which starts from any point on it. (iii) A figure which has two and only two odd notes can be described unicursally by a moving point which starts from one of the odd nodes and finishes at the other. (iv) A figure which has more than two odd nodes cannot be described completely in one route; to which Listing added the corollary that a figure which has 2n odd nodes, and no more, can be described completely in n separate routes. I now proceed to prove these theorems. First. The number of odd nodes in a closed network is even. Suppose the number of branches to be b. Therefore the number of hooks is 2b. Let kn be the number of nodes of the nth order. Since a node of the nth order is one at which n branches meet, there are n hooks there. Also since the figure is closed, n cannot be less than 2. ∴ 2k2 + 3k3 + 4k4 + · · · + nkn + · · · = 2b . Hence 3k3 + 5k5 + · · · is even. ∴ k3 + k5 + · · · is even. Second. A figure which has no odd node can be described unicursally in a re-entrant route. * Die Studien, Göttingen, 1847, part x. See also Tait on Listing's Topologie, Philosophical Magazine, London, January, 1884, series 5, vol. xvii, pp. 30–46. 146 UNICURSAL PROBLEMS. [CH. VI Since the route is to be re-entrant it will make no difference where it commences. Suppose that we start from a node A. Every time our route takes us through a node we use up one hook in entering it and one in leaving it. There are no odd nodes, therefore the number of hooks at every node is even: hence, if we reach any node except A, we shall always find a hook which will take us into a branch previously untraversed. Hence the route will take us finally to the node A from which we started. If there are more than two hooks at A, we can continue the route over one of the branches from A previously untraversed, but in the same way as before we shall finally come back to A. It remains to show that we can arrange our route so as to make it cover all the branches. Suppose each branch of the network to be represented by a string with a hook at each end, and that at each node all the hooks there are fastened together. The number of hooks at each node is even, and if they are unfastened they can be re-coupled together in pairs, the arrangement of the pairs being immaterial. The whole network will then form one or more closed curves, since now each node consists merely of two ends hooked together. If this random coupling gives us one single

curve then the proposition is proved; for starting at any point we shall go along every branch and come back to the initial point. But if this random coupling produces anywhere an isolated loop, L, then where it touches some other loop, M, say at the node P, unfasten the four hooks there (viz. two of the loop L and two of the loop M) and re-couple them in any other order: then the loop L will become a part of the loop M. In this way, by altering the couplings, we can transform gradually all the separate loops into parts of only one loop. For example, take the case of three isles, A, B, C, each connected with both the others by two bridges. The most unfavourable way of recoupling the ends at A, B, C would be to make ABA, ACA, and BCB separate loops. The loops ABA and ACA are separate and touch at A; hence we should re-couple the hooks at A so as to combine ABA and ACA into one loop ABACA. Similarly, by re-arranging the couplings of the four hooks at B, we can combine the loop BCB with ABACA and thus make only one loop. I infer from Euler's language that he had attempted to solve the problem of giving a practical rule which would enable one to describe such a figure unicursally without knowledge of its form, but that in this CH. VI] EULER'S PROBLEM. 147 B C A he was unsuccessful. He however added that any geometrical figure can be described completely in a single route provided each part of it is described twice and only twice, for, if we suppose that every branch is duplicated, there will be no odd nodes and the figure is unicursal. In this case any figure can be described completely without knowing its form: rules to effect this are given below. Third. A figure which has two and only two odd nodes can be described unicursally by a point which starts from one of the odd nodes and finishes at the other odd node. This at once reduces to the second theorem. Let A and Z be the two odd nodes. First, suppose that Z is not a free end. We can, of course, take a route from A to Z; if we imagine the branches in this route to be eliminated, it will remove one hook from A and make it even, will remove two hooks from every node intermediate between A and Z and therefore leave each of them even, and will remove one hook from Z and therefore will make it even. All the remaining network is now even: hence, by Euler's second proposition, it can be described unicursally, and, if the route begins at Z, it will end at Z. Hence, if these two routes are taken in succession, the whole figure will be described unicursally, beginning at A and ending at Z. Second, if Z is a free end, then we must travel from Z to some node, Y , at which more than two branches meet. Then a route from A to Y which covers the whole figure exclusive of the path from Y to Z can be determined as before and must be finished by travelling from Y to Z. Fourth. A figure having 2n odd nodes, and no more, can be described completely in n separate routes. If any route starts at an odd node, and if it is continued until it reaches a node where no fresh path is open to it, this latter node must be an odd one. For every time we enter an even node there is necessarily 148 UNICURSAL PROBLEMS. [CH. VI a way out of it; and similarly every time we go through an odd node we use up one

hook in entering and one hook in leaving, but whenever we reach it as the end of our route we use only one hook. If this route is suppressed there will remain a figure with 2n − 2 odd nodes. Hence n such routes will leave one or more networks with only even nodes. But each of these must have some node common to one of the routes already taken and therefore can be described as a part of that route. Hence the complete passage will require n and not more than n routes. It follows, as stated by Euler, that, if there are more than two odd nodes, the figure cannot be traversed completely in one route. The Königsberg bridges lead to a network with four odd nodes; hence, by Euler's fourth proposition, it cannot be described unicursally in a single journey, though it can be traversed completely in two separate routes. The first and second diagrams figured below contain only even nodes, and therefore each of them can be described unicursally. The first of these—a re-entrant pentagon—was one of the Pythagorean symbols. The other is the so-called sign-manual of Mohammed, said to have been originally traced in the sand by the point of his scimetar without taking the scimetar off the ground or retracing any part of the figure—which, as it contains only even nodes, is possible. The third diagram is taken from Tait's article: it contains only two odd nodes, and therefore can be described unicursally if we start from one of them and finish at the other. As other examples I may note that the geometrical figure formed by taking a (2n + 1)gon and joining every angular point with every other angular point is unicursal. On the other hand a chess-board, divided as usual by straight lines into 64 cells, has 28 odd nodes and CH. VI] MAZES AND LABYRINTHS.. 149 53 even nodes: hence it would require 14 separate pen-strokes to trace out all the boundaries without going over any more than once. Again, the diagram on page 102 has 20 odd nodes and therefore would require 10 separate pen-strokes to trace it out. It is well known that a curve which has as many nodes as is consistent with its degree is unicursal. Mazes. Everyone has read of the labyrinth of Minos in Crete and of Rosamund's Bower. A few modern mazes exist here and there—notably one, which is a very poor specimen of its kind, at Hampton Court—and in one of these, or at any rate on a drawing of one, most of us have threaded our way to the interior. I proceed now to consider the manner in which any such construction may be completely traversed even by one who is ignorant of its plan. The theory of the description of mazes is included in Euler's theorems given above. The paths in the maze are what previously we have termed branches, and the places where two or more paths meet are nodes. The entrance to the maze, the end of a blind alley, and the centre of the maze are free ends and therefore odd nodes. If the only odd nodes are the entrance to the maze and the centre of it–which will necessitate the absence of all blind alleys–the maze can be described unicursally. This follows from Euler's third proposition. Again, no matter how many odd nodes there may be in a maze, we can always find a route which will take us from the entrance to the centre without retracing our steps, though such

a route will take us through only a part of the maze. But in neither of the cases mentioned in this paragraph can the route be determined without a plan of the maze. A plan is not necessary, however, if we make use of Euler's suggestion, and suppose that every path in the maze is duplicated. In this case we can give definite rules for the complete description of the whole of any maze, even if we are entirely ignorant of its plan. Of course to walk twice over every path in a labyrinth is not the shortest way of arriving at the centre, but, if it is performed correctly, the whole maze is traversed, the arrival at the centre at some point in the course of the route is certain, and it is impossible to lose one's way. I need hardly explain why the complete description of such a duplicated maze is possible, for now every node is even, and hence, by Euler's second proposition, if we begin at the entrance we can traverse 150 UNICURSAL PROBLEMS. [CH. VI the whole maze; in so doing we shall at some point arrive at the centre, and finally shall emerge at the point from which we started. This description will require us to go over every path in the maze twice, and as a matter of fact the two passages along any path will be always made in opposite directions. If a maze is traced on paper, the way to the centre is generally obvious, but in an actual labyrinth it is not so easy to find the correct route unless the plan is known. In order to make sure of describing a maze without knowing its plan it is necessary to have some means of marking the paths which we traverse and the direction in which we have traversed them—for example, by drawing an arrow at the entrance and end of every path traversed, or better perhaps by marking the wall on the right-hand side, in which case a path may not be entered when there is a mark on each side of it. If we can do this, and if when a node is reached, we take, if it be possible, some path not previously used, or, if no other path is available, we enter on a path already traversed once only, we shall completely traverse any maze in two dimensions* . Of course a path must not be traversed twice in the same direction, a path already traversed twice (namely, once in each direction) must not be entered, and at the end of a blind alley it is necessary to turn back along the path by which it was reached. I think most people would understand by a maze a series of interlacing paths through which some route can be obtained leading to a space or building at the centre of the maze. I believe that few, if any, mazes of this type existed in classical or medieval times. One class of what the ancients called mazes or labyrinths seems to have comprised any complicated building with numerous vaults and passages† . Such a building might be termed a labyrinth, but it is not what is usually understood by the word. The above rules would enable anyone to traverse the whole of any structure of this kind. I do not know if there are any accounts or descriptions of Rosamund's Bower * See Le problème des labyrinthes by G. Tarry, Nouvelles Annales de mathématiques, May, 1895, series 3, vol. xiv. † For instance, see the descriptions of the labyrinth at Lake Moeris given by Herodotus, bk. ii, c. 148; Strabo, bk. xvii, c. 1, art. 37; Diodorus,

bk. i, cc. 61, 66; and Pliny, Hist. Nat., bk. xxxvi, c. 13, arts. 84–89. On these and other references see A. Wiedemann, Herodots zweites Buch, Leipzig, 1890, p. 522 et seq. See also Virgil, Aeneid, bk. v, c. v, 588; Ovid, Met., bk. viii, c. 5, 159; Strabo, bk. viii, c. 6. CH. VI] MAZES AND LABYRINTHS.. 151 other than those by Drayton, Bromton, and Knyghton: in the opinion of some, these imply that the bower was merely a house, the passages in which were confusing and ill-arranged. Another class of ancient mazes consisted of a tortuous path confined to a small area of ground and leading to a place or shrine in the centre* . This is a maze in which there is no chance of taking a wrong turning; but, as the whole area can be occupied by the windings of one path, the distance to be traversed from the entrance to the centre may be considerable, even though the piece of ground covered by the maze is but small. The traditional form of the labyrinth constructed for the Minotaur is a specimen of this class. It was delineated on the reverses of the coins of Cnossus, specimens of which are not uncommon; one form of it is indicated in the accompanying diagram (figure i). The design really is the same as that drawn in figure ii, as can be easily seen by bending round a circle the rectangular figure there given. Mr Inwards has suggested† that this design on the coins of Cnossus may be a survival from that on a token given by the priests as a clue to Figure i. Figure ii. the right path in the labyrinth there. Taking the circular form of the design shown above he supposed each circular wall to be replaced by two equidistant walls separated by a path, and thus obtained a maze to which the original design would serve as the key. The route thus indicated may be at once obtained by noticing that when a node is reached (i.e. a point where there is a choice of paths) the path to be * On ancient and medieval labyrinths—particularly of this kind—see an article by Mr E. Trollope in The Archaeological Journal, 1858, vol. xv, pp. 216–235, from which much of the historical information given above is derived † Knowledge, London, October, 1892. 152 UNICURSAL PROBLEMS. [CH. VI taken is that which is next but one to that by which the node was approached. This maze may be also threaded by the simple rule of always following the wall on the right-hand side or always that on the left-hand side. The labyrinth may be somewhat improved by erecting a few additional barriers, without affecting the applicability of the above rules, but it cannot be made really difficult. This makes a pretty toy, but though the conjecture on which it is founded is ingenious it must be regarded as exceedingly improbable. Another suggestion is that the curved line on the reverse of the coins indicated the form of the rope held by those taking part in some rhythmic dance; while others consider that the form was gradually evolved from the widely prevalent svastika. Copies of the maze of Cnossus were frequently engraved on Greek and Roman gems; similar but more elaborate designs are found in numerous Roman mosaic pavements* . A copy of the Cretan labyrinth was embroidered on many of the state robes of the later Emperors, and, apparently thence, was copied on to the walls and

floors of various churches† . At a later time in Italy and in France these mural and pavement decorations were developed into scrolls of great complexity, but consisting, as far as I know, always of a single line. Some of the best specimens now extant are on the walls of the cathedrals at Lucca, Aix in Provence, and Poitiers; and on the floors of the churches of Santa Maria in Trastevere at Rome, San Vitale at Ravenna, Notre Dame at St Omer, and the cathedral at Chartres. It is possible that they were used to represent the journey through life as a kind of pilgrim's progress. In England these mazes were usually, perhaps always, cut in the turf adjacent to some religious house or hermitage: and there are some slight reasons for thinking that, when traversed as a religious exercise, a pater or ave had to be repeated at every turning. After the Renaissance, such labyrinths were frequently termed Troy-towns or Julian's bowers. Some of the best specimens, which are still extant, are those at Rockliff Marshes, Cumberland; Asenby, Yorkshire; Alkborough, Lincolnshire; Wing, Rutlandshire; Boughton-Green, Northamptonshire; Comberton, Cambridgeshire; Saffron Walden, Essex; and Chilcombe, near Winchester. The modern maze seems to have been introduced—probably from Italy—during the Renaissance, and many of the palaces and large * See ex. gr. Breton's Pompeia, p. 303. † Ozanam, Graphia aureae urbis Romae, pp. 92, 178. CH. VI] MAZES AND LABYRINTHS.. 153 houses built in England during the Tudor and the Stuart periods had labyrinths attached to them. Those adjoining the royal palaces at Southwark, Greenwich, and Hampton Court were particularly well known from their vicinity to the capital. The last of these was designed by London and Wise in 1690, for William III, who had a fancy for such conceits: a plan of it is given in various guide-books. For the majority Maze at Hampton Court. of the sight-seers who enter, it is sufficiently elaborate; but it is an indifferent construction, for it can be described completely by always following the hedge on one side (either the right hand or the left hand), and no node is of an order higher than three. Unless at some point the route to the centre forks and subsequently the two forks reunite, forming a loop in which the centre of the maze is situated, the centre can be reached by the rule just given, namely, by following the wall on one side—either on the right hand or on the left hand. No labyrinth is worthy of the name of a puzzle which can be threaded in this way. Assuming that the path forks as described above, the more numerous the nodes and the higher their order the more difficult will be the maze, and the difficulty might be increased considerably by using bridges and tunnels so as to construct a labyrinth in three dimensions. In an ordinary garden and on a small piece of ground, often of an inconvenient shape, it is not easy to make a maze which fulfils these conditions. Here on the following page is a plan of one which I put up in my own garden on a plot of ground which would not allow of more than 36 by 23 paths, but it will be noticed that none of the nodes are of a high order. 154 UNICURSAL PROBLEMS. [CH. VI Geometrical Trees. Euler's original investigations were confined to a

closed network. In the problem of the maze it was assumed that there might be any number of blind alleys in it, the ends of which formed free nodes. We may now progress one step farther, and suppose that the network or closed part of the figure diminishes to a point. This last arrangement is known as a tree. The number of unicursal descriptions necessary to completely describe a tree is called the base of the ramification. We can illustrate the possible form of these trees by rods, having a hook at each end. Starting with one such rod, we can attach at either end one or more similar rods. Again, on any free hook we can attach one or more similar rods, and so on. Every free hook, and also every point where two or more rods meet, are what hitherto we have called nodes. The rods are what hitherto we have termed branches or paths. The theory of trees—which already plays a somewhat important part in certain branches of modern analysis, and possibly may contain the key to certain chemical and biological theories—originated in a memoir by Cayley* , written in 1856. The discussion of the theory has * Philosophical Magazine, March, 1857, series 4, vol. xiii, pp. 172–176; or Collected Works, Cambridge, 1890, vol. iii, no. 203, pp. 242–346: see also the paper on double partitions, Philosophical Magazine, November, 1860, series 4, vol. xx, pp. 337–341. On the number of trees with a given number of nodes, see the CH. VI] THE HAMILTONIAN GAME. 155 been analytical rather than geometrical. I content myself with noting the following results. The number of trees with n given nodes is n n−2 . If An is the number of trees with n branches, and Bn the number of trees with n free branches which are bifurcations at least, then (1 − x) −1 (1 − x 2) −A1 (1 − x 3) −A2 · · · = 1 + A1x + A2x 2 + A3x 3 + · · · , (1 − x) −1 (1 − x 2) −B2 (1 − x 3) −B3 · · · = 1 + x + 2B2x 2 + 2B3x 3 + · · · . Using these formulae we can find successively the values of A1, A2, . . . , and B1, B2, ... The values of An when n = 2, 3, 4, 5, 6, 7, are 2, 4, 9, 20, 48, 115; and of Bn are 1, 2, 5, 12, 33, 90. I turn next to consider some problems where it is desired to find a route which will pass once and only once through each node of a given geometrical figure. This is the reciprocal of the problem treated in the first part of this chapter, and is a far more difficult question. I am not aware that the general theory has been considered by mathematicians, though two special cases—namely, the Hamiltonian (or Icosian) Game and the Knight's Path on a Chess-Board—have been treated in some detail; and I confine myself to a discussion of these. The Hamiltonian Game. The Hamiltonian Game consists in the determination of a route along the edges of a regular dodecahedron which will pass once and only once through every angular point. Sir William Hamilton* , who invented this game—if game is the right term for it—denoted the twenty angular points on the solid by letters which stand for various towns. The thirty edges constitute the only possible paths. The inconvenience of using a solid is considerable, and the dodecahedron may be represented conveniently in perspective by a flat board marked as shown in the first of the annexed diagrams. The Quarterly Journal of

Mathematics, London, 1889, vol. xxiii, pp. 376–378. The connection with chemistry was first pointed out in Cayley's paper on isomers, Philosophical Magazine, June, 1874, series 4, vol. xlvii, pp. 444–447, and was treated more fully in his report on trees to the British Association in 1875, Reports, pp. 257–305. * See Quarterly Journal of Mathematics, London, 1862, vol. v, p. 305; or Philosophical Magazine, January, 1884, series 5, vol. xvii, p. 42; also Lucas, vol. ii, part vii. 156 UNICURSAL PROBLEMS. [CH. VI second and third diagrams will answer our purpose equally well and are easier to draw. A G J L N P Q R S T B C D E F H M K O U A B C D E F G H J K L M N O P Q R S T U A B C D E F U The first problem is go "all round the world," that is, starting from any town, to go to every other town once and only once and to return to the initial town; the order of the n towns to be first visited being assigned, where n is not greater than five. Hamilton's rule for effecting this was given at the meeting in 1857 of the British Association at Dublin. At each angular point there are three and only three edges. Hence, if we approach a point by one edge, the only routes open to us are one to the right, denoted by r, and one to the left, denoted by l. It will be found that the operations indicated on opposite sides of the following equalities are equivalent, lr2 l = rlr, rl2 r = lrl, lr3 l = r 2 , rl3 r = l 2 . Also the operation l 5 or r 5 brings us back to the initial point: we may represent this by the equations l 5 = 1, r5 = 1 . To solve the problem for a figure having twenty angular points we must deduce a relation involving twenty successive operations, the total effect of which is equal to unity. By repeated use of the relation l 2 = rl3 r we see that 1 = l 5 = l 2 l 3 = (rl3 r)l 3 = {rl3 } 2 = {r(rl3 r)l} 2 = {r 2 l 3 rl} 2 = {r 2 (rl3 r)lrl} 2 = {r 3 l 3 rlrl} 2 . Therefore {r 3 l 3 (rl) 2 } 2 = 1 . . . . . (i), and similarly {l 3 r 3 (lr) 2 } 2 = 1 . . . . . (ii). CH. VI] THE HAMILTONIAN GAME. 157 Hence on a dodecahedron either of the operations r r r l l l r l r l r r r l l l r l r l . . . . . (i), l l l r r r l r l r l l l r r r l r l r . . . . . (ii), indicates a route which takes the traveller through every town, The arrangement is cyclical, and the route can be commenced at any point in the series of operations by transferring the proper number of letters from one end to the other. The point at which we begin is determined by the order of certain towns which is given initially. Thus, suppose that we are told that we start from F and then successively go to B, A, U, and T, and we want to find a route from T through all the remaining towns which will end at F. If we think of ourselves as coming into F from G, the path F B would be indicated by l, but if we think of ourselves as coming into F from E, the path F B would be indicated by r. The path from B to A is indicated by l, and so on. Hence our first paths are indicated either by l l l r or by r l l r. The latter operation does not occur either in (i) or in (ii), and therefore does not fall within our solutions. The former operation may be regarded either as the 1st, 2nd, 3rd, and 4th steps of (ii), or as the 4th, 5th, 6th, and 7th steps of (i). Each of these leads to a route which satisfies the problem. These routes are F B A U T P O N C D E J K L M Q R S H G F , and F B A U T S R K L M Q P O N C D E J H G F . It is convenient to

make a mark or to put down a counter at each corner as soon as it is reached, and this will prevent our passing through the same town twice. A similar game may be played with other solids provided that at each angular point three and only three edges meet. Of such solids a tetrahedron and a cube are the simplest instances, but the reader can make for himself any number of plane figures representing such solids similar to those drawn on the preceding page. Some of these were indicated by Hamilton. In all such cases we must obtain from the formulae analogous to those given above cyclical relations like (i) or (ii) there given. The solution will then follow the lines indicated above. This method may be used to form a rule for describing any maze in which no node is of an order higher than three. 158 UNICURSAL PROBLEMS. [CH. VI For solids having angular points where more than three edges meet—such as the octahedron where at each angular point four edges meet, or the icosahedron where at each angular point five edges meet— we should at each point have more than two routes open to us; hence (unless we suppress some of the edges) the symbolical notation would have to be extended before it could be applied to these solids. I offer the suggestion to anyone who is desirous of inventing a new game. Another and a very elegant solution of the Hamiltonian dodecahedron problem has been given by M. Hermary. It consists in unfolding the dodecahedron into its twelve pentagons, each of which is attached to the preceding one by only one of its sides; but the solution is geometrical, and not directly applicable to more complicated solids. Hamilton suggested as another problem to start from any town, to go to certain specified towns in an assigned order, then to go to every other town once and only once, and to end the journey at some given town. He also suggested the consideration of the way in which a certain number of towns should be blocked so that there was no passage through them, in order to produce certain effects. These problems have not, so far as I know, been subjected to mathematical analysis. Knight's Path on a Chess-Board. Another geometrical problem on which a great deal of ingenuity has been expended, and of a kind somewhat similar to the Hamiltonian game, consists in moving a knight on a chess-board in such a manner that it shall move successively on to every cell* once and only once. The literature on this subject is so extensive† that I make no pretence to give a full account of the various methods for solving the problem, and I shall content myself by putting together a few notes on some of the solutions I have come across, particularly on those due to De Moivre, Euler, Vandermonde, Warnsdorff, and Roget. On a board containing an even number of cells the path may or may not be re-entrant, but on a board containing an odd number of * The 64 small squares into which a chess-board is divided are termed cells. † For a bibliography see A. van der Linde, Geschichte und Literatur des Schachspiels, Berlin, 1874, vol. ii, pp. 101–111. On the problem see a memoir by P. Volpicelli in Atti della Reale Accademia dei Lincei, Rome, 1872, vol. xxv, pp. 87–162: also Applications de l'Analyse

Mathématique au Jeu des échecs, by C.F. de Jaenisch, 3 vols., St Petersburg, 1862–3; and General Parmentier, Association Française pour l'avancement des Sciences, 1891, 1892, 1894. CH. VI] KNIGHT'S PATH ON A CHESS-BOARD. 159 cells it cannot be re-entrant. For, if a knight begins on a white cell, its first move must take it to a black cell, the next to a white cell, and so on. Hence, if its path passes through all the cells, then on a board of an odd number of cells the last move must leave it on a cell of the same colour as that on which it started, and therefore these cells cannot be connected by one move. The earliest solutions of which I have any knowledge are those given about the end of the seventeenth century by De Montmort and De Moivre* . They apply to the ordinary chess-board of 64 cells, and depend on dividing (mentally) the board into an inner square containing sixteen cells surrounded by an outer ring of cells two deep. If initially the knight is placed on a cell in the outer ring, it moves round that ring always in the same direction so as to fill it up completely—only going into the inner square when absolutely necessary. When the outer ring is filled up the order of the moves required for filling the remaining cells presents but little difficulty. If initially the knight is placed on the inner square the process must be reversed. The method can be applied to square and rectangular boards of all sizes. It is illustrated sufficiently by De Moivre's solution which is given below, where the 34 49 22 11 36 39 24 1 21 10 35 50 23 12 37 40 48 33 62 57 38 25 2 13 9 20 51 54 63 60 41 26 32 47 58 61 56 53 14 3 19 8 55 52 59 64 27 42 46 31 6 17 44 29 4 15 7 18 45 30 5 16 43 28 De Moivre's Solution. 30 21 6 15 28 19 7 16 29 20 5 14 22 31 8 35 18 27 9 36 17 26 13 4 32 23 2 11 34 25 1 10 33 24 3 12 Euler's Thirty-six Cell Solution. numbers indicate the order in which the cells are occupied successively. I place by its side a somewhat similar re-entrant solution, due to Euler, for a board of 36 cells. If a chess-board is used it is convenient to place a counter on each cell as the knight leaves it. * I do not know where they were published originally; they were quoted by Ozanam and Montucla, see Ozanam, 1803 edition, vol. i, p. 178; 1840 edition, p. 80. 160 UNICURSAL PROBLEMS. [CH. VI The next serious attempt to deal with the subject was made by Euler* in 1759: it was due to a suggestion made by L. Bertrand of Geneva, who subsequently (in 1778) issued an account of it. This method is applicable to boards of any shape and size, but in general the solutions to which it leads are not symmetrical and their mutual connexion is not apparent. Euler commenced by moving the knight at random over the board until it has no move open to it. With care this will leave only a few cells not traversed: denote them by a, b, ... His method consists in establishing certain rules by which these vacant cells can be interpolated into various parts of the circuit, and also by which the circuit can be made re-entrant. The following example, mentioned by Legendre as one of exceptional difficulty, illustrates the method. Suppose that we have formed 55 58 29 40 27 44 19 22 60 39 56 43 30 21 26 45 57 54 59 28 41 18 23 20 38 51 42 31 8 25 46 17 53 32 37 a 47 16 9 24 50 3 52

33 36 7 12 15 1 34 5 48 b 14 c 10 4 49 2 35 6 11 d 13 Figure i. 22 25 50 39 52 35 60 57 27 40 23 36 49 58 53 34 24 21 26 51 38 61 56 59 41 28 37 48 3 54 33 62 20 47 42 13 32 63 4 55 29 16 19 46 43 2 7 10 18 45 14 31 12 9 64 5 15 30 17 44 1 6 11 8 Figure ii. Example of Euler's Method. the route given in figure i; namely, 1, 2, 3, . . . , 59, 60; and that there are four cells left untraversed, namely, a, b, c, d. We begin by making the path 1 to 60 re-entrant. The cell 1 commands a cell p, where p is 32, 52, or 2. The cell 60 commands a cell q, where q is 29, 59, or 51. Then, if any of these values of p and q differ by unity, we can make the route re-entrant. This is the case here if p = 52, q = 51. Thus the cells 1, 2, 3, . . . , 51; 60, 59, . . . , 52 form a * Mémoires de Berlin for 1759, Berlin, 1766, pp. 310–337; or Commentationes Arithmeticae Collectae, St Petersburg, 1849, vol. i, pp. 337–355. CH. VI] KNIGHT'S PATH ON A CHESS-BOARD. 161 re-entrant route of 60 moves. Hence, if we replace the numbers 60, 59, . . . , 52 by 52, 53, . . . , 60, the steps will be numbered consecutively. I recommend the reader who wishes to follow the subsequent details of Euler's argument to construct this square on a piece of paper before proceeding further. Next, we add the cells a, b, d to this route. In the new diagram of 60 cells formed as above the cell a commands the cells there numbered 51, 53, 41, 25, 7, 5, and 3. It is indifferent which of these we select: suppose we take 51. Then we must make 51 the last cell of the route of 60 cells, so that we can continue with a, b, d. Hence, if the reader will add 9 to every number on the diagram he has constructed, and then replace 61, 62, . . . , 69 by 1, 2, . . . , 9, he will have a route which starts from the cell occupied originally by 60, the 60th move is on to the cell occupied originally by 51, and the 61st, 62nd, 63rd moves will be on the cells a, b, d respectively. It remains to introduce the cell c. Since c commands the cell now numbered 25, and 63 commands the cell now numbered 24, this can be effected in the same way as the first route was made re-entrant. In fact the cells numbered 1, 2, . . . , 24; 63, 62, . . . , 25, c form a knight's path. Hence we must replace 63, 62, . . . , 25 by the numbers 25, 26, . . . , 63, and then we can fill up c with 64. We have now a route which covers the whole board. Lastly, it remains to make this route re-entrant. First, we must get the cells 1 and 64 near one another. This can be effected thus. Take one of the cells commanded by 1, such as 28, then 28 commands 1 and 27. Hence the cells 64, 63, . . . , 28; 1, 2, . . . , 27 form a route; and this will be represented in the diagram if we replace the cells numbered 1, 2, . . . , 27 by 27, 26, . . . , 1. The cell now occupied by 1 commands the cells 26, 38, 54, 12, 14, 16, 28; and the cell occupied by 64 commands the cells 13, 43, 63, 55. The cells 13 and 14 are consecutive, and therefore the cells 64, 63, . . . , 14; 1, 2, . . . , 13 form a route. Hence we must replace the numbers 1, 2, . . . , 13 by 13, 12, . . . , 1, and we obtain a re-entrant route covering the whole board, which is represented in the second of the diagrams given on the facing page. Euler showed how seven other re-entrant routes can be deduced from any given re-entrant route. It is not difficult to

apply the method so as to form a route which begins on one given cell and ends on any other given cell. 162 UNICURSAL PROBLEMS. [CH. VI Euler next investigated how his method could be modified so as to allow of the imposition of additional restrictions. An interesting example of this kind is where the first 32 moves are confined to one half of the board. One solution of this is delineated below. The order of the first 32 moves can be determined by Euler's 58 43 60 37 52 41 62 35 49 46 57 42 61 36 53 40 44 59 48 51 38 55 34 63 47 50 45 56 33 64 39 54 22 7 32 1 24 13 18 15 31 2 23 6 19 16 27 12 8 21 4 29 10 25 14 17 3 30 9 20 5 28 11 26 Euler's Half-board Solution. 50 45 62 41 60 39 54 35 63 42 51 48 53 36 57 38 46 49 44 61 40 59 34 55 43 64 47 52 33 56 37 58 26 5 24 1 20 15 32 11 23 2 27 8 29 12 17 14 6 25 4 21 16 19 10 31 3 22 7 28 9 30 13 18 Roget's Half-board Solution. method. It is obvious that, if to the number of each such move we add 32, we shall have a corresponding set of moves from 33 to 64 which would cover the other half of the board; but in general the cell numbered 33 will not be a knight's move from that numbered 32, nor will 64 be a knight's move from 1. Euler however proceeded to show how the first 32 moves might be determined so that, if the half of the board containing the corresponding moves from 33 to 64 was twisted through two right angles, the two routes would become united and re-entrant. If x and y are the numbers of a cell reckoned from two consecutive sides of the board, we may call the cell whose distances are respectively x and y from the opposite sides a complementary cell. Thus the cells (x, y) and (9 − x, 9 − y) are complementary, where x and y denote respectively the column and row occupied by the cell. Then in Euler's solution the numbers in complementary cells differ by 32: for instance, the cell (3, 7) is complementary to the cell (6, 2), the one is occupied by 57, the other by 25. Roget's method, which is described later, can be also applied to give half-board solutions. The result is indicated on this page. The close of Euler's memoir is devoted to showing how the method could be applied to crosses and other rectangular figures. I may note in particular his elegant re-entrant symmetrical solution for a square of 100 cells. CH. VI] KNIGHT'S PATH ON A CHESS-BOARD. 163 The next attempt of any special interest is due to Vandermonde* , who reduced the problem to arithmetic. His idea was to cover the board by two or more independent routes taken at random, and then to connect the routes. He defined the position of a cell by a fraction x/y, whose numerator x is the number of the cell from one side of the board, and whose denominator y is its number from the adjacent side of the board; this is equivalent to saying that x and y are the co-ordinates of a cell. In a series of fractions denoting a knight's path, the differences between the numerators of two consecutive fractions can be only one or two, while the corresponding difference between their denominators must be two or one respectively. Also x and y cannot be less than 1 or greater than 8. The notation is convenient, but Vandermonde applied it merely to obtain a particular solution of the problem for a board of 64 cells: the

method by which he effected this is analogous to that established by Euler, but it is applicable only to squares of an even order. The route that he arrives at is defined in his notation by the following fractions. 5 5 , 4 3 , 2 4 , 4 5 , 5 3 , 7 4 , 8 2 , 6 1 , 7 3 , 8 1 , 6 2 , 8 3 , 7 1 , 5 2 , 6 4 , 8 5 , 7 7 , 5 8 , 6 6 , 5 4 , 4 6 , 2 5 , 1 7 , 3 8 , 2 6 , 1 8 , 3 7 , 1 6 , 2 8 , 4 7 , 3 5 , 1 4 , 2 2 , 4 1 , 3 3 , 1 2 , 3 1 , 2 3 , 1 1 , 3 2 , 1 3 , 2 1 , 4 2 , 3 4 , 1 5 , 2 7 , 4 8 , 3 6 , 4 4 , 5 6 , 7 5 , 8 7 , 6 8 , 7 6 , 8 8 , 6 7 , 8 6 , 7 8 , 5 7 , 6 5 , 8 4 , 7 2 , 5 1 , 6 3 . The path is re-entrant but unsymmetrical. Had he transferred the first three fractions to the end of this series he would have obtained two symmetrical circuits of thirty-two moves joined unsymmetrically, and might have been enabled to advance further in the problem. Vandermonde also considered the case of a route in a cube. In 1773 Collini† proposed the exclusive use of symmetrical routes arranged without reference to the initial cell, but connected in such a manner as to permit of our starting from it. This is the foundation of the modern manner of attacking the problem. The method was reinvented in 1825 by Pratt‡ , and in 1840 by Roget, and has been subsequently employed by various writers. Neither Collini nor Pratt showed skill in using this method. The rule given by Roget is described later. One of the most ingenious of the solutions of the knight's path is * L'Histoire de l'Académie des Sciences for 1771, Paris, 1774, pp. 566-574. † Solution du Problème du Cavalier au Jeu des échecs, Mannheim, 1773. ‡ Studies of Chess, sixth edition, London, 1825. 164 UNICURSAL PROBLEMS. [CH. VI that given in 1823 by Warnsdorff* . His rule is that the knight must be moved always to one of the cells from which it will command the fewest squares not already traversed. The solution is not symmetrical and not re-entrant; moreover it is difficult to trace practically. The rule has not been proved to be true, but no exception to it is known: apparently it applies also to all rectangular boards which can be covered completely by a knight. It is somewhat curious that in most cases a single false step, except in the last three or four moves, will not affect the result. Warnsdorff added that when, by the rule, two or more cells are open to the knight, it may be moved to either or any of them indifferently. This is not so, and with great ingenuity two or three cases of failure have been constructed, but it would require exceptionally bad luck to happen accidentally on such a route. The above methods have been applied to boards of various shapes, especially to boards in the form of rectangles, crosses, and circles† . All the more recent investigations impose additional restrictions: such as to require that the route shall be re-entrant, or more generally that it shall begin and terminate on given cells. The best complete solution with which I am acquainted—and one which I believe is not generally known—is due to Roget‡ . It divides the whole route into four circuits, which can be combined so as to enable us to begin on any cell and terminate on any other cell of a different colour. Hence, if we like to select this last cell at a knight's move from the initial cell, we obtain a re-entrant route. On the other hand, the rule is applicable only to square boards

containing (4n) 2 cells: for example, it could not be used on the board of the French jeu des dames, which contains 100 cells. Roget began by dividing the board of 64 cells into four quarters. Each quarter contains 16 cells, and these 16 cells can be arranged in 4 groups, each group consisting of 4 cells which form a closed knight's path. All the cells in each such path are denoted by the same letter l, e, a, or p, as the case nay be. The path of 4 cells indicated by the * Des Rösselsprunges einfachste und allgemeinste Lösung, Schmalkalden, 1823: see Jaenisch, vol. ii, pp. 56–61, 273–289. † See ex. gr. T. Ciccolini's work Del Cavallo degli Scacchi, Paris, 1836. ‡ Philosophical Magazine, April, 1840, series 3, vol. xvi, pp. 305–309; see also the Quarterly Journal of Mathematics for 1877, vol. xiv, pp. 354–359. Some solutions, founded on Roget's method, are given in the Leisure Hour, Sept. 13, 1873, pp. 587–590; see also Ibid., Dec. 20, 1873, pp. 813–815. CH. VI] KNIGHT'S PATH ON A CHESS-BOARD. 165 consonants l and the path indicated by the consonants p are diamondshaped: the paths indicated respectively by the vowels e and a are square-shaped, as may be seen by looking at one of the four quarters in figure i below. l e a p l e a p a p l e a p l e e l p a e l p a p a e l p a e l l e a p l e a p a p l e a p l e e l p a e l p a p a e l p a e l Roget's Solution (i). 34 51 32 15 38 53 18 3 31 14 35 52 17 2 39 54 50 33 16 29 56 37 4 19 13 30 49 36 1 20 55 40 48 63 28 9 44 57 22 5 27 12 45 64 21 8 41 58 62 47 10 25 60 43 6 23 11 26 61 46 7 24 59 42 Roget's Solution (ii). Now all the 16 cells on a complete chess-board which are marked with the same letter can be combined into one circuit, and wherever the circuit begins we can make it end on any other cell in the circuit, provided it is of a different colour to the initial cell. If it is indifferent on what cell the circuit terminates we may make the circuit re-entrant, and in this case we can make the direction of motion round each group (of 4 cells) the same. For example, all the cells marked p can be arranged in the circuit indicated by the successive numbers 1 to 16 in figure ii above. Similarly all the cells marked a can be combined into the circuit indicated by the numbers 17 to 23; all the l cells into the circuit 33 to 48; and all the e cells into the circuit 49 to 64. Each of the circuits indicated above is symmetrical and re-entrant. The consonant and the vowel circuits are said to be of opposite kinds. The general problem will be solved if we can combine the four circuits into a route which will start from any given cell, and terminate on the 64th move on any other given cell of a different colour. To effect this Roget gave the two following rules. First. If the initial cell and the final cell are denoted the one by a consonant and the other by a vowel, take alternately circuits indicated by consonants and vowels, beginning with the circuit of 16 cells indicated by the letter of the initial cell and concluding with the circuit indicated by the letter of the final cell. 166 UNICURSAL PROBLEMS. [CH. VI Second. If the initial cell and the final cell are denoted both by consonants or both by vowels, first select a cell, Y , in the same circuit as the final cell, Z, and one move from it, next select a cell, X, belonging to one of the opposite circuits and one move from Y . This is

always possible. Then, leaving out the cells Z and Y , it always will be possible, by the rule already given, to travel from the initial cell to the cell X in 62 moves, and thence to move to the final cell on the 64th move. In both cases however it must be noticed that the cells in each of the first three circuits will have to be taken in such an order that the circuit does not terminate on a corner, and it may be desirable also that it should not terminate on any of the border cells. This will necessitate some caution. As far as is consistent with these restrictions it is convenient to make these circuits re-entrant, and to take them and every group in them in the same direction of rotation. As an example, suppose that we are to begin on the cell numbered 1 in figure ii on the previous page, which is one of those in a p circuit, and to terminate on the cell numbered 64, which is one of those in an e circuit. This falls under the first rule: hence first we take the 16 cells marked p, next the 16 cells marked a, then the 16 cells marked l, and lastly the 16 cells marked e. One way of effecting this is shown in the diagram. Since the cell 64 is a knight's move from the initial cell the route is re-entrant. Also each of the four circuits in the diagram is symmetrical, re-entrant, and taken in the same direction, and the only point where there is any apparent breach in the uniformity of the movement is in the passage from the cell numbered 32 to that numbered 33. A rule for re-entrant routes, similar to that of Roget, has been given by various subsequent writers, especially by De Polignac* and by Laquière† , who have stated it at much greater length. Neither of these authors seems to have been aware of Roget's theorems. De Polignac, like Roget, illustrates the rule by assigning letters to the various squares in the way explained above, and asserts that a similar rule is applicable to all even squares. Roget's method can be also applied to two half-boards, as indicated * Comptes Rendus, April, 1861; and Bulletin de la Société Mathématique de France, 1881, vol. ix, pp. 17–24. † Bulletin de la Société Mathématique de France, 1880, vol. viii, pp. 82–102, 132– 158. CH. VI] KNIGHT'S PATH ON A CHESS-BOARD. 167 in the figure given above on page 162. Another way of dividing the board into closed circuits which can be connected was given in 1843 by Moon* . He divided the board into a a b c d a b c d c d a b c d a b b a A B C D d c d c C D A B b a a b B A D C c d c d D C B A a b b a d c b a d c d c b a d c b a Moon's Solution. 63 22 15 40 1 42 59 18 14 39 64 21 60 17 2 43 37 62 23 16 41 4 19 58 24 13 38 61 20 57 44 3 11 36 25 52 29 46 5 56 26 51 12 33 8 55 30 45 35 10 49 28 53 32 47 6 50 27 34 9 48 7 54 31 Jaenisch's Solution. central square containing 4 2 cells and a surrounding annulus (see figure on this page). The annulus may be divided into four closed circuits, each containing 12 cells: these are marked respectively with the letters a, b, c, d. The central square may be divided similarly into four closed circuits, each containing 4 cells, denoted by the letters A, B, C, D. We can connect these routes as follows. If we are moving outwards from the central square to the annulus we can go from a cell A either to b or to c or to d (but not to a) and similarly for the other letters. If we

are moving inwards from the annulus to the central square we must go from a to D, or d to A, or b to C, or c to B, as the case may be. Thus if the initial cell is on a, we might take either of the cycles a D b C d A c B, or a D c B d A b C. By following these rules we always can connect the routes into one path, but in general it will not be re-entrant. It is convenient to take the cells in each circuit in one and the same direction, but a circuit in the outer annulus must not end in a corner cell, and to avoid this we may have to alter the direction in which a circuit is taken. Moon's rule can be modified to cover the case of any doubly even square board, and the path can be made to begin and end on any two given squares, but I do not propose to go further into details. * Cambridge Mathematical Journal, 1843, vol. iii, pp. 233–236. 168 UNICURSAL PROBLEMS. [CH. VI The method which Jaenisch gives as the most fundamental is not very different from that of Roget. It leads to eight forms, similar to that in the diagram printed on the previous page, in which the sum of the numbers in every column and every row is 260; but although symmetrical it is not in my opinion so easy to reproduce as that given by Roget. It is as yet impossible to say how many solutions of the problem exist. Legendre* mentioned the question, but Minding† was the earliest writer to attempt to answer it. More recent investigations have shown that on the one hand the number of possible routes is less‡ than the number of combinations of 168 things taken 63 at a time, and on the other hand is greater than 31, 054144—since this latter number is the number of re-entrant paths of a particular type§ . There are many similar problems in which it is required to determine routes by which a piece moving according to certain laws (ex. gr. a chess-piece such as a king, knight, &c.) can travel from a given cell over a board so as to occupy successively all the cells, or certain specified cells, once and only once, and terminate its route in a given cell. Euler's method can be applied to find routes of this kind: for instance, he applied it to find a re-entrant route by which a piece that moved two cells forward like a castle and then one cell like a bishop would occupy in succession all the black cells on the board. As another instance, a castle, placed on a chess-board of n 2 cells, can always be moved in such a manner that it shall move successively on to every cell once and only once; moreover, starting on any cell, its path can be made to terminate, if n be even, on any other cell of a different colour, and, if n be odd, on any other cell of the same colour‖ . But it will suffice to have discussed the classical problem of the determination of a knight's path on an ordinary chess-board, and I need not enter on the discussion of other similar problems. * Théorie des Nombres, Paris, 2nd edition, 1830, vol. ii, p. 165. † Cambridge and Dublin Mathematical Journal, 1852, vol. vii, pp. 147–156; and Crelle's Journal, 1853, vol. xliv, pp. 73–82. ‡ Jaenisch, vol. ii, p. 268. § Bulletin de la Société Mathématique de France, 1881, vol. ix, pp. 1–17. ‖ L'Intermédiaire des mathématiciens, Paris, July, 1901, p. 153. PART II. Miscellaneous Essays and Problems. "No man of science should think it a waste of time to learn something of the history of his

own subject; nor is the investigation of laborious methods now fallen into disuse, or of errors once commonly accepted the least valuable of mental disciplines." "The most worthless book of a bygone day is a record worthy of preservation. Like a telescopic star, its obscurity may render it unavailable for most purposes; but it serves, in hands which know how to use it, to determine the places of more important bodies." (De Morgan.) 169 CHAPTER VII. THE MATHEMATICAL TRIPOS. The Mathematical Tripos has played so prominent a part in the history of education at Cambridge and of mathematics in England, that a sketch of its development† may be interesting to general readers. So far as mathematics is concerned the history of the University before Newton may be summed up very briefly. The University was founded towards the end of the twelfth century. Throughout the middle ages the studies were organised on lines similar to those at Paris and Oxford. To qualify for a degree it was necessary to perform various exercises, and especially to keep a number of acts or to oppose acts kept by other students. An act consisted in effect of a debate in Latin, thrown, at any rate in later times, into syllogistic form. It was commenced by one student, the respondent, stating some proposition, often propounded in the form of a thesis, which was attacked by one or more opponents, the discussion being controlled by a graduate. The teaching was largely in the hands of young graduates—every master of arts being compelled to reside and teach for at least one year—though no doubt Colleges and private hostels supplemented this instruction in the case of their own students. † The following pages are mostly summarised from my History of the Study of Mathematics at Cambridge, Cambridge 1889. The subject is also treated in Whewell's Liberal Education, Cambridge, three parts, 1845, 1850, 1853; Wordsworth's Scholae Academicae, Cambridge, 1877; my own Origin and History of the Mathematical Tripos, Cambridge, 1880; and Dr Glaisher's Presidential Address to the London Mathematical Society, Transactions, vol xviii, 1886, pp. 4–38. 170 CH. VII] THE MATHEMATICAL TRIPOS. 171 The Reformation in England was mainly the work of Cambridge divines, and in the University the Renaissance was warmly welcomed. In spite of the disorder and confusion of the Tudor period, new studies and a system of professional instruction were introduced. Probably the science (as distinct from the art) of mathematics, save so far as involved in the quadrivium, was still an exotic study, but it was not wholly neglected. Tonstall, subsequently the most eminent English arithmetician of his time, migrated, perhaps about 1495, from Balliol College, Oxford, to King's Hall, Cambridge, and in 1530 the University appointed a mathematical lecturer in the person of Paynell of Pembroke Hall. Most of the subsequent English mathematicians of the Tudor period seem to have been educated at Cambridge; of these I may mention Record, who migrated, probably about 1535, from Oxford, Dee, Digges, Blundeville, Buckley, Billingsley, Hill, Bedwell, Hood, Richard and John Harvey, Edward Wright, Briggs, and Oughtred. The Elizabethan

statutes restricted liberty of thought and action in many ways, but, in spite of the civil and religious disturbances of the early half of the 17th century the mathematical school continued to grow. Horrox, Seth Ward, Foster, Rooke, Gilbert Clerke, Pell, Wallis, Barrow, Dacres, and Morland may be cited as prominent Cambridge mathematicians of the time. Newton's mathematical career dates from 1665; his reputation, abilities, and influence attracted general attention to the subject. He created a school of mathematics and mathematical physics, among the earliest members of which I note the names of Laughton, Samuel Clarke, Craig, Flamsteed, Whiston, Saunderson, Jurin, Taylor, Cotes, and Robert Smith. Since then Cambridge has been regarded, as in a special sense, the home of English mathematicians, and from 1706 onwards we have fairly complete accounts of the course of reading and work of mathematical students there. Until less than a century ago the form of the method of qualifying for a degree remained substantially unaltered, but the subject-matter of the discussions varied from time to time with the prevalent studies of the place. After the Renaissance some of the statutable exercises were "huddled," that is, were reduced to a mere form. To huddle an act, the proctor generally asked some question such as Quid est nomen to which the answer usually expected was Nescio. In these exercises considerable license was allowed, particularly if there were any play on the words 172 THE MATHEMATICAL TRIPOS. [CH. VII involved. For example, T. Brasse, of Trinity, was accosted with the question, Quid est aes? to which he answered, Nescio nisi finis examinationis. It should be added that retorts such as these were only allowed in the pretence exercises, and a candidate who in the actual examination was asked to give a definition of happiness and replied an exemption from Payne—that being the name of the moderator then presiding—was plucked for want of discrimination in time and place. In earlier years even the farce of huddling seems to have been unnecessary, for it was said in 1675 that it was not uncommon for the proctors to take "cautions for the performance of the statutable exercises, and accept the forfeit of the money so deposited in lieu of their performance." In medieval times acts had been usually kept on some scholastic question or on a proposition taken from the Sentences. About the end of the fifteenth century religious questions, such as the interpretation of Biblical texts, began to be introduced, some fifty or sixty years later the favourite subjects were drawn either from dogmatic theology or from philosophy. In the seventeenth century the questions were usually philosophical, but in the eighteenth century, under the influence of the Newtonian school, a large proportion of them were mathematical. Further details about these exercises and specimens of acts kept in the 18th century are given in my History of Mathematics at Cambridge. Here I will only say that they provided an admirable training in the art of presenting an argument, and in dialectical skill in attack and defence. The mental strain in a contested act was severe. De Morgan, describing his act kept

in 1826, wrote* , I was badgered for two hours with arguments given and answered in Latin,—or what we call Latin—against Newton's first section, Lagrange's derived functions, and Locke on innate principles. And though I took off everything, and was pronounced by the moderator to have disputed magno honore, I never had such a strain of thought in my life. For the inferior opponents were made as sharp as their betters by their tutors, who kept lists of queer objections drawn from all quarters. Had the language of the discussions been changed to English, as was repeatedly urged from 1774 onwards, these exercises might have been retained with advantage, but the barbarous Latin and the syllogistic form in which they were carried on prejudiced their retention. About 1830 a custom grew up for the respondent and opponents to meet previously and arrange their arguments together. The discussions * Budget of Paradoxes, by A. De Morgan, London, 1872, p. 305. CH. VII] THE MATHEMATICAL TRIPOS. 173 then became an elaborate farce, and were a mere public performance of what had been already rehearsed. Accordingly the moderators of 1839 took the responsibility of abandoning them. This action was singularly high-handed, since a report of May 30, 1838, had recommended that they should be continued, and there was no reason why they should not have been reformed and retained as a useful feature in the scheme of study. On the result of the acts a list of those qualified to receive degrees was drawn up. This list was not arranged strictly in order of merit, because the proctors could insert names anywhere in it, but by the beginning of the 18th century this power had become restricted to the right reserved to the vice-chancellor, the senior regent, and each proctor to place in the list one candidate anywhere he liked—a right which continued to exist till 1828, though it was not exercised after 1797. Subject to the granting of these honorary degrees, this final list was arranged in order of merit into wranglers and senior optimes, junior optimes, and poll-men. The bachelors on receiving their degrees took seniority according to their order on this list. The title wrangler is derived from these contentious discussions; the title optime from the customary compliment given by the moderator to a successful disputant, Domine. . . , optime disputasti, or even optime quidem disputasti, and the title of poll-man from the description of this class as oÉ πολλοÐ. The final exercises for the B.A. degree were never huddled, and until 1839 were carried out strictly. University officials were responsible for approving the subject-matter of these acts. Stupid men offered some irrefutable truism, but the ambitious student courted reputation by affirming some paradox. Probably all honour men kept acts, but poll-men were deemed to comply with the regulations by keeping opponencies. The proctors were responsible for presiding at these acts, or seeing that competent graduates did so. In and after 1649 two examiners were specially appointed for this purpose. In 1680* these examiners were appointed by the Senate with the title of moderator, and with the joint stipend of four shillings for everyone graduating as B.A. during

their year of office. In 1688 the joint stipend of the moderators was fixed at £40 a year. The moderators, like the proctors, were nominated by the Colleges in rotation. From the earliest times the proctors had the power of questioning * See Grace of October 25, 1680. 174 THE MATHEMATICAL TRIPOS. [CH. VII a candidate at the end of a disputation, and probably all candidates for a degree attended the public schools on certain days to give an opportunity to the proctors, or any master that liked, to examine them* , though the opportunity was not always used. Different candidates attended on different days. Probably such examinations were conducted in Latin. But soon after 1710† the moderators or proctors began the custom of summoning on one day in January all candidates whom they proposed to question. The examination was held in public, and from it the Senate-House Examination arose. The examination at this time did not last more than one day, and was, there can be no doubt, partly on philosophy and partly on mathematics. It is believed that it was always conducted in English, and it is likely that its rapid development was largely due to this. This introduction of a regular oral examination seems to have been largely due to the fact that when, in 1710, George I gave the Ely library to the University, it was decided to assign for its reception the old Senate-House—now the Catalogue Room in the Library—and to build a new room for the meetings of the Senate. Pending the building of the new Senate-House the books were stored in the Schools. As the Schools were thus rendered unavailable for keeping acts, considerable difficulty was found in arranging for all the candidates to keep the full number of statutable exercises, and thus obtaining opportunities to compare them one with another: hence the introduction of a supplementary oral examination. The advantages of this examination as providing a ready means of testing the knowledge and abilities of the candidates were so patent that it was retained when the necessity for some system of the kind had passed away, and finally it became systematized into an organized test to which all questionists were subjected. In 1731 the University raised the joint stipend of the moderators to £60 “in consideration of their additional trouble in the Lent Term.” This would seem to indicate that the Senate-House Examination had then taken formal shape, and perhaps that a definite scheme for its conduct had become customary. * Ex. gr. see De la Pryme’s account of his graduation in 1694, Surtees Society, vol. liv, 1870, p. 32. † W. Reneu, in his letters of 1708–1710 describing the course for the B.A. degree, makes no mention of the Senate-House examination, and I think it is a reasonable inference that it had not then been established. CH. VII] THE MATHEMATICAL TRIPOS. 175 As long as the order of the list of those approved for degrees was settled on the result of impressions derived from acts kept by the different candidates at different times and on different subjects, it was impossible to arrange the men in strict order of merit, nor was much importance attached to the order. But, with the introduction of an examination of all the candidates on one day,

much closer attention was paid to securing a strict order of merit, and more confidence was felt in the published order. It seems to have been consequent on this that in and after 1747 the final lists were freely circulated, and it was further arranged that the names of the honorary optimes should be indicated. In the lists given in the Calendars issued subsequent to 1799 these names are struck out. It is only in exceptional cases that we are acquainted with the true order for the earlier tripos lists, but in a few cases the relative positions of the candidates are known; for example, in 1680 Bentley came out as third though he was put down as sixth in the list of wranglers. Of the detailed history of the examination until the middle of the eighteenth century we know nothing. From 1750 onwards, however, we have more definite accounts of it. At this time, it would seem that all the men from each College were taken together as a class, and questions passed down by the proctors or moderators till they were answered: but the examination remained entirely oral, and technically was regarded as subsidiary to the discussions which had been previously held in the schools. As each class contained men of very different abilities a custom grew up by which every candidate was liable to be taken aside to be questioned by any M.A. who wished to do so, and this was regarded as an important part of the examination. The subjects were mathematics and philosophy. The examination now continued for two days and a half. At the conclusion of the second day the moderators received the reports of those masters of arts who had voluntarily taken part in the examination, and provisionally settled the final list; while the last halfday was used in revising and re-arranging the order of merit. Richard Cumberland has left an account of the tests to which he was subjected when he took his B.A. degree in 1751. Clearly the disputations still played an important part, and it is difficult to say what weight was attached to the subsequent Senate-House examination; his reference to it is only of a general character. After saying that he kept 176 THE MATHEMATICAL TRIPOS. [CH. VII two acts and two opponencies he continues* : The last time I was called upon to keep an act in the schools I sent in three questions to the Moderator, which he withstood as being all mathematical, and required me to conform to the usage of proposing one metaphysical question in the place of that, which I should think fit to withdraw. This was ground I never liked to take, and I appealed against his requisition: the act was accordingly put by till the matter of right should be ascertained by the statutes of the university, and in the result of that enquiry it was given for me, and my question stood. . . . I yielded now to advice, and paid attention to my health, till we were cited to the senate house to be examined for our Bachelor's degree. It was hardly ever my lot during that examination to enjoy any respite. I seemed an object singled out as every man's mark, and was kept perpetually at the table under the process of question and answer. It was found possible by means of the new examination to differentiate the better men more accurately than before; and accordingly, in

1753, the first class was subdivided into two, called respectively wranglers and senior optimes, a division which is still maintained. The semi-official examination by M.A.s was regarded as the more important part of the test, and the most eminent residents in the University took part in it. Thus John Fenn, of Caius, 5th wrangler in 1761, writes† : On the following Monday, Tuesday, and Wednesday, we sat in the Senate-house for public examination; during this time I was officially examined by the Proctors and Moderators, and had the honor of being taken out for examination by Mr Abbot, the celebrated mathematical tutor of St John's College, by the eminent professor of mathematics Mr Waring, of Magdalene, and by Mr Jebb of Peterhouse, a man thoroughly versed in the academical studies. This irregular examination by any master who chose to take part in it constantly gave rise to accusations of partiality. In 1763 the traditional rules for the conduct of the examination took more definite shape. Henceforth the examiners used the disputations only as a means of classifying the men roughly. On the result of their "acts," and probably partly also of their general reputation, the candidates were divided into eight classes, each arranged in alphabetical order. The subsequent position of the men in the class was determined solely by the Senate-House examination. The first two classes * Memoirs of Richard Cumberland, London, 1806, pp. 78, 79. † Quoted by C. Wordsworth, Scholae Academicae, Cambridge, 1877, pp. 30–31. CH. VII] THE MATHEMATICAL TRIPOS. 177 comprised all who were expected to be wranglers, the next four classes included the other candidates for honours, and the last two classes consisted of poll-men only. Practically anyone placed in either of the first two classes was allowed, if he wished, to take an aegrotat senior optime, and thus escape all further examination: this was called gulphing it. All the men from one College were no longer taken together, but each class was examined separately and vivâ voce; and hence, since all the students comprised in each class were of about equal attainments, it was possible to make the examination more effective. Richard Watson, of Trinity, claimed that this change was made by him when acting as moderator in 1763. He says* : There was more room for partiality. . . then [i.e. in 1759] than there is now; and I attribute the change, in a great degree, to an alteration which I introduced the first year I was moderator [i.e. in 1763], and which has been persevered in ever since. At the time of taking their Bachelor of Arts' degree, the young men are examined in classes, and the classes are now formed according to the abilities shown by individuals in the schools. By this arrangement, persons of nearly equal merits are examined in the presence of each other, and flagrant acts of partiality cannot take place. Before I made this alteration, they were examined in classes, but the classes consisted of members of the same College, and the best and worst were often examined together. It is probable that before the examination in the Senate-House began a candidate, if manifestly placed in too low a class, was allowed the privilege of challenging the class to

which he was assigned. Perhaps this began as a matter of favour, and was only granted in exceptional cases, but a few years later it became a right which every candidate could exercise; and I think that it is partly to its development that the ultimate predominance of the tripos over the other exercises for the degree is due. In the same year, 1763, it was decided that the relative position of the senior and second wranglers, namely, Paley, of Christ's, and Frere, of Caius, was to be decided by the Senate-House examination and not by the disputations. Henceforward distinction in the SenateHouse examination was regarded as the most important honour open to undergraduates. In 1768 Dr Smith, of Trinity College, founded prizes for mathematics and natural philosophy open to two commencing bachelors. The * Anecdotes of the Life of Richard Watson by Himself, London, 1817, pp. 18, 19. 178 THE MATHEMATICAL TRIPOS. [CH. VII examination followed immediately after the Senate-House examination, and the distinction, being much coveted, tended to emphasize the mathematical side of the normal University education of the best men. Since 1883 the prizes have been awarded on the result of dissertations* . Until now the Senate-House examination had been oral, but about this time, circ. 1770, it began to be the custom to dictate some or all of the questions and to require answers to be written. Only one question was dictated at a time, and a fresh one was not given out until some student had solved that previously read: a custom which by causing perpetual interruptions to take down new questions must have proved very harassing. We are perhaps apt to think that an examination conducted by written papers is so natural that the custom is of long continuance, but I know no record of any in Europe earlier than the eighteenth century. Until 1830 the questions for the Smith's Prize were dictated. The following description of the Senate-House examination as it existed in 1772 is given by Jebb† . The moderators, some days before the arrival of the time prescribed by the vice-chancellor, meet for the purpose of forming the students into divisions of six, eight, or ten, according to their performance in the schools, with a view to the ensuing examination. Upon the first of the appointed days, at eight o'clock in the morning, the students enter the senate-house, preceded by a master of arts from each college, who. . . is called the "father" of the college. . . After the proctors have called over the names, each of the moderators sends for a division of the students: they sit with him round a table, with pens, ink, and paper, before them: he enters upon his task of examination, and does not dismiss the set till the hour is expired. This examination has now for some years been held in the english language. The examination is varied according to the abilities of the students. The moderator generally begins with proposing some questions from the six books of Euclid, plain trigonometry, and the first rules of algebra. If any person fails in an answer, the question goes to the next. From the elements of mathematics, a transition is made to the four branches of philosophy, viz. mechanics, hydrostatics, apparent astronomy, and optics,

as explained in the works of Maclaurin, Cotes, Helsham, Hamilton, Rutherforth, Keill, Long, Ferguson, and Smith. If the moderator finds the set of questionists, under examination, capable of answering * See Grace of October 25, 1885; and the Cambridge University Reporter, October 23 and 30, 1883. † The Works of J. Jebb, London, 1787, vol. ii, pp. 290–297. CH. VII] THE MATHEMATICAL TRIPOS. 179 him, he proceeds to the eleventh and twelfth books of Euclid, conic sections, spherical trigonometry, the higher parts of algebra, and sir Isaac Newton's Principia; more particularly those sections, which treat of the motion of bodies in eccentric and revolving orbits; the mutual action of spheres, composed of particles attracting each other according to various laws; the theory of pulses, propagated through elastic mediums; and the stupendous fabric of the world. Having closed the philosophical examination, he sometimes asks a few questions in Locke's Essay on the human understanding, Butler's Analogy, or Clarke's Attributes. But as the highest academical distinctions are invariably given to the best proficients in mathematics and natural philosophy, a very superficial knowledge in morality and metaphysics will suffice. When the division under examination is one of the highest classes, problems are also proposed, with which the student retires to a distant part of the senate-house; and returns, with his solution upon paper, to the moderator, who, at his leisure, compares it with the solutions of other students, to whom the same problems have been proposed. The extraction of roots, the arithmetic of surds, the invention of divisers, the resolution of quadratic, cubic, and biquadratic equations; together with the doctrine of fluxions, and its application to the solution of questions "de maximis et minimis," to the finding of areas, to the rectification of curves, the investigation of the centers of gravity and oscillation, and to the circumstances of bodies, agitated, according to various laws, by centripetal forces, as unfolded, and exemplified, in the fluxional treatises of Lyons, Saunderson, Simpson, Emerson, Maclaurin, and Newton, generally form the subject matter of these problems. When the clock strikes nine, the questionists are dismissed to breakfast: they return at half past nine, and stay till eleven; they go in again at half past one, and stay till three; and, lastly, they return at half-past three, and stay till five. The hours of attendance are the same upon the subsequent day. On the third day they are finally dismissed at eleven. During the hours of attendance, every division is twice examined in form, once by each of the moderators, who are engaged for the whole time in this employment. As the questionists are examined in divisions of only six or eight at a time, but a small portion of the whole number is engaged, at any particular hour, with the moderators; and, therefore, if there were no further examination, much time would remain unemployed. But the moderator's inquiry into the merits of the candidates forms the least material part of the examination. The "fathers" of the respective colleges, zealous for the credit of the societies, of which they are the guardians, are incessantly employed in examining those students,

who appear most likely to contest the palm of glory with their sons. This part of the process is as follows: 180 THE MATHEMATICAL TRIPOS. [CH. VII The father of a college takes a student of a different college aside, and, sometimes for an hour and an half together, strictly examines him in every part of mathematics and philosophy, which he professes to have read. After he hath, from this examination, formed an accurate idea of the student's abilities and acquired knowledge, he makes a report of his absolute or comparative merit to the moderators, and to every other father who shall ask him the question. Besides the fathers, all masters of arts, and doctors, of whatever faculty they be, have the liberty of examining whom they please; and they also report the event of each trial, to every person who shall make the inquiry. The moderators and fathers meet at breakfast, and at dinner. From the variety of reports, taken in connection with their own examination, the former are enabled, about the close of the second day, so far to settle the comparative merits of the candidates, as to agree upon the names of fourand-twenty, who to them appear most deserving of being distinguished by marks of academical approbation. These four-and-twenty [wranglers and senior optimes] are recommended to the proctors for their private examination; and, if approved by them, and no reason appears against such placing of them from any subsequent inquiry, their names are set down in two divisions, according to that order, in which they deserve to stand; are afterwards printed; and read over upon a solemn day, in the presence of the vice-chancellor, and of the assembled university. The names of the twelve [junior optimes], who, in the course of the examination, appear next in desert, are also printed, and are read over, in the presence of the vice-chancellor, and of the assembled university, upon a day subsequent to the former. . . The students, who appear to have merited neither praise nor censure, [the poll-men], pass unnoticed: while those, who have taken no pains to prepare themselves for the examination, and have appeared with discredit in the schools, are distinguished by particular tokens of disgrace. Jebb's statement about the number of wranglers and senior optimes is only approximate. It may be added that it was now frankly recognized that the examination was competitive* . Also that though it was open to any member of the Senate to take part in it, yet the determination of the relative merit of the students was entirely in the hands of the moderators† . Although the examination did not occupy more than three days it must have been a severe physical trial to anyone who was delicate. It was held in winter and in the Senate-House. That building was then noted * "Emulation, which is the principle upon which the plan is constructed." The Works of J. Jebb, London, 1787, vol. iii, p. 261. † The Works of J. Jebb, London, 1787, vol. iii, p. 272. CH. VII] THE MATHEMATICAL TRIPOS. 181 for its draughts, and was not warmed in any way: and according to tradition, on one occasion the candidates on entering in the morning found the ink in the pots on their desks frozen. The University was not altogether satisfied*

with the scheme in force, and in 1779† the scheme of examination was amended in various respects. In particular the examination was extended to four days, a third day being given up entirely to natural religion, moral philosophy, and Locke. It was further announced‡ that a candidate would not receive credit for advanced subjects unless he had satisfied the examiners in Euclid and elementary Natural Philosophy. A system of brackets or “classes quam minimae” was now introduced. Under this system the examiners issued on the morning of the fourth day a provisional list of men who had obtained honours, with the names of those of about equal merit bracketed, and that day was devoted to arranging the names in each bracket in order of merit: the examiners being given explicit authority to invite the assistance of others in this work. Whether at this time a candidate could request to be re-examined with the view of being moved from one bracket to another is uncertain, but later this also was allowed. Under the scheme of 1779 also the number of examiners was increased to four, the moderators of one year becoming, as a matter of course, the examiners of the next. Thus of the four examiners in each year, two had taken part in the examination of the previous year, and the continuity of the system of examination was maintained. The names of the moderators appear on the tripos lists, but the names of the examiners were not printed on the lists till some years later. The right of any M.A. to take part in the examination was not affected, though henceforth it was exercised more sparingly, and I believe was not insisted on after 1785. But it became a regular custom for the moderators to invite particular M.A.s to examine and compare specified candidates. Milner, of Queens’, was constantly asked to assist in this way. It was not long before it became an established custom that a candidate, who was dissatisfied with the class in which he had been placed as the result of his disputations, might challenge it before the * See Graces of July 5, 1773, and of February 17, 1774. † See Graces of March 19, 20, 1779. ‡ Notice issued by the Vice-Chancellor, dated May 19, 1779. 182 THE MATHEMATICAL TRIPOS. [CH. VII examination began. This power seems to have been used but rarely; it was, however, a recognition of the fact that a place in the tripos list was to be determined by the Senate-House examination alone, and the examiners soon acquired the habit of settling the preliminary classes without exclusive reference to the previous disputations. The earliest papers actually set in the Senate-House, and now extant, are two problem papers set in 1785 and 1786 by W. Hodson, of Trinity, then a proctor. The autograph copies from which he gave out the questions were luckily preserved, and are in the library* of Trinity College. They must be almost the last problem papers which were dictated, instead of being printed and given as a whole to the candidates. The problem paper in 1786 was as follows: 1. To determine the velocity with which a Body must be thrown, in a direction parallel to the Horizon, so as to become a secondary planet to the Earth; as also to describe a parabola, and never return. 2. To demonstrate, supposing the force to

vary as 1 D2 , how far a body must fall both within and without the Circle to acquire the Velocity with which a body revolves in a Circle. 3. Suppose a body to be turned (sic) upwards with the Velocity with which it revolves in an Ellipse, how high will it ascend? The same is asked supposing it to move in a parabola. 4. Suppose a force varying first as 1 D3 , secondly in a greater ratio than 1 D2 but less than 1 D3 , and thirdly in a less ratio than 1 D2 , in each of these Cases to determine whether at all, and where the body parting from the higher Apsid will come to the lower. 5. To determine in what situation of the moon's Apsid they go most forwards, and in what situation of her Nodes the Nodes go most backwards, and why? 6. In the cubic equation x 3 + qx + r = 0 which wants the second term; supposing x = a + b and 3ab = −q, to determine the value of x. 7. To find the fluxion of x r × (y n + z m) 1/q . 8. To find the fluent of ax˙ a + x . 9. To find the fluxion of the mth power of the Logarithm of x. 10. Of right-angled Triangles containing a given Area to find that whereof the sum of the two legs AB + BC shall be the least possible. [This and the two following questions are illustrated by diagrams. The angle at B is the right angle.] 11. To find the Surface of the Cone ABC. [The cone is a right one on a circular base.] 12. To rectify the arc DB of the semicircle DBV . * The Challis Manuscripts, iii, 61. CH. VII] THE MATHEMATICAL TRIPOS. 183 In cases of equality in the Senate-House examination the acts were still taken into account in settling the tripos order: and in 1786 when the second, third, and fourth wranglers came out equal in the examination a memorandum was published that the second place was given to that candidate who dialectis magis est versatus, and the third place to that one who in scholis sophistarum melius disputavit. There seem to have been considerable intervals in the examination by the moderators, and the examinations by the extraneous examiners took place in these intervals. Those candidates who at any time were not being examined occupied themselves with amusements, provided they were not too boisterous and obvious: probably dice and cards played a large part in them. Gunning in an amusing account of his examination in 1788 talks of games with a teetotum* in which he took part on the Wednesday (when Locke and Paley formed the subjects of examination), but "which was carried on with great spirit. . . by considerable numbers during the whole of the examination." About this time, 1790, the custom of printing the problem papers was introduced, but until 1828 the other papers continued to be dictated. Since 1827 all the papers have been printed. I insert here the following letter† from William Gooch, of Caius, in which he describes his examination in the Senate-House in 1791. It must be remembered that it is the letter of an undergraduate addressed to his father and mother, and was not intended either for preservation or publication: a fact which certainly does not detract from its value. Monday 1 4 aft. 12. We have been examin'd this Morning in pure Mathematics & I've hitherto kept just about even with Peacock which is much more than I expected. We are going at 1 o'clock to be examin'd

till 3 in Philosophy. From 1 till 7 I did more than Peacock; But who did most at Moderator's Rooms this Evening from 7 till 9, I don't know yet;—but I did above three times as much as the Senr Wrangler last year, yet I'm afraid not so much as Peacock. Between One & three o'Clock I wrote up 9 sheets of Scribbling Paper so you may suppose I was pretty fully employ'd. Tuesday Night. I've been shamefully us'd by Lax to-day;—Tho' his anxiety for Peacock must (of course) be very great, I never suspected that his Partially (sic) w d get the better of his Justice. I had entertain'd too high an opinion of * H. Gunning, Reminiscences, second edition, London, 1855, vol. i, p. 82. † C. Wordsworth, Scholae Academicae, Cambridge, 1877, pp. 322–23. 184 THE MATHEMATICAL TRIPOS. [CH. VII him to suppose it.—he gave Peacock a long private Examination & then came to me (I hop'd) on the same subject, but 'twas only to Bully me as much as he could,—whatever I said (tho' right) he tried to convert into Nonsense by seeming to misunderstand me. However I don't entirely dispair of being first, tho' you see Lax seems determin'd that I shall not.—I had no Idea (before I went into the Senate-House) of being able to contend at all with Peacock. Wednesday evening. Peacock & I are still in perfect Equilibrio & the Examiners themselves can give no guess yet who is likely to be first;—a New Examiner (Wood of St. John's, who is reckon'd the first Mathematician in the University, for Waring doesn't reside) was call'd solely to examine Peacock & me only.— but by this new Plan nothing is yet determin'd.—So Wood is to examine us again to-morrow morning. Thursday evening. Peacock is declar'd first & I second,—Smith of this Coll. is either 8th or 9th & Lucas is either 10th or 11th.—Poor Quiz Carver is one of the oÉ πολλοÐ;—I'm perfectly satisfied that the Senior Wranglership is Peacock's due, but certainly not so very indisputably as Lax pleases to represent it—I understand that he asserts 'twas 5 to 4 in Peacock's favor. Now Peacock & I have explain'd to each other how we went on, & can prove indisputably that it wasn't 20 to 19 in his favor;—I cannot therefore be displeas'd for being plac'd second, tho' I'm provov'd (sic) with Lax for his false report (so much beneath the Character of a Gentleman.)— N.B. it is my very particular Request that you don't mention Lax's behaviour to me to any one. Such was the form ultimately taken by the Senate-House examination, a form which it substantially retained without alteration for nearly half-a-century. It soon became the sole test by which candidates were judged. The University was not obliged to grant a degree to anyone who performed the statutable exercises, and it was open to the University to refuse to pass a supplicat for the B.A. degree unless the candidate had presented himself for the Senate-House examination. In 1790 James Blackburn, of Trinity, a questionist of exceptional abilities, was informed that in spite of his good disputations he would not be allowed a degree unless he also satisfied the examiners in the tripos. He accordingly solved one "very hard problem," though in consequence of a dispute with the authorities he refused to attempt any more.* It

will be recollected that the examination was now compulsory on all candidates pursuing the normal course for the B.A. degree. In 1791 * Gunning, Reminiscences, second edition, London, 1855, vol. i, p. 182. CH. VII] THE MATHEMATICAL TRIPOS. 185 the University laid down rules* for its conduct, so far as it concerned poll-men, decreeing that those who passed were to be classified in four divisions or classes, the names in each class to be arranged alphabetically, but not to be printed on the official tripos lists. The classes in the final lists must be distinguished from the eight preliminary classes issued before the commencement of the examination. The men in the first six preliminary classes were expected to take honours; those in the seventh and eighth preliminary classes were primâ facie poll-men. In 1799 the moderators announced† that for the future they would require every candidate to show a competent knowledge of the first book of Euclid, arithmetic, vulgar and decimal fractions, simple and quadratic equations, and Locke and Paley. Paley's works seem to be held in esteem by modern divines, and his Evidences, though not his Philosophy, still remains (1905) one of the subjects of the Previous Examination, but his contemporaries thought less highly of his writings, or at any rate of his Philosophy. Thus Best is quoted by Wordsworth‡ as saying of Paley's Philosophy, "The tutors of Cambridge no doubt neutralize by their judicious remarks, when they read it to their pupils, all that is pernicious in its principles": so also Richard Watson, Bishop of Llandaff, in his anecdotal autobiography§ , says, in describing the Senate-House examination in which Paley was senior wrangler, that Paley was afterwards known to the world by many excellent productions, "though there are some. . . principles in his philosophy which I by no means approve." In 1800 the moderators extended to all men in the first four preliminary classes the privilege of being allowed to attempt the problem papers: hitherto this privilege had been confined to candidates placed in the first two classes. Until 1828 the problem papers were set in the evenings, and in the rooms of the moderator. The University Calendars date from 1796, and from 1802 to 1882 inclusive contain the printed tripos papers of the previous January. The papers from 1801 to 1820 and from 1838 to 1849 inclusive were also published in separate volumes, which are to be found in most public libraries. No problems were ever set to the men in the seventh and * See Grace of April 8, 1791. † Communicated by the moderators to fathers of Colleges on January 18, 1799, and agreed to by the latter. ‡ C. Wordsworth, Scholae Academicae, Cambridge, 1877, p. 123. § Anecdotes of the Life of R. Watson, London, 1817, p. 19. 186 THE MATHEMATICAL TRIPOS. [CH. VII eighth preliminary classes, which contained the poll-men. None of the bookwork papers of this time are now extant, but it is believed that they contained but few riders. Many of the so-called problems were really pieces of bookwork or easy riders: it must however be remembered that the text-books then in circulation were inferior and incomplete as compared with modern ones. The Calendar of 1802 contains a diffuse

account of the examination. It commences as follows: On the Monday morning, a little before eight o'clock, the students, generally about a hundred, enter the Senate-House, preceded by a master of arts, who on this occasion is styled the father of the College to which he belongs. On two pillars at the entrance of the Senate-House are hung the classes and a paper denoting the hours of examination of those who are thought most competent to contend for honours. Immediately after the University clock has struck eight, the names are called over, and the absentees, being marked, are subject to certain fines. The classes to be examined are called out, and proceed to their appointed tables, where they find pens, ink, and paper provided in great abundance. In this manner, with the utmost order and regularity, two-thirds of the young men are set to work within less than five minutes after the clock has struck eight. There are three chief tables, at which six examiners preside. At the first, the senior moderator of the present year and the junior moderator of the preceding year. At the second, the junior moderator of the present and the senior moderator of the preceding year. At the third, two moderators of the year previous to the two last, or two examiners appointed by the Senate. The two first tables are chiefly allotted to the six first classes; the third, or largest, to the oÉ πολλοÐ. The young men hear the propositions or questions delivered by the examiners; they instantly apply themselves; demonstrate, prove, work out and write down, fairly and legibly (otherwise their labour is of little avail) the answers required. All is silence; nothing heard save the voice of the examiners; or the gentle request of some one, who may wish a repetition of the enunciation. It requires every person to use the utmost dispatch; for as soon as ever the examiners perceive anyone to have finished his paper and subscribed his name to it another question is immediately given. . . The examiners are not seated, but keep moving round the tables, both to judge how matters proceed and to deliver their questions at proper intervals. The examination, which embraces arithmetic, algebra, fluxions, the doctrine of infinitesimals and increments, geometry, trigonometry, mechanics, hydrostatics, optics, and astronomy, in all their various gradations, is varied according to circumstances: no one can anticipate a question, for in the course of five minutes he may be dragged from Euclid to Newton, from the humble arithmetic of Bonnycastle to the abstruse analytics of Waring. While this examination is proceeding at the three CH. VII] THE MATHEMATICAL TRIPOS. 187 tables between the hours of eight and nine, printed problems are delivered to each person of the first and second classes; these he takes with him to any window he pleases, where there are pens, ink, and paper prepared for his operations. The examination began at eight. At nine o'clock the papers had to be given up, and half-an-hour was allowed for breakfast. At half-past nine the candidates came back, and were examined in the way described above till eleven, when the Senate-House was again cleared. An interval of two hours then took place. At one o'clock all

returned to be again examined. At three the Senate-House was cleared for half-an-hour, and, on the return of the candidates, the examination was continued till five. At seven in the evening the first four classes went to the senior moderator's rooms to solve problems. They were finally dismissed for the day at nine, after eight hours of examination. The work of Tuesday was similar to that of Monday: Wednesday was partly devoted to logic and moral philosophy. At eight o'clock on Thursday morning a first list was published with all candidates of about equal merits bracketed. Until nine o'clock a candidate had the right to challenge anyone above him to an examination to see which was the better. At nine a second list came out, and a candidate's right of challenge was then confined to the bracket immediately above his own. If he proved himself the equal of the man so challenged his name was transferred to the upper bracket. To challenge and then to fail to substantiate the claim to removal to a higher bracket was considered rather ridiculous. Revised lists were published at 11 a.m., 3 p.m., and 5 p.m., according to the results of the examination during that day. At five the whole examination ended. The proctors, moderators, and examiners then retired to a room under the Public Library to prepare the list of honours, which was sometimes settled without much difficulty in a few hours, but sometimes not before 2 a.m. or 3 a.m. the next morning. The name of the senior wrangler was generally announced at midnight, and the rest of the list the next morning. In 1802 there were eighty-six candidates for honours, and they were divided into fifteen brackets, the first and second brackets containing each one name only, and the third bracket four names. It is clear from the above account that the competition fostered by the examination had developed so much as to threaten to impair its usefulness as guiding the studies of the men. On the other hand, there can be no doubt that the carefully devised arrangements for obtaining an accurate order of merit stimulated the best men to throw all their 188 THE MATHEMATICAL TRIPOS. [CH. VII energies into the work for the examination. It is easy to point out the usual double-edged result of a strict order of merit. The problem before the University was to retain its advantages while checking any abuses to which it might lead. It was the privilege of the moderators to entertain the proctors and some of the leading resident mathematicians the night before the issue of the final list, and to communicate that list in confidence to their guests. This pleasant custom survived till 1884. I revived the practice in 1890 when acting as senior moderator, but it seems to have now ceased. In 1806 Sir Frederick Pollock was senior wrangler, and in 1869 in answer to an appeal from De Morgan for an account of the mathematical study of men at the beginning of the century he wrote a letter* which is sufficiently interesting to bear reproduction: I shall write in answer to your inquiry, all about my books, my studies, and my degree, and leave you to settle all about the proprieties which my letter may give rise to, as to egotism, modesty, &c. The only books I read the first year were Wood's

Algebra (as far as quadratic equations), Bonnycastle's ditto, and Euclid (Simpson's). In the second year I read Wood (beyond quadratic equations), and Wood and Vince, for what they called the branches. In the third year I read the Jesuit's Newton and Vince's Fluxions; these were all the books, but there were certain mss. floating about which I copied—which belonged to Dealtry, second wrangler in Kempthorne's year. I have no doubt that I had read less and seen fewer books than any senior wrangler of about my time, or any period since; but what I knew I knew thoroughly, and it was completely at my fingers' ends. I consider that I was the last geometrical and fluxional senior wrangler; I was not up to the differential calculus, and never acquired it. I went up to college with a knowledge of Euclid and algebra to quadratic equations, nothing more; and I never read any second year's lore during my first year, nor any third year's lore during my second; my forte was, that what I did know I could produce at any moment with perfect accuracy. I could repeat the first book of Euclid word by word and letter by letter. During my first year I was not a 'reading' man (so called); I had no expectation of honours or a fellowship, and I attended all the lectures on all subjects—Harwood's anatomical, Woollaston's chemical, and Farish's mechanical lectures—but the examination at the end of the first year revealed to me my powers. I was not only in the first class, but it was generally understood I was first in the first class; neither I nor any one for me expected I should get in at all. Now, as I had taken no pains to prepare (taking, however, marvellous pains while the examination was going * Memoir of A. de Morgan, London, 1882, pp. 387–392. CH. VII] THE MATHEMATICAL TRIPOS. 189 on), I knew better than any one else the value of my examination qualities (great rapidity and perfect accuracy); and I said to myself, 'If you're not an ass, you'll be senior wrangler;' and I took to 'reading' accordingly. A curious circumstance occurred when the Brackets came out in the Senatehouse declaring the result of the examination: I saw at the top the name of Walter bracketed alone (as he was); in the bracket below were Fiott, Hustler , Jephson. I looked down and could not find my own name till I got to Bolland, when my pride took fire, and I said, 'I must have beaten that man, so I will look up again;' and on looking up carefully I found the nail had been passed through my name, and I was at the top bracketed alone, even above Walter. You may judge what my feelings were at this discovery; it is the only instance of two such brackets, and it made my fortune—that is, made me independent, and gave me an immense college reputation. It was said I was more than half of the examination before any one else. The two moderators were Hornbuckle, of St John's, and Brown (Saint Brown), of Trinity. The Johnian congratulated me. I said perhaps I might be challenged; he said, 'Well, if you are you're quite safe—you may sit down and do nothing, and no one would get up to you in a whole day.'. . . Latterly the Cambridge examinations seem to turn upon very different matters from what prevailed in my time. I think a Cambridge education has

for its object to make good members of society—not to extend science and make profound mathematicians. The tripos questions in the Senatehouse ought not to go beyond certain limits, and geometry ought to be cultivated and encouraged much more than it is. To this De Morgan replied: Your letter suggests much, because it gives possibility of answer. The branches of algebra of course mainly refer to the second part of Wood, now called the theory of equations. Waring was his guide. Turner—whom you must remember as head of Pembroke, senior wrangler of 1767— told a young man in the hearing of my informant to be sure and attend to quadratic equations. 'It was a quadratic,' said he, 'made me senior wrangler.' It seems to me that the Cambridge revivers were Waring, Paley, Vince, Milner. You had Dealtry's mss. He afterwards published a very good book on fluxions. He merged his mathematical fame in that of a Claphamite Christian. It is something to know that the tutor's ms. was in vogue in 1800–1806. Now—how did you get your conic sections? How much of Newton did you read? From Newton direct, or from tutor's manuscript? Surely Fiott was our old friend Dr Lee. I missed being a pupil of Hustler by a few weeks. He retired just before I went up in February 1823. The echo of Hornbuckle's answer to you about the challenge has lighted on Whewell, who, it is said, wanted to challenge Jacob, and was answered that he could not beat [him] if he were to write the whole day 190 THE MATHEMATICAL TRIPOS. [CH. VII and the other wrote nothing. I do not believe that Whewell would have listened to any such dissuasion. I doubt your being the last fluxional senior wrangler. So far as I know, Gipps, Langdale, Alderson, Dicey, Neale, may contest this point with you. The answer of Sir Frederick Pollock to these questions is dated August 7, 1869, and is as follows. You have put together as revivers five very different men. Woodhouse was better than Waring, who could not prove Wilson's (Judge of C.P.) guess about the property of prime numbers; but Woodhouse (I think) did prove it, and a beautiful proof it is. Vince was a bungler, and I think utterly insensible of mathematical beauty. Now for your questions. I did not get my conic sections from Vince. I copied a ms. of Dealtry. I fell in love with the cone and its sections, and everything about it. I have never forsaken my favourite pursuit; I delighted in such problems as two spheres touching each other and also the inside of a hollow cone, &c. As to Newton, I read a good deal (men now read nothing), but I read much of the notes. I detected a blunder which nobody seemed to be aware of. Tavel, tutor of Trinity, was not; and he argued very favourably of me in consequence. The application of the Principia I got from mss. The blunder was this: in calculating the resistance of a globe at the end of a cylinder oscillating in a resisting medium they had forgotten to notice that there is a difference between the resistance to a globe and a circle of the same diameter. The story of Whewell and Jacob cannot be true. Whewell was a very, very considerable man, I think not a great man. I have no doubt Jacob beat him in accuracy, but the supposed answer cannot be true; it is a

mere echo of what actually passed between me and Hornbuckle on the day the Tripos came out—for the truth of which I vouch. I think the examiners are taking too practical a turn; it is a waste of time to calculate actually a longitude by the help of logarithmic tables and lunar observations. It would be a fault not to know how, but a greater to be handy at it. A few minor changes in the Senate-House examinations were made in 1808* . A fifth day was added to the examination. Of the five days thus given up to it three were devoted to mathematics, one to logic, philosophy, and religion, and one to the arrangement of the brackets. Apart from the evening paper the examination on each of the first three days lasted six hours. Of these eighteen hours, eleven were assigned to book-work and seven to problems. The problem papers were set from 6 to 10 in the evening. * See Graces, December 15, 1808. CH. VII] THE MATHEMATICAL TRIPOS. 191 A letter from Whewell dated January 19, 1816, describes his examination in the Senate-House* . Jacob. Whewell. Such is the order in which we are fixed after a week's examination. . . I had before been given to understand that a great deal depended upon being able to write the greatest possible quantity in the smallest time, but of the rapidity which was actually necessary I had formed the most distant idea. I am upon no occasion a quick writer, and upon subjects where I could not go on without sometimes thinking a little I soon found myself considerably behind. I was therefore surprised, and even astonished, to find myself bracketed off, as it is called, in the second place; that is, on the day when a new division of the classes is made for the purpose of having a closer examination of the respective merits of men who come pretty near to each other, I was not classed with anybody, but placed alone in the second bracket. The man who is at the head of the list is of Caius College, and was always expected to be very high, though I do not know that anybody expected to see him so decidedly superior as to be bracketed off by himself. The tendency to cultivate mechanical rapidity was a grave evil, and lasted long after Whewell's time. According to rumour the highest honours in 1845 were obtained, to the general regret of the University, by assiduous practice in writing† . The devotion of the Cambridge school to geometrical and fluxional methods has led to its isolation from contemporary continental mathematicians. Early in the nineteenth century the evil consequence of this began to be recognized; and it was felt to be little less than a scandal that the researches of Lagrange, Laplace, and Legendre were unknown to many Cambridge mathematicians save by repute. An attempt to explain the notation and methods of the calculus as used on the Continent was made by R. Woodhouse, who stands out as the apostle of the new movement. It is doubtful if he could have brought analytical methods into vogue by himself; but his views were enthusiastically adopted by three students, Peacock, Babbage, and Herschel, who succeeded in carrying out the reforms he had suggested. They created an Analytical Society which Babbage explained was formed to advocate "the

principles of pure d-ism as opposed to the dot-age of the University." The character of the instruction in mathematics at the University has at all * S. Douglas, Life of W. Whewell, London, 1881, p. 20. † For a contemporary account of this see C.A. Bristed, Five Years in an English University, New York, 1852, pp. 233–239. 192 THE MATHEMATICAL TRIPOS. [CH. VII times largely depended on the text-books then in use, and the importance of good books of this class was emphasized by a traditional rule that questions should not be set on a new subject in the tripos unless it had been discussed in some treatise suitable and available for Cambridge students* . Hence the importance attached to the publication of the work on analytical trigonometry by Woodhouse in 1809, and of the works on the differential calculus issued by members of the Analytical Society in 1816 and 1820. In 1817 Peacock, who was moderator, introduced the symbols for differentiation into the papers set in the Senate-House examination. But his colleague continued to use the fluxional notation. Peacock himself wrote on March 17 of 1817 (i.e. shortly after the examination) on the subject as follows† : I assure you. . . that I shall never cease to exert myself to the utmost in the cause of reform, and that I will never decline any office which may increase my power to effect it. I am nearly certain of being nominated to the office of Moderator in the year 1818–19, and as I am an examiner in virtue of my office, for the next year I shall pursue a course even more decided than hitherto, since I shall feel that men have been prepared for the change, and will then be enabled to have acquired a better system by the publication of improved elementary books. I have considerable influence as a lecturer, and I will not neglect it. It is by silent perseverance only that we can hope to reduce the many-headed monster of prejudice, and make the University answer her character as the loving mother of good learning and science. In 1818 all candidates for honours, that is, all men in the first six preliminary classes, were allowed to attempt the problems: this change was made by the moderators. In 1819 G. Peacock, who was again moderator, induced his colleague to adopt the new notation. It was employed in the next year by Whewell, and in the following year by Peacock again. Henceforth the calculus in its modern language and analytical methods were freely used, new subjects were introduced, and for many years the examination provided a mathematical training fairly abreast of the times. By this time the disputations had ceased to have any immediate effect on a man's place in the tripos. Thus Whewell‡ , writing about * See ex. gr., the Grace of November 14, 1827, referred to below. † Proceedings of the Royal Society, London, 1859, vol. ix, pp. 538–9. ‡ Whewell's Writings and Correspondence, ed. Todhunter, London, 1876, vol. ii, p. 36. CH. VII] THE MATHEMATICAL TRIPOS. 193 his duties as moderator in 1820, said: You would get very exaggerated ideas of the importance attached to it [an Act] if you were to trust Cumberland; I believe it was formerly more thought of than it is now. It does not, at least immediately, produce any effect on a man's place in the tripos, and is therefore

considerably less attended to than used to be the case, and in most years is not very interesting after the five or six best men: so that I look for a considerable exercise of, or rather demand for, patience on my part. The other part of my duty in the Senate House consists in manufacturing wranglers, senior optimes, etc. and is, while it lasts, very laborious. Of the examination itself in this year he wrote as follows* : The examination in the Senate House begins to-morrow, and is rather close work while it lasts. We are employed from seven in the morning till five in the evening in giving out questions and receiving written answers to them; and when that is over, we have to read over all the papers which we have received in the course of the day, to determine who have done best, which is a business that in numerous years has often kept the examiners up the half of every night; but this year is not particularly numerous. In addition to all this, the examination is conducted in a building which happens to be a very beautiful one, with a marble floor and a highly ornamented ceiling; and as it is on the model of a Grecian temple, and as temples had no chimneys, and as a stove or a fire of any kind might disfigure the building, we are obliged to take the weather as it happens to be, and when it is cold we have the full benefit of it—which is likely to be the case this year. However, it is only a few days, and we have done with it. A sketch of the examination in the previous year from the point of view of an examinee was given by J.M.F. Wright† , but there is nothing of special interest in it. Sir George Airy‡ gave the following sketch of his recollections of the reading and studies of undergraduates of his time and of the tripos of 1823, in which he had been senior wrangler: At length arrived the Monday morning on which the examination for the B.A. degree was to begin. . . . We were all marched in a body to the Senate-House and placed in the hands of the Moderators. How the “candidates for honours” were separated from the oΈ πολλοÐ I do not know, I presume that the Acts and the Opponencies had something to do with it. The honour candidates were divided into six groups: and of these Nos. 1 and 2 (united), Nos. 3 and 4 (united), and Nos. 5 and 6 (united), * S. Douglas, Life of Whewell, London, 1881, p. 56. † Alma Mater, London, 1827, vol. ii, pp. 58–98. ‡ See Nature, vol. 35, Feb. 24, 1887, pp. 397–399. 194 THE MATHEMATICAL TRIPOS. [CH. VII received the questions of one Moderator. No. 1, Nos. 2 and 3 (united), Nos. 4 and 5 (united), and No. 6, received those of the other Moderator. The Moderators were reversed on alternate days. There were no printed question-papers: each examiner had his bound manuscript of questions, and he read out his first question; each of the examinees who thought himself able proceeded to write out his answer, and then orally called out “Done.” The Moderator, as soon as he thought proper, proceeded with another question. I think there was only one course of questions on each day (terminating before 3 o’clock, for the Hall dinner). The examination continued to Friday mid-day. On Saturday morning, about 8 o’clock, the list of honours (manuscript) was nailed on the door of

the Senate-House. It must be remembered that for students pursuing the normal course the Senate-House examination still provided the only avenue to a degree. That examination involved a knowledge of the elements of moral philosophy and theology, an acquaintance with the rules of formal logic, and the power of reading and writing scholastic Latin, but mathematics was the predominant subject, and this led to a certain one-sidedness in education. The evil of this was generally recognized, and in 1822 various reforms were introduced in the University curriculum; in particular the Previous Examination was established for students in their second year, the subjects being prescribed Greek and Latin works, a Gospel, and Paley's Evidences. Set classical books were introduced in the final examination of poll-men; and another honour or tripos examination was established for classical students. These alterations came into effect in 1824; and henceforth the Senate-House examination, so far as it related to mathematical students, was known as the Mathematical Tripos. In 1827 the scheme of examination in the Mathematical Tripos was revised. By regulations* which came into operation in January, 1828, another day was added, so that the examination extended over four days, exclusive of the day of arranging the brackets; the number of hours of examination was twenty-three, of which seven were assigned to problems. On the first two days all the candidates had the same questions proposed to them, inclusive of the evening problems, and the examination on those days excluded the higher and more difficult parts of mathematics, in order, in the words of the report, "that the candidates for honours may not be induced to pursue the more abstruse and profound mathematics, to the neglect of more elementary knowl- * See the Grace, November 14, 1827. CH. VII] THE MATHEMATICAL TRIPOS. 195 edge." Accordingly, only such questions as could be solved without the aid of the differential calculus were set on the first day, and those set on the second day involved only its elementary applications. The classes were reduced to four, determined as before by the exercises in the schools. The regulations of 1827 definitely prescribed that all the papers should be printed. They are also noticeable as being the last which gave the examiners power to ask vivâ voce questions, though such questions were restricted to "propositions contained in the mathematical works commonly in use in the University, or examples and explanations of such propositions." It was further recommended that no paper should contain more questions than well-prepared students could be expected to answer within the time allowed for it, but that if any candidate, before the end of the time, had answered all the questions in the paper, the examiners might propose additional questions vivâ voce. The power of granting honorary optime degrees now ceased; it had already fallen into abeyance. Henceforth the examination was conducted under definite rules, and I no longer concern myself with the traditions of the examination. In the same year as these changes became effective the examination for the poll degree was separated from the

tripos with different sets of papers and a different schedule of subjects* . It was, however, still nominally considered as forming part of the Senate-House examination, and until 1858 those who obtained a poll degree were arranged in four classes, described as fourth, fifth, sixth, and seventh, as if in continuation of the junior optimes or third class of the tripos. The year 1828 therefore shews us the Senate-House examination dividing into two distinct parts; one known as the mathematical tripos, the other as the poll examination. In 18511 the classical tripos was made independent of the mathematical tripos, and thus provided a separate avenue to a degree. Historically, the examination usually known as “the General” represents the old Senate-House examination for the poll-men, but gradually it has been moved to an earlier period in the normal course taken by the men. In 1852 another set of examinations, at first called “the professor’s examinations,” and now somewhat modified and known as “the Specials,” was instituted for all poll-men to take before they could qualify for * See Grace, May 21, 1828, confirming a Report of March 27, 1828. 1. ‘1850’ corrected to ‘1851’ as per errata sheet 196 THE MATHEMATICAL TRIPOS. [CH. VII a degree. In 1858 the fiction that the poll-examinations were part of the Senate-House examination was abandoned, and subsequently they have been treated as providing an independent method of obtaining the degree: thus now the mathematical tripos is the sole representative of the old Senate-House examination. Since 1858 numerous other ways of obtaining the degree have been established, and it is now possible to get it by shewing proficiency in very special, or even technical subjects. Further changes in the mathematical tripos were introduced in 1833* . The duration of the examination, before the issue of the brackets, was extended to five days, and the number of hours of examination on each day was fixed at five and a-half. Seven and a-half hours were assigned to problems. The examination on the first day was confined to subjects that did not require the differential calculus, and only the simplest applications of the calculus were permitted on the second and third days. During the first four days of the examination the same papers were set to all the candidates alike, but on the fifth day the examination was conducted according to classes. No reference was made to vivâ voce questions, and the preliminary classification of the brackets only survived in a permission to re-examine candidates if it were found necessary. This permissive rule remained in force till 1848, but I believe that in fact it was never used. In December, 1834, a few unimportant details were amended. Mr Earnshaw, the senior moderator in 1836, informed me that he believed that the tripos of that year was the earliest one in which all the papers were marked, and that in previous years the examiners had partly relied on their impression of the answers given. New regulations came into force† in 1839. The examination now lasted for six days, and continued as before for five hours and a-half each day. Eight and a-half hours were assigned to problems. Throughout the whole examination the same papers were set to all

candidates, and no reference was made to any preliminary classes. It was no doubt in accordance with the spirit of these changes that the acts in the schools should be abolished, but they were discontinued by the moderators of 1839 without the authority of the Senate. The examination was for the future confined‡ to mathematics. * See the Grace of April 6, 1832. † See Grace of May 30, 1838. ‡ Under a badly-worded grace passed on May 11, 1842, on the recommendation of CH. VII] THE MATHEMATICAL TRIPOS. 197 In the same year in which the new scheme came into force a proposal to again reopen the subject was rejected (March 6). The difficulty of bringing professorial lectures into relation with the needs of students has more than once been before the University. The desirability of it was emphasized by a Syndicate in February, 1843, which recommended conferences at stated intervals between the mathematical professors and examiners. This report foreshadowed the creation of a Mathematical Board, but it was rejected by the Senate on March 31. A few years later the scheme of the examination was again reconstructed by regulations* which came into effect in 1848. The duration of the examination was extended to eight days. The examination lasted in all forty-four and a-half hours, twelve of which were devoted to problems. The first three days were assigned to specified elementary subjects; in the papers set on these days riders were to be set as well as bookwork, but the methods of analytical geometry and the calculus were excluded. After the first three days there was a short interval, at the end of which the examiners issued a list of those who had so acquitted themselves as to deserve mathematical honours. Only those whose names were contained in this list were admitted to the last five days of the examination, which was devoted to the higher parts of mathematics. After the conclusion of the examination the examiners, taking into account the whole eight days, brought out the list arranged in order of merit. No provision was made for any rearrangement of this list corresponding to the examination of the brackets. The arrangements of 1848 remained in force till 1873. In the same year as these regulations came into force, a Board of Mathematical Studies (consisting of the mathematical professors, and the moderators and examiners for the current year and the two preceding years) was constituted† by the Senate. From that time forward their minutes supply a permanent record of the changes gradually introduced into the tripos. I do not allude to subsequent changes which only concern unimportant details of the examination. a syndicate on theological studies, candidates for mathematical honours were, after 1846, required to attend the poll examination on Paley’s Moral Philosophy, the New Testament and Ecclesiastical History. This had not been the intention of the Senate, and on March 14, 1855, a grace was passed making this clear. * See Grace of May 13, 1846, confirming a report of March 23, 1846. † See Grace of October 31, 1848. 198 THE MATHEMATICAL TRIPOS. [CH. VII In May, 1849, the Board issued a report in which, after giving a review of the past and existing state of the

mathematical studies in the University, they recommended that the mathematical theories of electricity, magnetism, and heat should not be admitted as subjects of examination. In the following year they issued a second report, in which they recommended the omission of elliptical integrals, Laplace's coefficients, capillary attraction, and the figure of the earth considered as heterogeneous, as well as a definite limitation of the questions in lunar and planetary theory. In making these recommendations the Board were only giving expression to what had become the practice in the examination. I may, in passing, mention a curious attempt which was made in 1853 and1 1854 to assist candidates in judging of the relative difficulty of the questions asked. This was effected by giving to the candidates, at the same time as the examination paper, a slip of paper on which the marks assigned for the bookwork and rider for each question were printed. I mention the fact merely because these things are rapidly forgotten and not because it is of any intrinsic value. I possess a complete set of slips which came to me from Dr Todhunter. In 1856 there was an amusing difference of opinion between the Vice-Chancellor and the moderators. The Vice-Chancellor issued a notice to say that for the convenience of the University he had directed the tripos lists to be published at 8.0 a.m. as well as at 9.0 a.m., but when the University arrived at 8.0 the moderators said that they should not read the list until 9.0. Considerable changes in the scheme of examination were introduced in 1873. On December 5, 1865, the Board had recommended the addition of Laplace's coefficients and the figure of the earth considered as heterogeneous as subjects of the examination; the report does not seem to have been brought before the Senate, but attention was called to the fact that certain departments of mathematics and mathematical physics found no place in the tripos schedules, and were neglected by most students. Accordingly a syndicate was appointed on June 6, 1867, to consider the matter, and a scheme drawn up by them was approved in 1868* and came into effect in 1873. The new scheme of examination * See Grace of June 2, 1868. It was carried by a majority of only five in a house of 75. 1. '1853 and' inserted as per errata sheet CH. VII] THE MATHEMATICAL TRIPOS. 199 was framed on the same lines as that of 1848. The subjects in the first three days were left unchanged, but an extra day was added, devoted to the elements of mathematical physics. The essence of the modification was the greatly extended range of subjects introduced into the schedule of subjects for the last five days, and their arrangement in divisions, the marks awarded to the five divisions being approximately those awarded to the three days in proportion to 2, 1, 1, 1, 2/3 to 1 respectively. Under the new regulations the number of examiners was increased from four to five. The assignment of marks to groups of subjects was made under the impression that the best candidates would concentrate their abilities on a selection of subjects from the various divisions. But it was found that, unless the questions were made extremely difficult, more marks could be obtained by reading

superficially all the subjects in the five divisions than by attaining real proficiency in a few of the higher ones: while the wide range of subjects rendered it practically impossible to thoroughly cover all the ground in the time allowed. The failure was so pronounced that in 1877 another syndicate was appointed to consider the mathematical studies and examinations of the University. They presented an elaborate scheme, but on May 13, 1878, some of the most important parts of it were rejected and their subsequent proposals, accepted on November 21, 1878 (by 62 to 49), represented a compromise which pleased few members of the Senate* . Under the new scheme which came into force in 1882 the tripos was divided into two portions: the first portion was taken at the end of the third year of residence, the range of subjects being practically the same as in the regulations of 1848, and the result brought out in the customary order of merit. The second portion was held in the following January, and was open only to those who had been wranglers in the preceding June. This portion was confined to higher mathematics and appealed chiefly to specialists. The result was brought out in three classes, each arranged in alphabetical order. The moderators and examiners conducted the whole examination without any extraneous aid. In the next year or two further amendments were made† , moving * See Graces of May 17, 1877; May 29, 1878; and November 21, 1878: and the Cambridge University Reporter, April 2, May 14, June 4, October 29, November 12, and November 26, 1878. † See the Graces of December 13, 1883; June 12, 1884; February 10, 1885; October 29, 1885; and June 1, 1886. 200 THE MATHEMATICAL TRIPOS. [CH. VII the second part to the June of the fourth year, throwing it open to all men who had graduated in the tripos of the previous June, and transferring the conduct of the examination in Part 2 to four examiners nominated by the Board: this put it largely under the control of the professors. The range of subjects of Part 2 was also greatly extended, and candidates were encouraged to select only a few of them. It was further arranged that Part 1 might be taken at the end of a man’s second year of residence, though in that case it would not qualify for a degree. A student who availed himself of this leave could take Part 2 at the end either of his third or of his fourth year as he pleased. The tripos is still (1905) carried on under the scheme of 1886. The general effect of these changes was to destroy the homogeneity of the tripos. Objections to the new scheme were soon raised. Especially, it was said—whether rightly or wrongly—that Part 1 contained too many technical subjects to serve as a general educational training for any save mathematicians; that the distinction of a high place in the historic list produced on its results tended to prevent the best men taking it in their second year, though by this time they had read sufficiently to be able to do so; and that Part 2 was so constructed as to appeal only to professional mathematicians, and that thus the higher branches of mathematics were neglected by all save a few specialists. Whatever value be attached to these opinions,

the number of students studying mathematics fell rapidly under the scheme of 1886. In 1899 the Board proposed* further changes. These seemed to some members of the Senate to be likely to still further decrease the number of men who took up the subject as one of general education. At any rate the two main proposals were rejected (February 15, 1900) by votes of 151 to 130 and 161 to 129. The curious origin of the term tripos has been repeatedly told, and an account of it may fitly close this chapter. Formerly there were three principal occasions on which questionists were admitted to the title or degree of bachelor. The first of these was the comitia priora, held on Ash-Wednesday, for the best men in the year. The next was the comitia posteriora, which was held a few weeks later, and at which any student who had distinguished himself in the quadragesimal exercises subsequent to Ash-Wednesday had his seniority reserved to him. Lastly, there was the comitia minora, for students who had in no special way * See Reports dated November 7, 1899, and January 20, 1900. CH. VII] THE MATHEMATICAL TRIPOS. 201 distinguished themselves. In the fifteenth century an important part in the ceremony on each of these occasions was taken by a certain “ould bachilour,” who sat upon a three-legged stool or tripos before the proctors and tested the abilities of the would-be graduates by arguing some question with the “eldest son,” who was selected from them as their representative. To assist the latter in what was often an unequal contest his “father,” that is, the officer of his college who was to present him for his degree, was allowed to come to his assistance. Originally the ceremony was a serious one, and had a certain religious character. It took place in Great St Mary’s Church, and marked the admission of the student to a position with new responsibilities, while the season of Lent was chosen with a view to bring this into prominence. The Puritan party objected to the observance of such ecclesiastical ceremonies, and in the course of the sixteenth century they introduced much license and buffoonery into the proceedings. The part played by the questionist became purely formal. A serious debate still sometimes took place between the father of the senior questionist and a regent master who represented the University; but the discussion was prefaced by a speech by the bachelor, who came to be called Mr Tripos just as we speak of a judge as the bench, or of a rower as an oar. Ultimately public opinion permitted Mr Tripos to say pretty much what he pleased, so long as it was not dull and was scandalous. The speeches he delivered or the verses he recited were generally preserved by the Registrary, and were known as the tripos verses: originally they referred to the subjects of the disputations then propounded. The earliest copies now extant are those for 1575. The University officials, to whom the personal criticisms in which the tripos indulged were by no means pleasing, repeatedly exhorted him to remember “while exercising his privilege of humour, to be modest withal.” In 1740, says Mr Mullinger* , “the authorities after condemning the excessive license of the tripos announced that the comitia at Lent

would in future be conducted in the Senate-House; and all members of the University, of whatever order or degree, were forbidden to assail or mock the disputants with scurrilous jokes or unseemly witticisms. About the year 1747–8, the moderators initiated the practice of printing the honour lists on the back of the sheets containing the * J.B. Mullinger, The University of Cambridge, Cambridge, vol. i, 1873, pp. 175, 176. 202 THE MATHEMATICAL TRIPOS. [CH. VII tripos verses, and after the year 1755 this became the invariable practice. By virtue of this purely arbitrary connection these lists themselves became known as the tripos; and eventually the examination itself, of which they represented the results, also became known by the same designation." The tripos ceased to deliver his speech about 1750, but the issue of tripos verses continued for nearly 150 years longer. During the latter part of this time they consisted of four sets of verses, usually in Latin, but occasionally in Greek, in which current topics in the University were treated lightly or seriously as the writer thought fit. They were written for the proctors and moderators by undergraduates or commencing bachelors, who were supposed each to receive a pair of white kid gloves in recognition of their labours. Thus gradually the word tripos changed its meaning "from a thing of wood to a man, from a man to a speech, from a speech to sets of verses, from verses to a sheet of coarse foolscap paper, from a paper to a list of names, and from a list of names to a system of examination* ." In 1895 the proctors and moderators, without consulting the Senate, sent in no verses, and thus, in spite of widespread regret, an interesting custom of many centuries standing was destroyed. No doubt it may be argued that the custom had never been embodied in statute or ordinance, and thus was not obligatory. Also it may be said that its continuance was not of material benefit to anybody. I do not think that such arguments are conclusive, and personally I regret the disappearance of historic ties unless it can be shown that they cause inconvenience, which of course in this case could not be asserted. * Wordsworth, Scholae Academicae, Cambridge, 1877, p. 21. CHAPTER VIII. THREE GEOMETRICAL PROBLEMS. Among the more interesting geometrical problems of antiquity are three questions which attracted the special attention of the early Greek mathematicians. Our knowledge of geometry is derived from Greek sources, and thus these questions have attained a classical position in the history of the subject. The three questions to which I refer are (i) the duplication of a cube, that is, the determination of the side of a cube whose volume is double that of a given cube; (ii) the trisection of an angle; and (iii) the squaring of a circle, that is, the determination of a square whose area is equal to that of a given circle—each problem to be solved by a geometrical construction involving the use of straight lines and circles only, that is, by Euclidean geometry. With the restriction last mentioned all three problems are insoluble† . To duplicate a cube the length of whose side is a, we have to find a line of length x, such that $x^3 = 2a^3$. Again, to trisect a given angle, we may proceed to

find the sine of the angle, say a, then, if x is the sine of an angle equal to one-third of the given angle, we have 4x 3 = 3x − a. Thus the first and second problems, when considered analytically, require the solution of a cubic equation; and since a construction by means of circles (whose equations are of the form x 2 + y 2 + ax + by + c = 0) and straight lines (whose equations are of the form αx + βy + γ = 0) cannot be equivalent to the solution of a cubic equation, it is inferred that the problems are insoluble if in our † F. Klein, Vorträge über ausgewählte Fragen der Elementargeometrie, Leipzig, 1895. 203 204 THREE GEOMETRICAL PROBLEMS. [CH. VIII constructions we are restricted to the use of circles and right lines. If the use of the conic sections is permitted, both of these questions can be solved in many ways. The third problem is different in character, but under the same restrictions it also is insoluble. I propose to give some of the constructions which have been proposed for solving the first two of these problems. To save space, I shall not draw the necessary diagrams, and in most cases I shall not add the proofs: the latter present but little difficulty. I shall conclude with some historical notes on approximate solutions of the quadrature of the circle. The Duplication of the Cube* . The problem of the duplication of the cube was known in ancient times as the Delian problem, in consequence of a legend that the Delians had consulted Plato on the subject. In one form of the story, which is related by Philoponus† , it is asserted that the Athenians in 430 b.c., when suffering from the plague of eruptive typhoid fever, consulted the oracle at Delos as to how they could stop it. Apollo replied that they must double the size of his altar which was in the form of a cube. To the unlearned suppliants nothing seemed more easy, and a new altar was constructed either having each of its edges double that of the old one (from which it followed that the volume was increased eight-fold) or by placing a similar cubic altar next to the old one. Whereupon, according to the legend, the indignant god made the pestilence worse than before, and informed a fresh deputation that it was useless to trifle with him, as his new altar must be a cube and have a volume exactly double that of his old one. Suspecting a mystery the Athenians applied to Plato, who referred them to the geometricians. The insertion of Plato's name is an obvious anachronism. Eratosthenes‡ relates a somewhat similar story, but with Minos as the propounder of the problem. * See Historia Problematis de Cubi Duplicatione by N.T. Reimer, Göttingen, 1798; and Historia Problematis Cubi Duplicandi by C.H. Biering, Copenhagen, 1844: also Das Delische Problem, by A. Sturm, Linz, 1895–7. Some notes on the subject are given in my History of Mathematics. † Philoponus ad Aristotelis Analytica Posteriora, bk. i, chap. vii. ‡ Archimedis Opera cum Eutocii Commentariis, ed. Torelli, Oxford, 1792, p. 144; ed. Heiberg, Leipzig, 1880–1, vol. iii, pp. 104–107. CH. VIII] THE DUPLICATION OF THE CUBE. 205 In an Arab work, the Greek legend was distorted into the following extraordinarily impossible piece of history, which I cite as a curiosity of its kind. "Now in the days of Plato," says the writer, "a

plague broke out among the children of Israel. Then came a voice from heaven to one of their prophets, saying, ‘Let the size of the cubic altar be doubled, and the plague will cease’; so the people made another altar like unto the former, and laid the same by its side. Nevertheless the pestilence continued to increase. And again the voice spake unto the prophet, saying, ‘They have made a second altar like unto the former, and laid it by its side, but that does not produce the duplication of the cube.’ Then applied they to Plato, the Grecian sage, who spake to them, saying, ‘Ye have been neglectful of the science of geometry, and therefore hath God chastised you, since geometry is the most sublime of all the sciences.’ Now, the duplication of a cube depends on a rare problem in geometry, namely. . . ”. And then follows the solution of Apollonius, which is given later. If a is the length of the side of the given cube and x that of the required cube, we have x 3 = 2a 3 , that is, x : a = √3 2 : 1. It is probable that the Greeks were aware that the latter ratio is incommensurable, in other words, that no two integers can be found whose ratio is the same as that of √3 2 : 1, but it did not therefore follow that they could not find the ratio by geometry: in fact, the side and diagonal of a square are instances of lines whose numerical measures are incommensurable. I proceed now to give some of the geometrical constructions which have been proposed for the duplication of the cube* . With one exception, I confine myself to those which can be effected by the aid of the conic sections. Hippocrates† (circ. 420 b.c.) was perhaps the earliest mathematician who made any progress towards solving the problem. He did not give a geometrical construction, but he reduced the question to that of finding two means between one straight line (a), and another twice as long (2a). If these means are x and y, we have a : x = x : y = y : 2a, from which it follows that x 3 = 2a 3 . It is in this form that the problem * On the application to this problem of the traditional Greek methods of analysis by Hero and Philo (leading to the solution by the use of Apollonius’s circle), by Nicomedes (leading to the solution by the use of the conchoid), and by Pappus (leading to the solution by the use of the cissoid), see Geometrical Analysis by J. Leslie, Edinburgh, second edition, 1811, pp. 247–250, 453. † Proclus, ed. Friedlein, pp. 212, 213. 206 THREE GEOMETRICAL PROBLEMS. [CH. VIII is always presented now. Formerly any process of solution by finding these means was called a mesolabum. One of the first solutions of the problem was that given by Archytas* in or about the year 400 b.c. His construction is equivalent to the following. On the diameter OA of the base of a right circular cylinder describe a semicircle whose plane is perpendicular to the base of the cylinder. Let the plane containing this semicircle rotate round the generator through O, then the surface traced out by the semicircle will cut the cylinder in a tortuous curve. This curve will itself be cut by a right cone, whose axis is OA and semi-vertical angle is (say) 60◦ , in a point P, such that the projection of OP on the base of the cylinder will be to the radius of the cylinder in the ratio of the side of

the required cube to that of the given cube. Of course the proof given by Archytas is geometrical; and it is interesting to note that in it he shows himself familiar with the results of the propositions Euc. iii, 18, iii, 35, and xi, 19. To show analytically that the construction is correct, take OA as the axis of x, and the generator of the cylinder drawn through O as axis of z, then with the usual notation, in polar coordinates, if a is the radius of the cylinder, we have for the equation of the surface described by the semicircle r = 2a sin θ; for that of the cylinder r sin θ = 2a cos ϕ; and for that of the cone sin θ cos ϕ = 1 2 . These three surfaces cut in a point such that sin3 θ = 1 2 , and therefore (r sin θ) 3 = 2a 3 . Hence the volume of the cube whose side is r sin θ is twice that of the cube whose side is a. The construction attributed to Plato† (circ. 360 b.c.) depends on the theorem that, if CAB and DAB are two right-angled triangles, having one side, AB, common, their other sides, AD and BC, parallel, and their hypothenuses, AC and BD, at right angles, then if these hypothenuses cut in P, we have P C : P B = P B : P A = P A : P D. Hence, if such a figure can be constructed having P D = 2P C, the problem will be solved. It is easy to make an instrument by which the figure can be drawn. The next writer whose name is connected with the problem is Menaechmus‡ , who in or about 340 b.c. gave two solutions of it. In the first of these he pointed out that two parabolas having a common vertex, axes at right angles, and such that the latus rectum * Archimedis Opera, ed. Torelli, p. 143; ed. Heiberg, vol. iii, pp. 98–103. † Ibid., ed. Torelli, p. 135; ed. Heiberg, vol. iii, pp. 66–71. ‡ Ibid., ed. Torelli, pp. 141–143; ed. Heiberg, vol. iii, pp. 92–99. CH. VIII] THE DUPLICATION OF THE CUBE. 207 of the one is double that of the other will intersect in another point whose abscissa (or ordinate) will give a solution. If we use analysis this is obvious; for, if the equations of the parabolas are y 2 = 2ax and x 2 = ay, they intersect in a point whose abscissa is given by x 3 = 2a 3 . It is probable that this method was suggested by the form in which Hippocrates had cast the problem: namely, to find x and y so that a : x = x : y = y : 2a, whence we have x 2 = ay and y 2 = 2ax. The second solution given by Menaechmus was as follows. Describe a parabola of latus rectum l. Next describe a rectangular hyperbola, the length of whose real axis is 4l, and having for its asymptotes the tangent at the vertex of the parabola and the axis of the parabola. Then the ordinate and the abscissa of the point of intersection of these curves are the mean proportionals between l and 2l. This is at once obvious by analysis. The curves are x 2 = ly and xy = 2l 2 . These cut in a point determined by x 3 = 2l 3 and y 3 = 4l 3 . Hence l : x = x : y = y : 2l. The solution of Apollonius* , which was given about 220 b.c., was as follows. The problem is to find two mean proportionals between two given lines. Construct a rectangle OADB, of which the adjacent sides OA and OB are respectively equal to the two given lines. Bisect AB in C. With C as centre describe a circle cutting OA produced in a and cutting OB produced in b, so that aDb shall be a straight line. If this circle can be so described, it will follow that OA : Bb = Bb : Aa =

Aa : OB, that is, Bb and Aa are the two mean proportionals between OA and OB. It is impossible to construct the circle by Euclidean geometry, but Apollonius gave a mechanical way of describing it. The only other construction of antiquity to which I will refer is that given by Diocles and Sporus† . It is as follows. Take two sides of a rectangle OA, OB, equal to the two lines between which the means are sought. Suppose OA to be the greater. With centre O and radius OA describe a circle. Let OB produced cut the circumference in C and let AO produced cut it in D. Find a point E on BC so that if DE cuts AB produced in F and cuts the circumference in G, then F E = EG. If E can be found, then OE is the first of the means between OA and OB. Diocles invented the cissoid in order to determine E, but it can be found equally conveniently by the aid of conics. * Ibid., ed. Torelli, p. 137; ed. Heiberg, vol. iii, pp. 76–79. The solution is given in my History of Mathematics, London, 1901, p. 84. † Ibid., ed. Torelli, pp. 138, 139, 141; ed. Heiberg, vol. iii, pp. 78–84, 90–93. 208 THREE GEOMETRICAL PROBLEMS. [CH. VIII In more modern times several other solutions have been suggested. I may allude in passing to three given by Huygens* , but I will enunciate only those proposed respectively by Vieta, Descartes, Gregory of St Vincent, and Newton. Vieta's construction is as follows† . Describe a circle, centre O, whose radius is equal to half the length of the larger of the two given lines. In it draw a chord AB equal to the smaller of the two given lines. Produce AB to E so that BE = AB. Through A draw a line AF parallel to OE. Through O draw a line DOCF G, cutting the circumference in D and C, cutting AF in F, and cutting BA produced in G, so that GF = OA. If this line can be drawn then AB : GC = GC : GA = GA : CD. Descartes pointed out‡ that the curves x 2 = ay and x 2+y 2 = ay+bx cut in a point (x, y) such that a : x = x : y = y : b. Of course this is equivalent to the first solution given by Menaechmus, but Descartes preferred to use a circle rather than a second conic. Gregory's construction was given in the form of the following theorem§ . The hyperbola drawn through the point of intersection of two sides of a rectangle so as to have the two other sides for its asymptotes meets the circle circumscribing the rectangle in a point whose distances from the asymptotes are the mean proportionals between two adjacent sides of the rectangle. This is the geometrical expression of the proposition that the curves xy = ab and x 2 + y 2 = ay + bx cut in a point (x, y) such that a : x = x : y = y : b. One of the constructions proposed by Newton is as follows‖ . Let OA be the greater of two given lines. Bisect OA in B. With centre O and radius OB describe a circle. Take a point C on the circumference so that BC is equal to the other of the two given lines. From O draw ODE cutting AC produced in D, and BC produced in E, so that the intercept DE = OB. Then BC : OD = OD : CE = CE : OA. Hence OD and CE are two mean proportionals between any two lines BC and OA. * Opera Varia, Leyden, 1724, pp. 393–396. † Opera Mathematica, ed. Schooten, Leyden, 1646, prop, v, pp. 242–243. ‡ Geometria, bk. iii, ed. Schooten, Amsterdam, 1659, p. 91. § Gregory of St Vincent, Opus Geometricum

Quadraturae Circuli, Antwerp, 1647, bk. vi, prop. 138, p. 602. ‖ Arithmetica Universalis, Ralphson's (second) edition, 1728, p. 242; see also pp. 243, 245. CH. VIII] THE TRISECTION OF AN ANGLE. 209 The Trisection of an Angle* . The trisection of an angle is the second of these classical problems, but tradition has not enshrined its origin in romance. The following two constructions are among the oldest and best known of those which have been suggested; they are quoted by Pappus† , but I do not know to whom they were due originally. The first of them is as follows. Let AOB be the given angle. From any point P in OB draw PM perpendicular to OA. Through P draw P R parallel to OA. On MP take a point Q so that if OQ is produced to cut P R in R then QR = 2 ·OP. If this construction can be made, then AOR = 1 3AOB. The solution depends on determining the position of R. This was effected by a construction which may be expressed analytically thus. Let the given angle be tan−1 (b/a). Construct the hyperbola xy = ab, and the circle (x − a) 2 + (y − b) 2 = 4(a 2 + b 2). Of the points where they cut, let x be the abscissa which is greatest, then P R = x − a, and tan−1 (b/x) = 1 3 tan−1 (b/a). The second construction is as follows. Let AOB be the given angle. Take OB = OA, and with centre O and radius OA describe a circle. Produce AO indefinitely and take a point C on it external to the circle so that if CB cuts the circumference in D then CD shall be equal to OA. Draw OE parallel to CDB. Then, if this construction can be made, AOE = 1 3AOB. The ancients determined the position of the point C by the aid of the conchoid: it could be also found by the use of the conic sections. I proceed to give a few other solutions; confining myself to those effected by the aid of conics. Among the other constructions given by Pappus‡ I may quote the following. Describe a hyperbola whose eccentricity is two. Let its centre be C and its vertices A and A' . Produce CA' to S so that A'S = CA' . On AS describe a segment of a circle to contain the given angle. Let * On the bibliography of the subject see the supplements to L'Intermédiaire des Mathématiciens, Paris, May and June, 1904. † Pappus, Mathematicae Collectiones, bk. iv, props. 32, 33 (ed. Commandino, Bonn, 1670, pp. 97–99). On the application to this problem of the traditional Greek methods of analysis see Geometrical Analysis, by J. Leslie, Edinburgh, second edition, 1811, pp. 245–247. ‡ Pappus, bk. iv, prop. 34, pp. 99–104. 210 THREE GEOMETRICAL PROBLEMS. [CH. VIII the orthogonal bisector of AS cut this segment in O. With centre O and radius OA or OS describe a circle. Let this circle cut the branch of the hyperbola through A' in P. Then SOP = 1 3 SOA. In modern times one of the earliest of the solutions by a direct use of conics was suggested by Descartes, who effected it by the intersection of a circle and a parabola. His construction* is equivalent to finding the points of intersection other than the origin, of the parabola y 2 = 1 4 x and the circle x 2+y 2− 13 4 x+4ay = 0. The ordinates of these points are given by the equation 4y 3 = 3y − a. The smaller positive root is the sine of one-third of the angle whose sine is a. The demonstration is ingenious. One of the solutions proposed by Newton is practically equivalent to

the third one which is quoted above from Pappus. It is as follows† . Let A be the vertex of one branch of a hyperbola whose eccentricity is two, and let S be the focus of the other branch. On AS describe the segment of a circle containing an angle equal to the supplement of the given angle. Let this circle cut the S branch of the hyperbola in P. Then P AS will be equal to one-third of the given angle. The following elegant solution is due to Clairaut‡ . Let AOB be the given angle. Take OA = OB, and with centre O and radius OA describe a circle. Join AB, and trisect it in H, K, so that AH = HK = KB. Bisect the angle AOB by OC cutting AB in L. Then AH = 2 · HL. With focus A, vertex H, and directrix OC, describe a hyperbola. Let the branch of this hyperbola which passes through H cut the circle in P. Draw PM perpendicular to OC and produce it to cut the circle in Q. Then by the focus and directrix property we have AP : PM = AH : HL = 2 : 1, ∴ AP = 2 · PM = P Q. Hence, by symmetry, AP = P Q = QR. ∴ AOP = P OQ = QOR. I may conclude by giving the solution which Chasles§ regards as the most fundamental. It is equivalent to the following proposition. If OA and OB are the bounding radii of a circular arc AB, then a rectangular hyperbola having OA for a diameter and passing through the point of intersection of OB with the tangent to the circle at A will pass through * Geometria, bk. iii, ed. Schooten, Amsterdam, 1659, p. 91. † Arithmetica Universalis, problem xlii, Ralphson's (second) edition, London, 1728, p. 148; see also pp. 243–245. ‡ I believe that this was first given by Clairaut, but I have mislaid my reference. The construction occurs as an example in the Geometry of Conics, by C. Taylor, Cambridge, 1881, No. 308, p. 126. § Traité des sections coniques, Paris, 1865, art. 37, p. 36. CH. VIII] THE QUADRATURE OF THE CIRCLE. 211 one of the two points of trisection of the arc. The Quadrature of the Circle* . The object of the third of the classical problems was the determination of a side of a square whose area should be equal to that of a given circle. The investigation, previous to the last two hundred years, of this question was fruitful in discoveries of allied theorems, but in more recent times it has been abandoned by those who are able to realize what is required. The history of this subject has been treated by competent writers in such detail that I shall content myself with a very brief allusion to it. Archimedes showed† (what possibly was known before) that the problem is equivalent to finding the area of a right-angled triangle whose sides are equal respectively to the perimeter of the circle and the radius of the circle. Half the ratio of these lines is a number, usually denoted by π. That this number is incommensurable had been long suspected, and has been now demonstrated. The earliest analytical proof of it was given by Lambert‡ in 1761; in 1803 Legendre§ extended the proof to show that π 2 was also incommensurable; and recently Lindemann‖ has * See Montucla's Histoire des Recherches sur la Quadrature du Cercle, edited by P.L. Lacroix, Paris, 1831; also various articles by A. De Morgan, and especially his Budget of Paradoxes, London, 1872. A popular sketch of the subject has been compiled by H. Schubert, Die Quadratur des

Zirkels, Hamburg, 1889; and since the publication of the earlier editions of these Recreations Prof. F. Rudio of Zurich has given an analysis of the arguments of Archimedes, Huygens, Lambert, and Legendre on the subject, with an introduction on the history of the problem, Leipzig, 1892. † Archimedis Opera, KÔκλου μὲτρησις, prop. i, ed. Torelli, pp. 203–205; ed. Heiberg, vol. i, pp. 258–261, vol. iii, pp. 269–277. ‡ Mémoires de l'Académie de Berlin for 1761, Berlin, 1768, pp. 265–322. § Legendre's Geometry, Brewster's translation, Edinburgh, 1824, pp. 239–245. ‖ Ueber die Zahl π, Mathematische Annalen, Leipzig, 1882, vol. xx, pp. 213– 225. The proof leads to the conclusion that, if x is a root of a rational integral algebraical equation, then e x cannot be rational: hence, if πi was the root of such an equation, e πi could not be rational; but e πi is equal to −1, and therefore is rational; hence πi cannot be the root of such an algebraical equation, and therefore neither can π. 212 THREE GEOMETRICAL PROBLEMS. [CH. VIII shown that π cannot be the root of a rational algebraical equation. An earlier attempt by James Gregory to give a geometrical demonstration of this is worthy of notice. Gregory proved* that the ratio of the area of any arbitrary sector to that of the inscribed or circumscribed polygons is not expressible by a finite number of algebraical terms. Hence he inferred that the quadrature was impossible. This was accepted by Montucla, but it is not conclusive, for it is conceivable that some particular sector might be squared, and this particular sector might be the whole circle. In connection with Gregory's proposition above cited, I may add that Newton† proved that in any closed oval an arbitrary sector bounded by the curve and two radii cannot be expressed in terms of the co-ordinates of the extremities of the arc by a finite number of algebraical terms. The argument is condensed and difficult to follow: the same reasoning would show that a closed oval curve cannot be represented by an algebraical equation in polar co-ordinates. From this proposition no conclusion as to the quadrature of the circle is to be drawn, nor did Newton draw any. In the earlier editions of this work I expressed an opinion that the result presupposed a particular definition of the word oval, but on more careful reflection I think that the conclusion is valid without restriction. With the aid of the quadratrix, or the conchoid, or the cissoid, the quadrature of the circle is easy, but the construction of those curves assumes a knowledge of the value of π, and thus the question is begged. I need hardly add that, if π represented merely the ratio of the circumference of a circle to its diameter, the determination of its numerical value would have but slight interest. It is however a mere accident that π is defined usually in that way, and it really represents a certain number which would enter into analysis from whatever side the subject was approached. I recollect a distinguished professor explaining how different would be the ordinary life of a race of beings born, as easily they might be, so that the fundamental processes of arithmetic, algebra and geometry were different to those which seem to us so evident, but, he added, it is impossible to conceive of a

universe in which e and π should not exist. * Vera Circuli et Hyperbolae Quadratura, Padua, 1668: this is reprinted in Huygens's Opera Varia, Leyden, 1724, pp. 405–462. † Principia, bk. i, section vi, lemma xxviii. CH. VIII] APPROXIMATIONS TO THE VALUE OF π. 213 I have quoted elsewhere an anecdote, which perhaps will bear repetition, that illustrates how little the usual definition of π suggests its properties. De Morgan was explaining to an actuary what was the chance that a certain proportion of some group of people would at the end of a given time be alive; and quoted the actuarial formula, involving π, which, in answer to a question, he explained stood for the ratio of the circumference of a circle to its diameter. His acquaintance, who had so far listened to the explanation with interest, interrupted him and exclaimed, "My dear friend, that must be a delusion, what can a circle have to do with the number of people alive at the end of a given time?" In reality the fact that the ratio of the length of the circumference of a circle to its diameter is the number denoted by π does not afford the best analytical definition of π, and is only one of its properties. The use of a single symbol to denote this number 3.14159 . . . seems to have been introduced about the beginning of the eighteenth century. W. Jones* in 1706 represented it by π; a few years later† John Bernoulli denoted it by c; Euler in 1734 used p, and in 1736 used c; Chr. Goldback in 1742 used π; and after the publication of Euler's Analysis the symbol π was generally employed. The numerical value of π can be determined by either of two methods with as close an approximation to the truth as is desired. The first of these methods is geometrical. It consists in calculating the perimeters of polygons inscribed in and circumscribed about a circle, and assuming that the circumference of the circle is intermediate between these perimeters‡ . The approximation would be closer if the areas and not the perimeters were employed. The second and modern method rests on the determination of converging infinite series for π. We may say that the π-calculators who used the first method regarded π as equivalent to a geometrical ratio, but those who adopted the modern method treated it as the symbol for a certain number which enters into numerous branches of mathematical analysis. It may be interesting if I add here a list of some of the approximations to the value of π given by various writers§ . This will indicate * Synopsis Palmariorum Matheseos, London, 1706, pp. 243, 263 et seq. † See notes by G. Eneström in the Bibliotheca Mathematica, Stockholm, 1889, vol. iii, p. 28; Ibid., 1890, vol. iv, p. 22. ‡ The history of this method has been written by K.E.I. Selander, Historik öfver Ludolphska Talet, Upsala, 1868. § For the methods used in classical times and the results obtained, see the notices 214 THREE GEOMETRICAL PROBLEMS. [CH. VIII incidentally those who have studied the subject to the best advantage. The ancient Egyptians* took 256/81 as the value of π, this is equal to 3.1605 . . . ; but the rougher approximation of 3 was used by the Babylonians† and by the Jews‡ . It is not unlikely that these numbers were obtained empirically. We come next to a long roll of Greek

mathematicians who attacked the problem. Whether the researches of the members of the Ionian School, the Pythagoreans, Anaxagoras, Hippias, Antipho, and Bryso led to numerical approximations for the value of π is doubtful, and their investigations need not detain us. The quadrature of certain lunes by Hippocrates of Chios is ingenious and correct, but a value of π cannot be thence deduced; and it seems likely that the later members of the Athenian School concentrated their efforts on other questions. It is probable that Euclid§ , the illustrious founder of the Alexandrian School, was aware that π was greater than 3 and less than 4, but he did not state the result explicitly. The mathematical treatment of the subject began with Archimedes, who proved that π is less than 3 1 7 and greater than 3 10 71 , that is, it lies between 3.1428 . . . and 3.1408 . . . . He established‖ this by inscribing in a circle and circumscribing about it regular polygons of 96 sides, then determining by geometry the perimeters of these polygons, and finally assuming that the circumference of the circle was intermediate between these perimeters: this leads to the result 6336/2017 1 4 < π < 14688/4673 1 2 , 1 from which he deduced the limof their authors in M. Cantor's Geschichte der Mathematik, Leipzig, vol. i, 1880. For medieval and modern approximations, see the article by A. De Morgan on the Quadrature of the Circle in vol. xix of the Penny Cyclopaedia, London, 1841; with the additions given by B. de Haan in the Verhandelingen of Amsterdam, 1858, vol. iv, p. 22: the conclusions were tabulated, corrected, and extended by Dr J.W.L. Glaisher in the Messenger of Mathematics, Cambridge, 1873, vol. ii, pp. 119–128; and Ibid., 1874, vol. iii, pp. 27–46. * Ein mathematisches Handbuch der alten Aegypter (i.e. the Rhind papyrus), by A. Eisenlohr, Leipzig, 1877, arts. 100–109, 117, 124. † Oppert, Journal Asiatique, August, 1872, and October, 1874. ‡ 1 Kings, ch. 7, ver. 23; 2 Chronicles, ch. 4, ver. 2. § These results can be deduced from Euc. iv, 15, and iv, 8: see also book xii, prop. 16. ‖ Archimedis Opera, KÔκλου μὲτρησις, prop. iii, ed. Torelli, Oxford, 1792, pp. 205– 216; ed. Heiberg, Leipzig, 1880, vol. i, pp. 263-271. 1. Inserted 14688/ CH. VIII] APPROXIMATIONS TO THE VALUE OF π. 215 its given above. This method is equivalent to using the proposition sin θ < θ < tan θ, where θ = π/96: the values of sin θ and tan θ were deduced by Archimedes from those of sin 1 3 π and tan 1 3 π by repeated bisections of the angle. With a polygon of n sides this process gives a value of π correct to at least the integral part of (2 log n−1.19) places of decimals. The result given by Archimedes is correct to 2 places of decimals. His analysis leads to the conclusion that the perimeters of these polygons for a circle whose diameter is 4970 feet would lie between 15610 feet and 15620 feet—actually it is about 15613 feet 9 inches. Apollonius discussed these results, but his criticisms have been lost. Hero of Alexandria gave* the value 3, but he quoted† the result 22/7: possibly the former number was intended only for rough approximations. The only other Greek approximation that I need mention is that given by Ptolemy‡ , who asserted that π = 3◦8 '30''. This is equivalent to taking π = 3 + 8 60 + 30

3600 = 3 17 120 = 3.1416˙ . The Roman surveyors seem to have used 3, or sometimes 4, for rough calculations. For closer approximations they often employed 3 1 8 instead of 3 1 7 , since the fractions then introduced are more convenient in duodecimal arithmetic. On the other hand Gerbert§ recommended the use of 22/7. Before coming to the medieval and modern European mathematicians it may be convenient to note the results arrived at in India and the East. Baudhayana‖ took 49/16 as the value of π. Arya-Bhata¶ , circ. 530, gave 62832/20000, which is equal to 3.1416. He showed that, if a is the side of a regular polygon of n sides inscribed in a circle of unit diameter, and if b is the side of a regular inscribed polygon of 2n sides, then b 2 = 1 2 − 1 2 (1 − a 2) 1 2 . From the side of an inscribed hexagon, he found successively the sides of polygons of 12, 24, 48, 96, 192, and 384 sides. The perimeter of the last is given as equal to √ 9.8694, from which his result was obtained by approximation. * Mensurae, ed. Hultsch, Berlin, 1864, p. 188. † Geometria, ed. Hultsch, Berlin, 1864, pp. 115, 136. ‡ Almagest, bk. vi, chap. 7; ed. Halma, vol. i, p. 421. § Œuvres de Gerbert, ed. Olleris, Clermont, 1867, p. 453. ‖ The Sulvasutras by G. Thibaut, Asiatic Society of Bengal, 1875, arts. 26–28. ¶ Leçons de calcul d'Aryabhata, by L. Rodet in the Journal Asiatique, 1879, series 7, vol. xiii, pp. 10, 21. 216 THREE GEOMETRICAL PROBLEMS. [CH. VIII Brahmagupta* , circ. 650, gave √ 10, which is equal to 3.1622 . . . . He is said to have obtained this value by inscribing in a circle of unit diameter regular polygons of 12, 24, 48, and 96 sides, and calculating successively their perimeters, which he found to be √ 9.65, √ √ 9.81, 9.86, √ 9.87 respectively; and to have assumed that as the number of sides is increased indefinitely the perimeter would approximate to √ 10. Bhaskara, circ. 1150, gave two approximations. One†—possibly copied from Arya-Bhata, but said to have been calculated afresh by Archimedes's method from the perimeters of regular polygons of 384 sides—is 3927/1250, which is equal to 3.1416: the other‡ is 754 240 , which is equal to 3.1416˙ , but it is uncertain whether this was not given only as an approximate value. Among the Arabs the values 22/7, √ 10, and 62832/20000 were given by Alkarisimi§ , circ. 830; and no doubt were derived from Indian sources. He described the first as an approximate value, the second as used by geometricians, and the third as used by astronomers. In Chinese works the values 3, 22 7 , 157 50 are said to occur: probably the last two results were copied from the Arabs. Returning to European mathematicians, we have the following successive approximations to the value of π: many of those prior to the eighteenth century having been calculated originally with the view of demonstrating the incorrectness of some alleged quadrature. Leonardo of Pisa‖ , in the thirteenth century, gave for π the value 1440/458 1 3 which is equal to 3.1418 . . . . In the fifteenth century, Purbach¶ gave or quoted the value 62832/20000, which is equal to 3.1416˙ ; Cusa believed that the accurate value was 3 4 (√ 3 + √ 6) which is equal to 3.1423 . . . ; and, in 1464, Regiomontanus** is said to have given a value equal to

3.14243. * Algebra. . . from Brahmegupta and Bhascara, trans. by H.T. Colebrooke, London, 1817, chap. xii, art. 40, p. 308. † Ibid., p. 87. ‡ Ibid., p. 95. § The Algebra of Mohammed ben Musa, ed. by F. Rosen, London, 1831, pp. 71–72. ‖ Boncompagni's Scritti di Leonardo, vol. ii (Practica Geometriae), Rome, 1862, p. 90. ¶ Appendix to the De Triangulis of Regiomontanus, Basle, 1541, p. 131. ** In his correspondence with Cardinal Cusa, De Quadratura Circuli, Nuremberg, 1533, wherein he proved that Cusa's result was wrong. I cannot quote the exact reference, but the figures are given by competent writers and I have no doubt are correct. CH. VIII] APPROXIMATIONS TO THE VALUE OF π. 217 Vieta* , in 1579, showed that π was greater than 31415926535/1010 , and less than 31415926537/1010. This was deduced from the perimeters of the inscribed and circumscribed polygons of 6 × 2 16 sides, obtained by repeated use of the formula 2 sin2 1 2 θ = 1 − cos θ. He also gave† a result equivalent to the formula 2 π = √ 2 2 √ (2 + √ 2) 2 √ {2 + √ (2 + √ 2)} 2 · · · . The father of Adrian Metius‡ , in 1585, gave 355/113, which is equal to 3.14159292 . . . , and is correct to 6 places of decimals. This was a curious and lucky guess, for all that he proved was that π was intermediate between 377/120 and 333/106, whereon he jumped to the conclusion that he should obtain the true fractional value by taking the mean of the numerators and the mean of the denominators of these fractions. In 1593 Adrian Romanus§ calculated the perimeter of the inscribed regular polygon of 1073, 741824 (i.e. 2 30) sides, from which he determined the value of π correct to 15 places of decimals. L. van Ceulen devoted no inconsiderable part of his life to the subject. In 1596‖ he gave the result to 20 places of decimals: this was calculated by finding the perimeters of the inscribed and circumscribed regular polygons of 60 × 2 33 sides, obtained by the repeated use of a theorem of his discovery equivalent to the formula 1−cos A = 2 sin2 1 2A. I possess a finely executed engraving of him of this date, with the result printed round a circle which is below his portrait. He died in 1610, and by his directions the result to 35 places of decimals (which was as far as he had then calculated it) was engraved on his tombstone¶ in St Peter's Church, Leyden. His posthumous arithmetic** contains the result to 32 places; this was obtained by calculating the perimeter of a polygon, the * Canon Mathematicus seu ad Triangula, Paris, 1579, pp. 56, 66: probably this work was printed for private circulation only, it is very rare. † Vietae Opera, ed. Schooten, Leyden, 1646, p. 400. ‡ Arithmeticae libri duo et Geometriae, by A. Metius, Leyden, 1626, pp. 88, 89. [Probably issued originally in 1611.] § Ideae Mathematicae, Antwerp, 1593: a rare work, which I have never been able to consult. ‖ Vanden Circkel, Delf, 1596, fol. 14, p. 1; or De Circulo, Leyden, 1619, p. 3. ¶ The inscription is quoted by Prof. de Haan in the Messenger of Mathematics, 1874, vol. iii, p. 25. ** De Arithmetische en Geometrische Fondamenten, Leyden, 1615, p. 163; or p. 144 of the Latin translation by W. Snell, published at Leyden in 1615 under the 218 THREE GEOMETRICAL PROBLEMS. [CH. VIII number of whose

sides is 2 62 , i.e. 4, 611686, 018427, 387904. Van Ceulen also compiled a table of the perimeters of various regular polygons. Willebrord Snell* , in 1621, obtained from a polygon of 2 30 sides an approximation to 34 places of decimals. This is less than the numbers given by van Ceulen, but Snell's method was so superior that he obtained his 34 places by the use of a polygon from which van Ceulen had obtained only 14 (or perhaps 16) places. Similarly, Snell obtained from a hexagon an approximation as correct as that for which Archimedes had required a polygon of 96 sides, while from a polygon of 96 sides he determined the value of π correct to seven decimal places instead of the two places obtained by Archimedes. The reason is that Archimedes, having calculated the lengths of the sides of inscribed and circumscribed regular polygons of n sides, assumed that the length of 1/nth of the perimeter of the circle was intermediate between them; whereas Snell constructed from the sides of these polygons two other lines which gave closer limits for the corresponding arc. His method depends on the theorem 3 sin θ/(2 + cos θ) < θ < (2 sin 1 3 θ + tan 1 3 θ), by the aid of which a polygon of n sides gives a value of π correct to at least the integral part of (4 log n − .2305) places of decimals, which is more than twice the number given by the older rule. Snell's proof of his theorem is incorrect, though the result is true. Snell also added a table† of the perimeters of all regular inscribed and circumscribed polygons, the number of whose sides is 10×2 n where n is not greater than 19 and not less than 3. Most of these were quoted from van Ceulen, but some were recalculated. This list has proved useful in refuting circle-squarers. A similar list was given by James Gregory‡ . In 1630 Grienberger§ , by the aid of Snell's theorem, carried the approximation to 39 places of decimals. He was the last mathematician who adopted the classical method of finding the perimeters of inscribed and circumscribed polygons. Closer approximations serve no useful title Fundamenta Arithmetica et Geometrica. This was reissued, together with a Latin translation of the Vanden Circkel, in 1619, under the title De Circulo; in which see pp. 3, 29–32, 92. * Cyclometricus, Leyden, 1621, p. 55. † It is quoted by Montucla, ed. 1831, p. 70. ‡ Vera Circuli et Hyperbolae Quadratura, prop. 29, quoted by Huygens, Opera Varia, Leyden, 1724, p. 447. § Elementa Trigonometrica, Rome, 1630, end of preface. CH. VIII] APPROXIMATIONS TO THE VALUE OF π. 219 purpose. Proofs of the theorems used by Snell and other calculators in applying this method were given by Huygens in a work* which may be taken as closing the history of this method. In 1656 Wallis† proved that π 2 = 2 · 2 · 4 · 4 · 6 · 6 · · · 1 · 3 · 3 · 5 · 5 · 7 · 7 · · · , and quoted a proposition given a few years earlier by Viscount Brouncker to the effect that π 4 = 1 + 1 2 2 + 3 2 2 + 5 2 2 + . . . , but neither of these theorems was used to any large extent for calculation. Subsequent calculators have relied on converging infinite series, a method that was hardly practicable prior to the invention of the calculus, though Descartes‡ had indicated a geometrical process which was equivalent to the use of such a series. The

employment of infinite series was proposed by James Gregory§ , who established the theorem that θ = tan θ − 1 3 tan3 θ + 1 5 tan5 θ − · · · , the result being true only if θ lies between − 1 4 π and 1 4 π. The first mathematician to make use of Gregory's series for obtaining an approximation to the value of π was Abraham Sharp‖ , who, in 1699, on the suggestion of Halley, determined it to 72 places of * De Circula Magnitudine Inventa, 1654; Opera Varia, pp. 351–387. The proofs are given in G. Pirie's Geometrical Methods of Approximating the Value of π, London, 1877, pp. 21–23. † Arithmetica Infinitorum, Oxford, 1656, prop. 191. An analysis of the investigation by Wallis was given by Cayley, Quarterly Journal of mathematics, 1889, vol. xxiii, pp. 165–169. ‡ See Euler's paper in the Novi Commentarii Academiae Scientiarum, St Petersburg, 1763, vol. viii, pp. 157–168. § See the letter to Collins, dated Feb. 15, 1671, printed in the Commercium Epistolicum, London, 1712, p. 25, and in the Macclesfield Collection, Correspondence of Scientific Men of the Seventeenth Century, Oxford, 1841, vol. ii, p. 216. ‖ See Life of A. Sharp by W. Cudworth, London, 1889, p. 170. Sharp's work is given in one of the preliminary discourses (p. 53 et seq.) prefixed to H. Sherwin's Mathematical Tables. The tables were issued at London in 1705: probably the discourses were issued at the same time, though the earliest copies I have seen were printed in 1717. 220 THREE GEOMETRICAL PROBLEMS. [CH. VIII decimals (71 correct). He obtained this value by putting θ = 1 6 π in Gregory's series. Machin* , earlier than 1706, gave the result to 100 places (all correct). He calculated it by the formula 1 4 π = 4 tan−1 1 5 − tan−1 1 239 . De Lagny† , in 1719, gave the result to 127 places of decimals (112 correct), calculating it by putting θ = 1 6 π in Gregory's series. Hutton‡ , in 1776, and Euler§ , in 1779, suggested the use of the formulae 1 4 π = tan−1 1 2 + tan−1 1 3 or 1 4 π = 5 tan−1 1 7 + 2 tan−1 3 79 , but neither carried the approximation as far as had been done previously. Vega, in 1789‖ , gave the value of π to 143 places of decimals (126 correct); and, in 1794¶ , to 140 places (136 correct). Towards the end of the last century Baron Zach saw in the Radcliffe Library, Oxford, a manuscript by an unknown author which gives the value of π to 154 places of decimals (152 correct). In 1841 Rutherford** calculated it to 208 places of decimals (152 correct), using the formula 1 4 π = 4 tan−1 1 5 − tan−1 1 70 + tan−1 1 99 . In 1844 Dase†† calculated it to 205 places of decimals (200 correct), using the formula 1 4 π = tan−1 1 2 + tan−1 1 5 + tan−1 1 8 . In 1847 Clausen‡‡ carried the approximation to 250 places of decimals (248 correct), calculating it independently by the formulae 1 4 π = 2 tan−1 1 3 + tan−1 1 7 and 1 4 π = 4 tan−1 1 5 − tan−1 1 239 . In 1853 Rutherford§§ carried his former approximation to 440 places of decimals (all correct), and William Shanks prolonged the approximation to 530 places. In the same year Shanks published an approximation * W. Jones's Synopsis Palmariorum, London, 1706, p. 243; and Maseres, Scriptores Logarithmici, London, 1796, vol. iii, pp. vii–ix, 155–164. † Histoire de l'Académie for 1719,

CH. VIII] APPROXIMATIONS TO THE VALUE OF π. 221 to 607 places* : and in 1873 he carried the approximation to 707 places of decimals† . These were calculated from Machin's formula. In 1853 Richter, presumably in ignorance of what had been done in England, found the value of π to 333 places‡ of decimals (330 correct); in 1854 he carried the approximation to 400 places§ ; and in 1855 carried it to 500 places‖ . Of the series and formulae by which these approximations have been calculated, those used by Machin and Dase are perhaps the easiest to employ. Other series which converge rapidly are the following, π 6 = 1 2 + 1 2 · 1 3 · 2 3 + 1 · 3 2 · 4 · 1 5 · 2 5 + · · · , and π 4 = 2 + 22 tan−1 1 28 + tan−1 1 443 − 5 tan−1 1 1393 − 10 tan−1 1 11018 , the latter of these is due to Mr Escott¶ . As to those writers who believe that they have squared the circle their number is legion and, in most cases, their ignorance profound, but their attempts are not worth discussing here. "Only prove to me that it is impossible," said one of them, "and I will set about it immediately"; and doubtless the statement that the problem is insoluble has attracted much attention to it. Among the geometrical ways of approximating to the truth the following is one of the simplest. Inscribe in the given circle a square, and to three times the diameter of the circle add a fifth of a side of the square, the result will differ from the circumference of the circle by less than one-seventeen-thousandth part of it. An approximate value of π has been obtained experimentally by the theory of probability. On a plane a number of equidistant parallel straight lines, distance apart a, are ruled; and a stick of length l, which * Contributions to Mathematics, W. Shanks, London, 1853, pp. 86, 87. † Proceedings of the Royal Society, 1872–3, vol. xxi, p. 318; 1873–4, vol. xxii, p. 45. ‡ Grunert's Archiv, vol. xxi, p. 119. § Ibid., vol. xxiii, p. 476: the approximation given in vol. xxii, p. 473, is correct only to 330 places. ‖ Ibid., vol. xxv, p. 472; and Elbingen Anzeigen, No. 85. ¶ L'Intermédiaire des mathématiciens, Paris, Dec. 1896, vol. iii, p. 276. 222 THREE GEOMETRICAL PROBLEMS. [CH. VIII is less than a, is dropped on to the plane. The probability that it will fall so as to lie across one of the lines is 2l/πa. If the experiment is repeated many hundreds of times, the ratio of the number of favourable cases to the whole number of experiments will be very nearly equal to this fraction: hence the value of π can be found. In 1855 Mr A. Smith* of Aberdeen made 3204 trials, and deduced π = 3.1553. A pupil of Prof. De Morgan* , from 600 trials, deduced π = 3.137. In 1864 Captain

Fox† made 1120 trials with some additional precautions, and obtained as the mean value π = 3.1419. Other similar methods of approximating to the value of π have been indicated. For instance, it is known that if two numbers are written down at random, the probability that they will be prime to each other is 6/π2 . Thus, in one case‡ where each of 50 students wrote down 5 pairs of numbers at random, 154 of the pairs were found to consist of numbers prime to each other. This gives 6/π2 = 154/250, from which we get π = 3.12. * A. De Morgan, Budget of Paradoxes, London, 1872, pp. 171, 172 [quoted from an article by De Morgan published in 1861]. † Messenger of Mathematics, Cambridge, 1873, vol. ii, pp. 113, 114. ‡ Note on π by R. Chartres. Philosophical Magazine, London, series 6, vol. xxxix, March, 1904, p. 315. CHAPTER IX. MERSENNE'S NUMBERS. One of the unsolved riddles of higher arithmetic, to which I have alluded in Chapter I, is the discovery of the method by which Mersenne or his contemporaries determined values of p which make a number of the form 2 p − 1 a prime. It is convenient to describe such primes as Mersenne's Numbers. In this chapter, for shortness, I use N to denote a number of the form 2 p − 1. In a memoir in the Messenger of Mathematics in 1891 I gave a brief sketch of the history of the problem. I here repeat the facts in somewhat more detail, and add a sketch of methods used in attacking the problem. Mersenne's enunciation of the results associated with his name is in the preface to his Cogitata† . The passage is as follows: "Vbi fuerit operae pretium aduertere xxviii numeros a Petro Bungo pro perfectis exhibitos, capite xxviii, libri de Numeris, non esse omnes Perfectos, quippe 20 sunt imperfecti, adeovt [adeunt?] solos octo perfectos habeat. . . qui sunt è regione tabulae Bungi, 1, 2, 3, 4, 8, 10, 12, et 29: quique soli perfecti sunt, vt qui Bungum habuerint, errori medicinam faciant. Porrò numeri perfecti adeo rari sunt, vt vndecim dumtaxat potuerint hactenus inueniri: hoc est, alii tres a Bongianis differentes: neque enim vllus est alius perfectus ab illis octo, nisi superes exponentem numerum 62, progressionis duplae ab 1 incipientis. Nonus enim perfectus est potestas exponentis 68 minus 1. Decimus, potestas exponentis 128, minus 1. Vndecimus denique, potestas 258, minus 1, hoc est potestas 257, vnitate decurtata, multiplicata per potestatem 256. Qui vndecim alios repererit, nouerit se analysim omnem, quae fuerit hactenus, superasse: memineritque interea nullum esse perfectum à 17000 † Cogitata Physico-Mathematica, Paris, 1644, praefatio generalis, article 19. 223 224 MERSENNE'S NUMBERS. [CH. IX potestate ad 32000; & nullum potestatum interuallum tantum assignari posse, quin detur illud absque perfectis. Verbi gratia, si fuerit exponens 1050000, nullus erit numerus progressionis duplae vsque ad 2090000, qui perfectis numeris seruiat, hoc est qui minor vnitate, primus existat. Vnde clarum est quàm rari sint perfecti numeri, & quàm merito viris perfectis comparentur; esseque vnam ex maximis totius Matheseos difficultatibus, praescriptam numerorum perfectorum multitudinum exhibere; quemadmodum & agnoscere num dati numeri 15, aut 20 caracteribus

constantes, sint primi necne, cùm nequidem saeculum integrum huic examini, quocumque modo hactenus cognito, sufficiat. It is evident that, if p is not a prime, then N is composite, and two or more of its factors can be written down by inspection. Hence we may confine ourselves to prime values of p. Mersenne, in effect, asserted that the only values of p, not greater than 257, which make N a prime, are 1, 2, 3, 5, 7, 13, 17, 19, 31, 67, 127, 257: I assume that the number 67 is a misprint for 61. With this correction we have no reason to doubt the truth of the statement, but it has not been definitely established. There are 56 primes not greater than 257. The determination of the prime or composite character of N for the 9 cases when p is less than 20 presents no difficulty: in only one of them is N composite. For 2 of the remaining 47 cases (namely, when p = 23 and 37) the decomposition of N had been given by Fermat. For 9 of them (namely, when p = 29, 43, 73, 83, 131, 179, 191, 239, 251) the factors of N were given by Euler. He also proved that N was prime when p = 31. Plana gave the factors of N when p = 41. Landry and Le Lasseur discovered the factors in 10 cases (namely, when p = 47, 53, 59, 79, 97, 113, 151, 211, 223, and 233), but their analysis has not been published. Seelhoff showed that N was prime when p = 61, Cunningham gave the factors when p = 197, and Cole the factors when p = 67. Statements have been made that the composite character of N when p = 89, and its prime character when p = 127 have been proved, but the proofs have not been published or verified. Thus there are 21 values of p for which Mersenne's statement still awaits verification. These are 71, 89, 101, 103, 107, 109, 127, 137, 139, 149, 157, 163, 167, 173, 181, 193, 199, 227, 229, 241, 257. For these values N is (according to Mersenne) prime when p = 127, and 257, and is composite for the other values, but as explained above it is probable that the character of N is known when p = 89 and 127. To put the matter in another way. According to Mersenne's statement (corrected by the substitution of 61 for 67), 44 of the 56 primes CH. IX] MERSENNE'S NUMBERS. 225 less than 258 make N composite and the remaining 12 primes make N prime. In 25 out of the 44 cases in which N is said to be composite we know its factors, and in 19 cases the statement is still unverified. In 10 out of the 12 cases in which he said that N was prime his statement has been verified, and in 2 cases it is still unverified. From the wording of the last clause in the above quotation it has been conjectured that the result had been communicated to Mersenne, and that he published it without being aware of how it was proved. In itself this seems probable. He was a good mathematician, but not an exceptional genius. It would be strange if he established a proposition which has baffled Euler, Lagrange, Legendre, Gauss, Jacobi, and other mathematicians of the first rank; but if the proposition is due to Fermat, with whom Mersenne was in constant correspondence, the case is altered, and not only is the absence of a demonstration explained, but we cannot be sure that we have attacked the problem on the best lines. The known results as to the

prime or composite character of N, and in the latter case its smallest factor, are given in the table on the following page. The cases that remain as yet unverified are marked with an asterisk. Before describing the methods used for attacking the problem it will be convenient to state in more detail when and by whom these results were established. The factors (if any) of such values of N as are less than a million can be verified easily: they have been known for a long time, and I need not allude to them in detail. The factors of N when p = 11, 23, and 37 had been indicated by Fermat* , some four years prior to the publication of Mersenne's work, in a letter dated October 18, 1640. The passage is as follows: En la progression double, si d'un nombre quarré, généralement parlant, vous ôtez 2 ou 8 ou 32 &c., les nombres premiers moindres de l'unite qu'un multiple du quaternaire, qui mesureront le reste, feront l'effet requis. Comme de 25, qui est un quarré, ôtez 2; le reste 23 mesurera la 11e puissance −1; ôtez 2 de 49, le reste 47 mesurera la 23e puissance −1. Ôtez 2 de 225, le reste 223 mesurera la 37e puissance −1, &c. The factors of N when p = 29, 43, and 73 were given by Euler† * Oeuvres de Fermat, Paris, vol. ii, 1894, p. 210; or Opera Mathematica, Toulouse, 1679, p. 164; or Brassinne's Précis, Paris, 1853, p. 144. † Commentarii Academiae Scientiarum Petropolitanae, 1738, vol. vi, p. 103; or Commentationes Arithmeticae Collectae, vol. i, p. 2. 226 MERSENNE'S NUMBERS. The fact that N is composite for the values p = 83, 131, 179, 191, 239, and 251 follows from a proposition enunciated, at the same time, by Euler to the effect that, if 4n + 3 and 8n + 7 are primes, then 2 4n+3 − 1 ≡ 0 (mod 8n + 7). This was proved by Lagrange* in his classical memoir of 1775. The proposition also covers the cases of p = 11 and p = 23. This is the only general theorem on the subject which is yet established. The fact that N is prime when p = 31 was proved by Euler† in 1771. Fermat had asserted, in the letter mentioned above, that the only possible prime factors of 2 p ± 1, when p was prime, were of the form np + 1, where n is an integer. This was proved by Euler‡ in 1748, who added that, since 2 p ± 1 is odd, every factor of it must be odd, and therefore if p is odd n must be even. But if p is a given number we can define n much more closely, and Euler showed that the prime factors (if any) of 2 31 − 1 were necessarily primes of the form 248n + 1 or 248n+ 63; also they must be less than √ 2 31 − 1, that is, than 46339. * Nouveaux Mémoires de l'Académie des Sciences de Berlin, 1775, pp. 323–356. † Histoire de l'Académie des Sciences for 1772, Berlin, 1774, p. 36. See also Legendre, Théorie des Nombres, third edition, Paris, 1830, vol. i, pp. 222–229. ‡ Novi Commentarii Academiae Scientiarum Petropolitanae, vol. i, p. 20; or Commentationes Arithmeticae Collectae, St Petersburg, 1849, vol. i, pp. 55, 56. 228 MERSENNE'S NUMBERS. [CH. IX Hence it is necessary to try only forty divisors to see if 2 31 − 1 is a prime or composite. The factors of N when p = 41 were given by Plana* in 1859. He showed that the prime factors (if any) are primes of the form 328n+1 or 328n+247, and lie between 1231 and √ 2 41 − 1, that is, 1048573. Hence it is necessary to try only 513 divisors to see if 2 41 − 1 is composite: the seventeenth of these divisors gives the required factors. This is the same method of attacking the problem which was used by Euler in 1771, but it would be very laborious to employ it for values of p greater than 41. Plana† added the forms of the prime divisors of N, if p is not greater than 101. That N is prime when p = 127 seems to have been verified by Lucas‡ in 1876 and 1877. The demonstration has not been published. The discovery of the factors of N for the values p = 47, 53, and 59 is due apparently to the late F. Landry, who established theorems on the factors (if any) of numbers of certain forms. Instead of publishing his results he issued a challenge to all mathematicians to solve the general problem. This is contained in a rare pamphlet published at Paris in 1867, of which I possess a copy, in which the factors of certain numbers are given, and on page 8 of which it is implied that he had obtained

the factors of 2 p − 1 when p = 47, 53, and 59. He seems to have communicated his results to Lucas, who quoted them in the memoir cited below§ . The factors of N when p = 79 and 113 were given first by Le Lasseur, and were quoted by Lucas in the same memoir§ . A factor of N when p = 233 was discovered later by Le Lasseur, and was quoted by Lucas in 1882‖ . The factors of N when p = 97, 151, 211, and 223 were determined subsequently by Le Lasseur, and were quoted by Lucas¶ in 1883. * G.A.A. Plana, Memorie della Reale Accademia delle Scienze di Torino, Series 2, vol. xx, 1863, p. 130. † Ibid., p. 137. ‡ Sur la Théorie des Nombres Premiers, Turin, 1876, p. 11; and Recherches sur les Ouvrages de Léonard de Pise, Rome, 1877, p. 26, quoted by Lieut.-Colonel A.J.C. CH. IX] MERSENNE'S NUMBERS. 229 That N is prime when p = 61 had been conjectured by Landry and in 1886 a demonstration was offered by Seelhoff* . His demonstration is open to criticism, but the fact has been verified by others† , and may be accepted as proved. That N is composite when p = 89 seems to have been verified by Lucas‡ in 1891, but the demonstration has not been published, nor have the actual factors been discovered. That 7487 is a factor of N when p = 197 was shown by A.J.C. Cunningham in 1895§ . That N is not prime when p = 67 seems to have been verified by Lucas‖ in 1876 and 1877. The composite nature of1 N = 2p − 1 when p = 67 was confirmed by E. Fauquembergue¶ , and was also implied by Lucas** in 1891. The factors were given by F.N. Cole†† in 1903. Bickmore in the memoir‡‡ cited below showed that 1433 is another factor of N if p = 179; and that 1913 and 5737 are other factors of N if p = 239. I turn next to consider the methods by which these results can be obtained. It is impossible to believe that the statement made by Mersenne rested on an empirical conjecture, but the riddle as to how it was discovered is still, after nearly 250 years, unsolved. I cannot offer any solution of the riddle. But it may be interesting to indicate some ways which have been used in attacking the problem. * P.H.H. Bickmore, Messenger of Mathematics, Cambridge, 1895, vol. xxv, p. 19. 1. Corrected:

originally N 2 p = 1 230 MERSENNE'S NUMBERS. [CH. IX The object is to find a prime divisor q (other than N and 1) of a number N when N is of the form 2 p−1 and p is a prime. It can be easily shown that q must be of the form 2pt + 1. Also q must be of one of the forms 8i ± 1: for N is of the form 2A2 − B2 , where A is even and B odd, hence* any factor of it must be of the form 2a 2 −b 2 , that is, of the form 8i±1, and 2 must be a quadratic residue of q. The theory of residues is, however, of but little use in finding factors of the cases that still await solution, though the possibility some day of finding a complete series of solutions by properties of residues must not be neglected† . Our present knowledge of the means of factorizing N has been summed up in the statement‡ that a prime factor of the form 2pt+1 can be found directly by rules due to Legendre, Gauss, and Jacobi, when t = 1, 3, 4, 8, or 12; and that a factor of the form 2ptt' + 1 can be found indirectly by a method due to Bickmore when t = 1, 3, 4, 8, or 12, and t ' is an odd integer greater than 3. But this only indicates how little has yet been done towards finding a general solution of the problem. First. There is the simple but crude method of trying all possible prime divisors q which are of the form 2pt + 1 as well as of one of the forms 8i ± 1. The chief known results for the smaller factors may be summarized by saying that a prime of this form will divide N when t = 1, if p = 11, 23, 83, 131, 179, 191, 239, or 251; when t = 3, if p = 37, 73, or 233; when t = 5, if p = 43; when t = 15, if p = 113; when t = 17, if p = 79; when t = 19, if p = 29, or 197; when t = 25, if p = 47; when t = 41, if p = 223; when t = 59, if p = 97; when t = 163, if p = 41; when t = 1525, if p = 59; when t = 4, if p = 11, 29, 179, or 239; when t = 8, if p = 11; when t = 12, if p = 239; when t = 36, if p = 29, or 211; when t = 60, if p = 53, or 151; and when t = 1445580, if p = 67. Of the 25 cases in which we know that Mersenne's statement of the composite character of N is correct all save 3 can be easily verified by trial in this way. For neglecting all values of t not exceeding, say, * Legendre, Théorie des Nombres, third edition, Paris, 1830, vol. i, § 143. In the case of Mersenne's numbers, B = b = 1. † For methods of finding the residue indices of 2 see Bickmore, Messenger of Mathematics, May, 1895, vol. xxv, pp. 15–21; see also Lieut-Colonel A.J.C. Cunningham on 2 as a 16-ic residue, Proceedings of the London Mathematical Society, 1895–6, vol. xxvii, pp. 85–122. ‡ Transactions of the British Association for the Advancement of Science (Ipswich Meeting), 1895, p. 614. CH. IX] MERSENNE'S NUMBERS. 231 60 which make q either composite or not of one of the forms 8i ± 1 we have in each case only some 20 or so divisors to try. Of the 3 other cases in which Mersenne's statement of the composite character of N has been verified, one verification (p = 41) is due to Plana, who frankly confessed that the result was reached "par un heureux hasard"; a second is due to Landry (p = 59), who did not explain how he obtained the factors; and the third is due to Cole (p = 67), who established it by the use of quadratic residues of N, involving laborious numerical work. Of the 10 cases in which we know that Mersenne's statement of the prime character of N is correct all save one

may be verified by trial in this way, for the number of possible factors is not large. The exception is the case where p equals 61, which Seelhoff and others have shown to be prime. Thus practically we may say that simple empirical trials would at once lead us to all the conclusions known except in the case of p = 41 due to Plana, of p = 59 due to Landry, of p = 61 due to Seelhoff, and of p = 67 due to Cole. In fact, save for these four results the conclusions of all mathematicians to date could be obtained by anyone by a few hours' arithmetical work. As p increases the number of factors to be tried increases so fast that, if p is large, it would be practically impossible to apply the test to obtain large factors. This is an important point, for it has been asserted that in the cases still awaiting verification there are no factors less than 50, 000. Hence, we may take it as reasonably certain that this cannot have been the method by which the result was originally obtained; nor, as here enunciated, is it likely to give many factors not yet known. Of course it is possible there may be ways by which the number of possible values of t might be further limited, and if we could find them we might thus diminish the number of possible factors to be tried, but it will be observed that the values of N which still await verification are very large, for instance, when p = 257, N contains no less than 78 digits. It is hardly necessary to add that if q is known and is not very large we can determine whether or not it is a factor of N without the labour of performing the division. For instance, if we want to verify that q = 13367 is a factor of N when p = 41, we proceed thus. Take the power of 2 nearest to q or to 232 MERSENNE'S NUMBERS. [CH. IX its square-root. We have to the modulus q 2 14 = 16384 ≡ 3017 ≡ 7 × 431 , ∴ 2 28 ≡ 49(−1377) ≡ −638 , ∴ 2 27 ≡ −319 , ∴ 2 14+27 ≡ (3017)(−319) ≡ 1 , ∴ 2 41 ≡ 1 . Second. We can proceed by reducing the problem to the solution of an indeterminate equation. It is clear that we can obtain a factor of N if we can express it as the difference of the squares, or more generally of the nth powers, of two integers u and v. Further, if we can express a multiple of N, say mN, in this form, we can find a factor of mN and (with certain obvious limitations as to the value of m) this will lead to a factor of N. It may be also added that if m can be found so that N/m is expressible as a continued fraction of a certain form, a certain continuant* defined by the form of the continued fraction is a factor of N. Since N can always be expressed as the difference of two squares, this method seems a natural one by which to attack the problem. If we put N = n 2 + a = (n + b) 2 − (b 2 + 2bn − a), we can make use of the known forms of u and v, and thus obtain an indeterminate equation between two variables x and y of the form x 2 = (2py + H) 2 − 4(K − y) where H and K are numbers which can be easily calculated. Integral values of x and y where y < K will determine values of u and v, and thus give factors of N. We can also attack the problem by indeterminate equations in an- * See J.G. Birch in the Messenger of Mathematics, August, 1902, vol. xxii, pp. 52– 55. CH. IX] MERSENNE'S NUMBERS. 233 other way. For the factors must be of the form 2pt+1 and 8ps+1, hence (2pt + 1)(8ps + 1) = N , = 2p − 1 ,

= 2(2p−1 − 1) + 1 , ∴ 4s + t + 8pst = (2p−1 − 1)/p , = (say)α + 8pβ . Hence 4s + t = α + 8px, and st = β − x , where x ≯ β and t is odd. These results again lead to an indeterminate equation. But, in both cases, unless p is small, the resulting equations are intractable. Third. A not uncommon method of attacking problems such as this, dealing with the factorization of large numbers, is through the theory of quadratic forms* . At best this is a difficult method to use, and we have no reason to think that it would have been employed by a mathematician of the seventeenth century. I here content myself with alluding to it. Fourth. There is yet another way in which the problem might be attacked. The problem will be solved if we can find an odd prime q so that to it as modulus 2 p+y ≡ z, and 2 y ≡ z, where y and z may have any values we like to choose. If such values of q, y, and z can be found, we have 2 y (2p − 1) ≡ 0. Therefore 2 p = 1, that is, q is a divisor of N. For example, to the modulus 23, we have 2 8 ≡ 3 , 2 16 ≡ 3 2 . Also 2 5 ≡ 3 2 . Therefore 2 16 − 2 5 ≡ 0 , ∴ 2 11 − 1 ≡ 0 . Without going further into the matter we may say that the à priori determination of the values q, y, and z introduces us to an almost * For a sketch of this see G.B. Mathews, Theory of Numbers, part 1, Cambridge, 1891, pp. 261-271. See also F.N. Cole's paper, On the Factoring of Large Numbers, Bulletin of the American Mathematical Society, December, 1903, pp. 134-137; and Quadratic Partitions by A.J.C. Cunningham, London, 1904. 234 MERSENNE'S NUMBERS. [CH. IX untrodden field. It is just possible (though I should suppose unlikely) that the key to the riddle is to be found on methods of finding q, y, z, to satisfy the above conditions. For instance, if we could say what was the remainder when 2 x was divided by a prime q of the form 2pt + 1, and if the remainders were the same when x = u and x = v, then to the modulus q we should have, 2 u ≡ 2 v , and therefore 2 u−v ≡ 1. It should however be noted that Jacobi's Canon Arithmeticus and the similar canon drawn up by Cunningham would, if carried far enough, enable us to solve the problem by this method. Cunningham's Canon gives the solution of the congruence 2 x ≡ R for all prime moduli less than 1000, but it is of no use in determining factors of N larger than 1000. It is however possible that if R or q have certain forms such a canon might be constructed, and thus lead to a solution of the problem. Fifth. It is noteworthy that the odd values of p specified by Mersenne are primes of one of the four forms 2 q ± 1 or 2 q ± 3, but it is not the case that all primes of these forms make N a prime, for instance, N is composite if p = 23 + 3 = 11 or if p = 25 − 3 = 29. This fact has suggested to more than one mathematician the possibility that some test as to the prime or composite character of N when p is of one of these forms may be discoverable. Of course this is merely a conjecture. There is however this to say for it, that we know that Fermat* had paid attention to numbers of this form. Sixth. The number N when expressed in the binary scale, consists of 1 repeated p times. This has suggested whether the work connected with the determination of factors of N might not with advantage be expressed in the binary scale. A method based on the use of

properties of this scale has been indicated by G. de Longchamps† , but as there given it would be unlikely to lead to the discovery of large divisors. I am, however, inclined to think that greater advantages would be gained by working in a scale whose radix was 4p or may-be 8p—the resulting numbers being then expressed by a reasonably small number of digits. In fact when expressed in the latter scale in only one out of the 25 cases in which the factors of N are known does the smallest factor contain more than two digits. * Ex. gr., see above, page 31. † Comptes rendus de l'Académie des Sciences, Paris, Nov. 1877, vol. lxxxv, pp. 950–952. CH. IX] MERSENNE'S NUMBERS. 235 Seventh. I have reserved to the last the description of the method which seems to me to be the most hopeful. We know by Fermat's Theorem that if x + 1 is a prime then 2 x − 1 is divisible by x + 1. Hence if 2pt + 1 is a prime we have, to the modulus 2pt + 1 2 2pt − 1 ≡ 0 , ∴ (2p − 1)(1 + 2p + 22p + · · · + 2(2t−1)p) ≡ 0 . Hence, a divisor of 2 p −1 will be known, if we can find a value of t such that 2pt + 1 is prime and the second factor is prime to it. This method may be used to establish Euler's theorem of 1732. For if we put t = 1, and if 2p+ 1 is a prime, we have, to the modulus 2p+ 1 (2p − 1)(2p + 1) ≡ 0 . Hence 2 p ≡ 1 if 2 p + 1 is prime to 2p+ 1. This is the case if p = 4m+ 3. Hence 2p + 1 is a factor of N if p = 11, 23, 83, 131, 179, 191, 239, and 251, for in these cases 2p + 1 is prime. The problem of Mersenne's Numbers is a particular case of the determination of the factors of a n −1. This has been the subject of investigations by many mathematicians: an outline of their conclusions has been given by Bickmore* . I ought also to add a reference to the general method suggested by F.W. Lawrence† for the factorization of any high number: it is possible that Fermat used some method analogous to this. Finally, I should add that machines‡ have been devised for investigating whether a number is prime, but I do not know that any have been constructed suitable for numbers as large as those involved in the numbers in question. * Messenger of Mathematics, Cambridge, 1895–6, vol. xxv, pp. 1–44; also 1896–7, vol. xxvi, pp. 1–38; see also a note by Mr E.B. Escott in the Messenger, 1903–4, vol. xxxiii, p. 49. † Ibid., 1894–5, vol. xxiv, pp. 100–109; Quarterly Journal of Mathematics, 1896, vol. xxviii, pp. 285–311; and Transactions of the London Mathematical Society, May 13, 1897, vol. xxviii, pp. 465–475. ‡ F.W. Lawrence, Quarterly Journal of Mathematics, 1896, already quoted, pp. 310–311; see also C.A. Laisant, Comptes Rendus Association Français pour l'avancement des sciences, 1891 (Marseilles), vol. xx, pp. 165–8. CHAPTER X. ASTROLOGY. Astrologers professed to be able to foretell the future, and within certain limits to control it. I propose to give in this chapter a concise account of the rules they used for this purpose† . I have not attempted to discuss the astrology of periods earlier than the middle ages, for the technical laws of the ancient astrology are not known with accuracy. At the same time there is no doubt that, as far back as we have any definite historical information, the art was practised in the East; that thence it was transplanted to

Egypt, Greece, and Rome; and that the medieval astrology was founded on it. It is probable that the rules did not differ materially from those described in this chapter‡ , and it may be added that the more intelligent thinkers of the old world recognised that the art had no valid pretences to accuracy. I may note also that the history of the development of the art ceases with the general acceptance of the Copernican theory, after which the practice of astrology rapidly became a mere cloak for imposture. † I have relied mainly on the Manual of Astrology by Raphael—whose real name was R.C. Smith—London, 1828, to which the references to Raphael hereafter given apply; and on Cardan's writings, especially his commentary on Ptolemy's work and his Geniturarum Exempla. I am indebted also for various references and gossip to Whewell's History of the Inductive Sciences; to various works by Raphael, published in London between 1825 and 1832; and to a pamphlet by M. Uhlemann, entitled Grundzüge der Astronomie und Astrologie, Leipzig, 1857. ‡ On the influences attributed to the planets, see The Dialogue of Bardesan on Fate, translated by W. Cureton in the Spicilegium Syriacum, London, 1855. 236 CH. X] ASTROLOGY. 237 All the rules of the medieval astrology—to which I confine myself— are based on the Ptolemaic astronomy, and originate in the Tetrabiblos * which is said, it may be falsely, to have been written by Ptolemy himself. The art was developed by numerous subsequent writers, especially by Albohazen† , and Firmicus. The last of these collected the works of most of his predecessors in a volume‡ , which remained a standard authority until the close of the sixteenth century. I may begin by reminding the reader that though there was a fairly general agreement as to the methods of procedure and interpretation— which alone I attempt to describe—yet there was no such thing as a fixed code of rules or a standard text-book. It is therefore difficult to reduce the rules to any precise and definite form, and almost impossible, within the limits of a chapter, to give detailed references. At the same time the practice of the elements of the art was tolerably well established and uniform, and I feel no doubt that my account, as far as it goes, is substantially correct. There were two distinct problems with which astrologers concerned themselves. One was the determination in general outline of the life and fortunes of an enquirer: this was known as natal astrology, and was effected by the erection of a scheme of nativity. The other was the means of answering any specific question about the individual: this was known as horary astrology. Both depended on the casting or erecting of a horoscope. The person for whom it was erected was known as the native. A horoscope was cast according to the following rules§ . The space between two concentric and similarly situated squares was divided into twelve spaces, as shown in the annexed diagram. These twelve spaces were known technically as houses; they were numbered consecutively 1, 2, . . . , 12 (see figure); and were described as the first house, the second house, and so on. The dividing lines were termed cusps: the line between the houses 12 and 1 was

called the cusp of the first house, the line between the houses 1 and 2 was called the cusp of the second house, and so on, finally the line between the houses 11 and 12 was called the cusp of the twelfth house. Each house had also a name of its * There is an English translation by J. Wilson, London [n.d.]; and a French translation is given in Halma's edition of Ptolemy's works. † De judiciis astrorum, ed. Liechtenstein, Basle, 1571. ‡ Astronomicorum, eight books, Venice, 1499. § Raphael, pp. 91–109. 238 ASTROLOGY. [CH. X 3 4 5 2 1 12 11 10 9 6 7 8 own—thus the first house was called the ascendant house, the eighth house was called the house of death, and so on—but as these names are immaterial for my purpose I shall not define them. Next, the positions which the various astrological signs and planets had occupied at some definite time and place (for instance, the time and place of birth of the native, if his nativity was being cast) were marked on the celestial sphere. This sphere was divided into twelve equal spaces by great circles drawn through the zenith, the angle between any two consecutive circles being 30◦ . The first circle was drawn through the East point, and the space between it and the next circle towards the North corresponded to the first house, and sometimes was called the first house. The next space, proceeding from East to North, corresponded to the second house, and so on. Each of the twelve spaces between these circles corresponded to one of the twelve houses, and each of the circles to one of the cusps. In delineating* a horoscope, it was usual to begin by inserting the zodiacal signs. A zodiacal sign extends over 30◦ , and was marked on the cusp which passed through it: by its side was written a number indicating the distance to which its influence extended in the earlier of the two houses divided by the cusp. Next the position of the planets in these signs were calculated, and each planet was marked in its proper * Raphael, pp. 118–131. CH. X] ASTROLOGY. 239 house and near the cusp belonging to the zodiacal sign in which the planet was then situated: it was followed by a number indicating its right ascension measured from the beginning of the sign. The name of the native and the date for which the horoscope was cast were inserted usually in the central square. The diagram near the end of this chapter is a facsimile of the horoscope of Edward VI as cast by Cardan and will serve as an illustration of the above remarks. We are now in a position to explain how a horoscope was read or interpreted. Each house was associated with certain definite questions and subjects, and the presence or absence in that house of the various signs and planets gave the answer to these questions or information on these subjects. These questions cover nearly every point on which information would be likely to be sought. They may be classified roughly as follows. For the answer, so far as it concerns the native, to all questions connected with his life and health, look in house 1; for questions connected with his wealth, refer to house 2; for his kindred and communications to him, refer to 3; for his parents and inheritances, refer to 4; for his children and amusements, refer to 5; for his servants and illnesses, refer to 6; for his

marriage and amours, refer to 7; for his death, refer to 8; for his learning, religion and travels, refer to 9; for his trade and reputation, refer to 10; for his friends, refer to 11; and finally for questions connected with his enemies, refer to house 12. I proceed to describe briefly the influences of the planets, and shall then mention those of the zodiacal signs; I should note however that in practice the signs were in many respects more influential than the planets. The astrological “planets” were seven in number, and included the Sun and the Moon. They were Saturn or the Great Infortune, Jupiter or the Great Fortune, Mars or the Lesser Infortune, the Sun, Venus or the Lesser Fortune, Mercury, and the Moon: the above order being that of their apparent times of rotation round the earth. Each of them had a double signification. In the first place it impressed certain characteristics, such as good fortune, feebleness, &c., on the dealings of the native with the subjects connected with the house in which it was located; and in the second place it imported certain objects into the house which would affect the dealings of the native with the subjects of that house. 240 ASTROLOGY. [CH. X To describe the exact influence of each planet in each house would involve a long explanation, but the general effect of their presence may be indicated roughly as follows* . The presence of Saturn is malignant: that of Jupiter is propitious: that of Mars is on the whole injurious: that of the Sun indicates respectability and moderate success: that of Venus is rather favourable: that of Mercury implies rapid practical action: and lastly the presence of the Moon merely faintly reflects the influence of the planet nearest her, and suggests rapid changes and fickleness. Besides the planets, the Moon’s nodes and some of the more prominent fixed stars† also had certain influences. These vague terms may be illustrated by taking a few simple cases. For example, in casting a nativity, the life, health, and general career of the native were determined by the first or ascendant house, whence comes the expression that a man’s fortune is in the ascendant. Now the most favourable planet was Jupiter. Therefore, if at the instant of birth Jupiter was in the first house, the native might expect a long, happy, healthy life; and being born under Jupiter he would have a “jovial” disposition. On the other hand, Saturn was the most unlucky of all the planets, and was as potent as malignant. If at the instant of birth he was in the first house, his potency might give the native a long life, but it would be associated with an angry and unhappy temper, a spirit covetous, revengeful, stern, and unloveable, though constant in friendship no less than in hate, which was what astrologers meant by a “saturnine” character. Similarly a native born under Mercury, that is, with Mercury in the first house, would be of a mercurial nature, while anyone born under Mars would have a martial bent. Moreover it was the prevalent opinion that a jovial person would have his horoscope affected by Jupiter, even if that planet had not been in the ascendant at the time of birth. Thus the horoscope of an adult depended to some extent on his character and previous life. It is hardly necessary to point out how easily this

doctrine enabled an astrologer to make the prediction of the heavens agree with facts that were known or probable. In the same way the other houses are affected. For instance, no astrologer, who believed in the art, would have wished to start on a long journey when Saturn was in the ninth house or house of travels; * Raphael, pp. 70–90; pp. 204–209. † Raphael, pp. 129–131, CH. X] ASTROLOGY. 241 and, if at the instant of birth Saturn was in that house, the native always would incur considerable risk on his journeys. Moreover every planet was affected to some extent by its aspect (conjunction, opposition, or quadrature) to every other planet according to elaborate rules* which depended on their positions and directions of motion: in particular the angular distance between the Sun and the Moon—sometimes known as the "part of fortune"—was regarded as specially important, and this distance affected the whole horoscope. In general, conjunction was favourable, quadrature unfavourable, and opposition ambiguous. Each planet not only influenced the subjects in the house in which it was situated, but also imported certain objects into the house. Thus Saturn was associated with grandparents, paupers, beggars, labourers, sextons, and gravediggers. If, for example, he was present in the fourth house, the native might look for a legacy from some such person; if he was present in the twelfth house, the native must be careful of the consequences of the enmity of any such person; and so on. Similarly Jupiter was associated generally with lawyers, priests, scholars, and clothiers; but, if he was conjoined with a malignant planet, he represented knaves, cheats, and drunkards. Mars indicated soldiers (or, if in a watery sign, sailors on ships of war), masons, doctors, smiths, carpenters, cooks, and tailors; but, if afflicted with Mercury or the Moon, he denoted the presence of thieves. The Sun implied the action of kings, goldsmiths, and coiners; but, if afflicted by a malignant planet, he denoted false pretenders. Venus imported musicians, embroiderers, and purveyors of all luxuries; but, if afflicted, prostitutes and bullies. Mercury imported astrologers, philosophers, mathematicians, statesmen, merchants, travellers, men of intellect, and cultured workmen; but, if afflicted, he signified the presence of pettifoggers, attorneys, thieves, messengers, footmen, and servants. Lastly, the presence of the Moon introduced sailors and those engaged in inferior offices. I come now to the influence and position of the zodiacal signs. So far as the first house was concerned, the sign of the zodiac which was there present was even more important than the planet or planets, for it was one of the most important indications of the durations of life. Each sign was connected with certain parts of the body—ex. gr. Aries influenced the head, neck and shoulders—and that part of the * Raphael, pp. 132–170. 242 ASTROLOGY. [CH. X body was affected according to the house in which the sign was. Further each sign was associated with certain countries and connected the subjects of the house in which the sign was situated with those countries: ex. gr. Aries was associated especially with events in England, France, Syria, Verona, Naples, &c. The sign

in the first house determined also the character and appearance of the native* . Thus the character of a native born under Aries (m) was passionate; under Taurus (f) was dull and cruel; under Gemini (m) was active and ingenious; under Cancer (f) was weak and yielding; under Leo (m) was generous, resolute, and ambitious; under Virgo (f) was sordid and mean; under Libra (m) was amorous and pleasant; under Scorpio (f) was cold and reserved; under Sagittarius (m) was generous, active, and jolly; under Capricorn (f) was weak and narrow; under Aquarius (m) was honest and steady; and under Pisces (f) was phlegmatic and effeminate. Moreover the signs were regarded as alternately masculine and feminine, as indicated above by the letters m or f placed after each sign. A masculine sign is fortunate, and all planets situated in the same house have their good influence rendered thereby more potent and their unfavourable influence mitigated. But all feminine signs are unfortunate, their direct effect is evil, and they tend to nullify all the good influence of any planet which they afflict (i.e. with which they are connected), and to increase all its evil influences, while they also import an element of fickleness into the house and often turn good influences into malignant ones. The precise effect of each sign was different on every planet. I think the above account is sufficient to enable the reader to form a general idea of the manner in which a horoscope was cast and interpreted, and I do not propose to enter into further details. This is the less necessary as the rules—especially as to the relative importance to be assigned to various planets when their influence was conflicting—were so vague that astrologers had little difficulty in finding in the horoscope of a client any fact about his life of which they had information or any trait of character which they suspected him to possess. That this vagueness was utilized by quacks is notorious, but no doubt many an astrologer in all honesty availed himself of it, whether consciously or unconsciously. It must be remembered also that the rules were laid down at a time when men were unacquainted with any exact * Raphael, pp. 61–69. CH. X] ASTROLOGY. 243 science, with the possible exception of mathematics, and further that, if astrology had been reduced to a series of inelastic rules applicable to all horoscopes, the number of failures to predict the future correctly would have rapidly led to a recognition of the folly of the art. As it was, the failures were frequent and conspicuous enough to shake the faith of most thoughtful men. Moreover it was a matter of common remark that astrologers showed no greater foresight in meeting the difficulties of life than their neighbours, while they were neither richer, wiser, nor happier for their supposed knowledge. But though such observations were justified by reason they were often forgotten in times of difficulty and danger. A prediction of the future and the promise of definite advice as to the best course of action, revealed by the heavenly bodies themselves, appealed to the strongest desires of all men, and it was with reluctance that the futility of the advice was gradually recognized. The objections to the scheme

had been stated clearly by several classical writers. Cicero* pointed out that not one of the futures foretold for Pompey, Crassus, and Caesar had been verified by their subsequent lives, and added that the planets, being almost infinitely distant, cannot be supposed to affect us. He also alluded to the fact, which was especially pressed by Pliny† , that the horoscopes of twins are practically identical though their careers are often very different, or as Pliny put it, every hour in every part of the world are born lords and slaves, kings and beggars. In answer to the latter obvious criticism astrologers replied by quoting the anecdote of Publius Nigidius Figulus, a celebrated Roman astrologer of the time of Julius Caesar. It is said that when an opponent of the art urged as an objection the different fates of persons born in two successive instants, Nigidius bade him make two contiguous marks on a potter's wheel, which was revolving rapidly near them. On stopping the wheel, the two marks were found to be far removed from each other. Nigidius received the name of Figulus, the potter, in remembrance of this story, but his argument, says St Augustine‡ , who gives us the narrative, was as fragile as the ware which the wheel manufactured. On the other hand Seneca and Tacitus may be cited as being on * Cicero, De Divinatione, ii, 42. † Pliny, Historia Naturalis, vii, 49; xxix, 1. ‡ St Augustine, De Civitate Dei, bk. v, chap. iii; Opera omnia, ed. Migne, vol. vii, p. 143. 244 ASTROLOGY. [CH. X the whole favourable to the claims of astrology, though both recognized that it was mixed up with knavery and fraud. An instance of successful prediction which is given by the latter of these writers* may be used more correctly as an illustration of how the ordinary professors of the art varied their predictions to suit their clients and themselves. The story deals with the first introduction of the astrologer Thrasyllus to the emperor Tiberius. Those who were brought to Tiberius on any important matter were admitted to an interview in an apartment situated on a lofty cliff in the island of Capreae. They reached this place by a narrow path overhanging the sea, accompanied by a single freedman of great bodily strength; and on their return, if the emperor had conceived any doubts of their trustworthiness, a single blow buried the secret and its victim in the ocean. After Thrasyllus had, in this retreat, stated the results of his art as they concerned the emperor, the latter asked the astrologer whether he had calculated how long he himself had to live. The astrologer examined the aspect of the stars, and while he did this showed, as the narrative states, hesitation, alarm, increasing terror, and at last declared that the present hour was for him critical, perhaps fatal. Tiberius embraced him, and told him he was right in supposing he had been in danger but that he should escape it; and made him thenceforth a confidential counsellor. But Thrasyllus would have been but a sorry astrologer had he not foreseen such a question and prepared an answer which he thought fitted to the character of his patron. A somewhat similar story is told† of Louis XI of France. He sent for a famous astrologer whose death he was meditating, and asked him to show his skill by

foretelling his own future. The astrologer replied that his fate was uncertain, but it was so inseparably interwoven with that of his questioner that the latter would survive him but by a few hours, whereon the superstitious monarch not only dismissed him uninjured, but took steps to secure his subsequent safety. The same anecdote is also related of a Scotch student who, being captured by Algerian pirates, predicted to the Sultan that their fates were so involved that he should predecease the Sultan by only a few weeks. This may have been good enough for a barbarian, but with a civilized monarch it * Annales, vi, 22: quoted by Whewell, History of the Inductive Sciences, vol. i, p. 313. † Personal Characteristics from French History, by Baron F. Rothschild, London, 1896, p. 10. The story was introduced by Sir Walter Scott in Quentin Durward (chap. xv). CH. X] ASTROLOGY. 245 probably would in most cases be less effectual, as certainly it is less artistic, than the answer of Thrasyllus. I may conclude by mentioning a few notable cases of horoscopy. Among the most successful instances of horoscopy enumerated by Raphael* is one by W. Lilly, given in his Monarchy or No Monarchy, published in 1651, in which he predicted a plague in London so terrible that the number of deaths should exceed the number of coffins and graves, to be followed by "an exorbitant fire." The prediction was amply verified in 1665 and 1666. In fact Lilly's success was embarrassing, for the Committee of the House of Commons, which sat to investigate the causes of the fire and ultimately attributed it to the papists, thought that he must have known more about it than he chose to declare, and on Oct. 25, 1666, summoned him before them. I may add that Lilly proved himself a match for his questioners. An even more curious instance of a lucky hit is told of Flamsteed† , the first astronomer royal. It is said that an old lady who had lost some property wearied Flamsteed by her perpetual requests that he would use his observatory to discover her property for her. At last, tired out with her importunities, he determined to show her the folly of her demand by making a prediction, and, after she had found it false, to explain again to her that nothing else could be expected. Accordingly he drew circles and squares round a point that represented her house and filled them with all sorts of mystical symbols. Suddenly striking his stick into the ground he said, "Dig there and you will find it." The old lady dug in the spot thus indicated, and found her property; and it may be conjectured that she believed in astrology for the rest of her life. Perhaps the belief that the royal observatory was built for such purposes may be still held, for De Morgan, writing in 1850, says that "persons still send to Greenwich to have their fortunes told, and in one case a young gentleman wrote to know who his wife was to be, and what fee he was to remit." It is easier to give instances of success in horoscopy than of failure. Not only are all ambiguous predictions esteemed to be successful, but it is notorious that prophecies which have been verified by the subsequent * Manual of Astrology, p. 37. † The story, though in a slightly different setting, is given in The London Chronicle, Dec. 3, 1771, and

it is there stated that Flamsteed attributed the result to the direct action of the devil. 246 ASTROLOGY. [CH. X course of events are remembered and quoted, while the far more numerous instances in which the prophecies have been falsified are forgotten or passed over in silence. As exceptionally well-authenticated instances of failures I may mention the twelve cases collected by Cardan in his Geniturarum Exempla. These are good examples because Cardan was not only the most eminent astrologer of his time, but was a man of science, and perhaps it is not too much to say was accustomed to accurate habits of thought; moreover, as far as I can judge, he was perfectly honest in his belief in astrology. To English readers the most interesting of these is the horoscope of Edward VI of England, the more so as Cardan has left a full account of the affair, and has entered into the reasons of his failure to predict Edward's death. To show how Cardan came to be mixed up in the transaction I should explain that in 1552 Cardan went to Scotland to prescribe for John Hamilton, the archbishop of St Andrews, who was ill with asthma and dropsy and about whose treatment the physicians had disagreed* . On his return through London, Cardan stopped with Sir John Cheke, the Professor of Greek at Cambridge, who was tutor to the young king. Six months previously, Edward had been attacked by measles and smallpox which had made his health even weaker than before. The king's guardians were especially anxious to know how long he would live, and they asked Cardan to cast Edward's nativity with particular reference to that point. The Italian was granted an audience in October, of which he wrote a full account in his diary, quoted in the Geniturarum Exempla. The king, says he† , was "of a stature somewhat below the middle height, pale faced, with grey eyes, a grave aspect, decorous, and handsome. He was * Luckily they left voluminous reports on the case and the proper treatment for it. The only point on which there was a general agreement was that the phlegm, instead of being expectorated, collected in his Grace's brains, and that thereby the operations of the intellect were impeded. Cardan was celebrated for his success in lung diseases, and his remedies were fairly successful in curing the asthma. His fee was 500 crowns for travelling expenses from Pavia, 10 crowns a day, and the right to see other patients; the archbishop actually gave him 2300 crowns in money and numerous presents in kind; his fees from other persons during the same time must have amounted to about an equal sum (see Cardan's De Libris Propriis, ed. 1557, pp. 159–175; Consilia Medica, Opera, vol. ix, pp. 124–148; De Vita Propria, ed. 1557, pp. 138, 193 et seq.). † I quote from Morley's translation, vol. ii, p. 135 et seq. CH. X] ASTROLOGY. 247 rather of a bad habit of body than a sufferer from fixed diseases, and had a somewhat projecting shoulder-blade." But, he continues, he was a boy of most extraordinary wit and promise. He was then but fifteen years old and he was already skilled in music and dialectics, a master of Latin, English, French, and fairly proficient in Greek, Italian, and Spanish. He "filled with the highest expectation every good

and learned man, on account of his ingenuity and suavity of manners. . . . When a royal gravity was called for, you would think that it was an old man you saw, but he was bland and companionable as became his years. He played upon the lyre, took concern for public affairs, was liberal of mind, and in these respects emulated his father, who, while he studied to be [too] good, managed to seem bad." And in another place* he describes him as "that boy of wondrous hopes." At the close of the interview Cardan begged leave to dedicate to Edward a work on which he was then engaged. Asked the subject of the work, Cardan replied that he began by showing the cause of comets. The subsequent conversation, if it is reported correctly, shows good sense and considerable logical skill on the part of the young king. * De Rerum Varietate, p. 285. 248 ASTROLOGY. [CH. X I have reproduced on the previous page a facsimile of Cardan's original drawing of Edward's horoscope. The horoscope was cast and read with unusual care. I need not quote the minute details given about Edward's character and subsequent career, but obviously the predictions were founded on the impressions derived from the abovementioned interview. The conclusion about his length of life was that he would certainly live past middle age, though after the age of 55 years 3 months and 17 days various diseases would fall to his lot* . In the following July the king died, and Cardan felt it necessary for his reputation to explain the cause of his error. The title of his dissertation is Quae post consideravi de eodem† . In effect his explanation is that a weak nativity can never be predicted from a single horoscope, and that to have ensured success he must have cast the nativity of every one with whom Edward had come intimately into contact; and, failing the necessary information to do so, the horoscope could be regarded only as a probable prediction. This was the argument usually offered to account for non-success. A better defence would have been the one urged by Raphael‡ and by Southey§ that there might be other planets unknown to the astrologer which had influenced the horoscope, but I do not think that medieval astrologers assigned this reason for failure. I have not alluded to the various adjuncts of the art, but astrologers so frequently claimed the power to be able to raise spirits that perhaps I may be pardoned for remarking that I believe some of the more important and elaborate of these deceptions were effected not infrequently by means of a magic lantern, the pictures being sometimes thrown on to a mirror, and at other times on to a thick cloud of smoke which caused the images to move and finally disappear in a fantastic way capable of many explanations‖ . I would conclude by repeating again that though the practice of astrology was so often connected with impudent quackery, yet one ought not to forget that nearly every physician and man of science in medieval Europe was an astrologer. These observers did not consider that its * Geniturarum Exempla, p. 19. † Ibid., p. 23. ‡ The Familiar Astrologer, London, 1832, p. 248. § The Doctor, chap. 92. ‖ See ex. gr. the life of Cellini, chap. xiii, Roscoe's translation, pp. 144-146. See also Sir David Brewster's

Letters on Natural Magic. CH. X] ASTROLOGY. 249 rules were definitely established, and they laboriously collected much of the astronomical evidence that was to crush their art. Thus, though there never was a time when astrology was not practised by knaves, there was a period of intellectual development when it was honestly accepted as a difficult but a real science. CHAPTER XI. CRYPTOGRAPHS AND CIPHERS. The art of constructing cryptographs or ciphers—intelligible to those who know the key and unintelligible to others—has been studied for centuries. Their usefulness on certain occasions, especially in time of war, is obvious, while it may be a matter of great importance to those from whom the key is concealed to discover it. But the romance connected with the subject, the not uncommon desire to discover a secret, and the implied challenge to the ingenuity of all from whom the key is hidden, have attracted to the subject the attention of many to whom its utility is a matter of indifference. The leading authorities on the subject, few of which are less than a century old, are enumerated in an article by J.E. Bailey in the ninth edition of the Encyclopaedia Britannica, and references to various historic ciphers are there given. My knowledge of the subject, however, is limited to ciphers which I have met with in the course of casual reading, and I prefer to discuss the subject as it has presented itself to me, with no attempt to make it historically complete and no reference to other authorities. In fact the theory of the subject is not sufficiently important to make it worth while to try to deal with it historically or exhaustively. Most writers use the words cryptograph and cipher as synonymous. I employ them, however, with different meanings, which I proceed to define. A cryptograph may be defined as a manner of writing in which the letters or symbols employed are used in their normal sense, but are so arranged that the communication is intelligible only to those possessing 250 CH. XI] CRYPTOGRAPHS AND CIPHERS. 251 the key. The word is sometimes used to denote the communication made. A simple example is a communication in which every word is spelt backwards. Thus: ymene deveileb ot eb gniriter troper noitisop no ssorc daor. A cipher may be defined as a manner of writing by characters arbitrarily invented or by an arbitrary use of letters, words, or characters in other than their ordinary sense, intelligible only to those possessing the key. The word is sometimes used to denote the communication made. A simple example is when each letter is replaced by the one that immediately follows it in the natural order of the alphabet, a being replaced by b, b by c, and so on, and finally z by a. In this cipher the above message would read: fofnz cfmjfwfe up cf sfujsjoh sfqpsu qptjujpo po dsptt spbe. In both cryptographs and ciphers the essential feature is that the communication may be freely given to all the world though it is unintelligible save to those who possess the key. The key must not be accessible to anyone, and if possible it should be known only to those using the cryptograph or cipher. The art of constructing a cryptograph lies in the concealment of the proper order of the essential letters or words: the art of

constructing a cipher lies in concealing what letters or words are represented by the symbols used. In an actual communication cipher symbols may be arranged cryptographically, and thus further hinder a reading of the message. Thus the message given above would read in a cryptographic cipher as znfof efwfjmfc pu fc hojsjufs uspqfs opjujtpq op ttpsd ebps. If the message were sent in Latin or some foreign language it would further diminish the chance of it being read by a stranger through whose hands it passed. But I may confine myself to messages in English, and for the present to simple cryptographs and ciphers. A communication in cryptograph or cipher must be in writing or in some permanent form. Thus to make small muscular movements— such, ex. gr., as talking on the fingers, or breathing long and short in the Morse dot and dash system, or making use of pre-arranged signs by a fan or stick, or flashing signals by light—do not here concern us. 252 CRYPTOGRAPHS AND CIPHERS. [CH. XI Again, the mere fact that the message is concealed or conveyed secretly does not make it a cryptograph or cipher. The majority of stories dealing with secret communications are concerned with the artfulness with which the message is concealed or conveyed and have nothing to do with cryptographs or ciphers. Many of the ancient instances of secret communication are of this type* . Illustrations are to be found in messages conveyed by pigeons, or wrapped round arrows shot over the head of a foe, or written on the paper wrapping of a cigarette, or the use of ink which becomes visible only when the recipient treats the paper on which it is written by some chemical or physical process. Again, a communication in a foreign language or in any recognized notation like shorthand is not an instance of a cipher. A letter in Chinese or Polish or Russian might be often used for conveying a secret message from one part of England to another, but it fails to fulfil our test that if published to all the world it would be concealed from everyone, unless submitted to some special investigation. On the other hand, in practice, foreign languages or systems of shorthand which are but little known may serve to conceal a communication better than an easy cipher, for in the last case the key may be found with but little trouble, while in the other cases, though the key may be accessible, it is probable that there are only a few who know where to look for it. An illustration of this is afforded by the system used by Pepys in writing his Diary which is further alluded to below. I proceed to enumerate some of the better known types of cryptographs. There are at least three distinct types. The first type comprises those in which the order of the letters is changed in some prearranged manner. The second type comprises those in which the concealment is due to the introduction of non-significant letters. The third type comprises those in which the letters used are written in fragments. The types are not exclusive, and any particular cryptograph may comprise the distinctive feature of two or all the types. A cryptograph of the first type is one in which the successive letters of the message are re-arranged in some pre-determined manner. One of the most

obvious cryptographs of this type is to write each word or the message itself backwards. He would, however, be a careless reader who could be deceived by this. Here is an instance in which the * A long list of classical authorities for different devices used in ancient times for concealing messages is given in Mercury by J. Wilkins, London, 1641, pp. 27–36. CH. XI] CRYPTOGRAPHS 253 whole message is written backwards: tsop yb tnes tnemeerga fo seniltuo smret ruo tpecca yeht. In such a case it is unnecessary to indicate the division into words by leaving spaces between them, and we might divide the letters artificially, as thus: Ts opybtne stne meer gafos eniltu osmret ruot peccaye ht. Systems of this kind which depend on altering the places of letters or lines in some pre-arranged manner have always been common. I quote a couple of instances* from Wilkins's book to which I have already referred—it was a work which seems to have been studied diligently by many of those who took part in the civil disturbances of the 17th century, and gives an excellent account of some of the easier systems of cryptographs and ciphers. The first example I take from him is where the letters which make up the communication are written vertically up or down. Thus the message: The pestilence continues to increase might be written thus: e i o t n l i t s n t i o e t h a c s n c n s e e r e u e c e p Again, Wilkins says that the cryptograph may be yet further obscured by placing the letters which make up the message in any prearranged but discontinuate order. For instance if the message runs to four lines we may put the first letter at the beginning of the first line, the second at the beginning of the fourth line, the third at the end of the first line, the fourth at the end of the fourth line, the fifth at the beginning of the second line, the sixth at the beginning of the third line, the seventh at the end of the second line, the eighth at the end of the third line, and so on. Thus the message: Wee shall make an Irruption upon the Enemie, from the North, at ten of the clock this * Mercury, or the Secret and Swift Messenger, by J. Wilkins, London, 1641, pp. 50–52. 254 CRYPTOGRAPHS AND CIPHERS. [CH. XI night would read thus: Wm rpeta hhs cteinpke haih fonoih kftoe nil anoerr ocgt tthmnu rl eauo mhtei nlen ettes, where, to obscure the message further, it is divided arbitrarily into what appear to be words. Another instance of a cryptograph of this type may be constructed thus. First, by writing the message in lines of some arranged length, say, for instance, each containing seventeen letters—the letters in successive lines being arranged vertically under those corresponding to them in the upper line—and either leaving no spaces between the words or inserting some pre-arranged letter or letters or digits between them, such as j, q, z. The message can be then sent as a cryptograph by writing the letters in order in successive vertical lines. This only comes to saying that we write successively the 1st, 18th, 35th letters of the original message, and then the 2nd, 19th, 36th letters, and so on. To confuse the decipherer the final reading may be arbitrarily put into what might represent words. If, however, we know the clue number,

say c, it is easy enough to read the communication. For if it divides into the number of letters n times with a remainder r it suffices to re-write the message in lines putting n + 1 letters in each of the first r lines, and n letters in each of the last c − r lines, and then the communication can be read by reading the columns downwards. For instance, if the following communication, containing 270 letters, were received: Ahtzeipqhgesoa eouazsesewaeqtmusfdtbenzcesjteottqizyczhtzjioarhqettjrfesftnzmroomoh yearziaqneornbreotlennkaerwizesjuasjodezwjzzszjbrrittjnfjlweuzroqyfoht qayeizsleopjidihaloalhpepkrheanazsrvliimosiadygtpekijscerqvvjqjqajqnyji ntkaehsbhsnbgoaotqetqeuuesayqurntpebqstzamztqrj , and the clue number were 17 we should put 16 letters in each of the first 15 lines and 15 letters in each of the last 2 lines. The communication could then be discovered by reading the columns downwards: the letters j, q, and z marking the ends of words. Another cryptograph of this type may be constructed by arranging the letters cyclically, and agreeing that the communication is to be made by selected letters, as, for instance, every seventh, second, seventh, second, and so on. Thus if the communication were Ammunition CH. XI] CRYPTOGRAPHS 255 too low to allow of a sortie, which consists of 32 letters, the successive significant letters would come in the order 7, 9, 16, 18, 25, 27, 2, 4, 13, 15, 24, 28, 5, 8, 20, 22, 1, 6, 21, 26, 11, 14, 32, 10, 31, 12, 17, 23, 3, 29, 30, 19—the numbers being selected as in the decimation problem given above on pages 19–20, and being struck out from the 32 cycle as soon as they are determined. The above communication would then read Ttriooalmolaoonmsueoawotnliotifw. This is a good cryptograph, but it is troublesome to construct, especially if the message is long, and for that reason is not to be recommended. A cryptograph of the second type is one in which the message is expressed in ordinary writing, but in it are introduced a number of dummies or non-significant letters or digits thus concealing which of the letters are relevant. One way of picking out those letters which are relevant is by the use of a perforated card of the shape of (say) a sheet of note-paper, which when put over such a sheet permits only such letters as are on certain portions of it to be visible. Such a card is known as a grille. An example of a grille with four openings is figured below. A communication made in this way may be easily concealed from anyone who does not possess A B CD a card of the same pattern. If the recipient possesses such a card he has only to apply it in order to read the message. The use of the grille may be rendered less easy to detect if it be used successively in different positions, for instance, with the edges AB and CD successively put along the top of the paper containing the message. On the next page, for instance, is a message which, with the aid of the grille figured above, is at once intelligible. On applying the grille to it with the line AB along the top HK we get the first half of the communication, namely, 1000 rifles se. On applying the grille with the line CD along the top HK we get the rest of the message, 256

CRYPTOGRAPHS AND CIPHERS. [CH. XI namely, nt to L to-day. The other spaces in the paper are filled with non-significant letters or numerals in any way we please. Of course any one using such a grille would not divide the sheet of paper on which the communication was written into cells, but in the figure I have done so in order to render the illustration clearer. 981 264 070 523 479 100 NT T ORI SON SON AHY DT C BF S P UM OLT KF E LJO EGX AEU QJT EGO F LE HV E W LA FML AES REM REM ODA SSE Y ZZ EP D QJC EKS T IM OEF H K We can avoid the awkward expedient of having to use a perforated card, which may fall into undesired hands, by introducing a certain pre-arranged number of dummies or non-significant letters or symbols between those which make up the message. Thus, to take an extreme case, we might arrange that only every 101st letter should form our communication, and the intervening 100 letters should be written at random. But such a communication would be 101 times longer than the message, a nearly fatal objection if it had to be written in a hurry or telegraphed. A better method, and one which is not easily discovered by a stranger, is to arrange that (say) only every alternate second and third letter shall be relevant. Thus the first, third, sixth, eighth, eleventh, etc., letters are those that make up the message. Such a communication would be only two and a half times as long as the message, but even that might be a great disadvantage if time in sending the message was of importance. For a message written at leisure this need not matter much, and in such a code the introduction of a sufficient number of unnecessary letters in some pre-arranged manner gives an effectual means of conveying a message in secret. We can also avoid the use of a perforated card if it be arranged that every n th word shall give the message, the other words being nonsignificant, though of course inserted as far as possible so as to make the complete communication run as a whole. But the difficulty of composing a document of this kind and its great length render it unsuitable for any purpose except an occasional communication composed at leisure CH. XI] CRYPTOGRAPHS 257 and sent in writing. This method is said to have been used by the Earl of Argyle when plotting against James II. Similarly any system that rests on picking out certain letters in a document, which letters form a communication in ordinary writing, is a cryptograph. Thus a communication conveyed by a newspaper, in which the letters making up the message are indicated by pen dots or pin pricks or in some other agreed way, is a cryptograph. A kind of secret writing which may perhaps be considered to constitute a third type of cryptograph is a communication on paper which is legible only when the paper is folded in a particular way. An example is a message written across the edges of a strip of paper wrapped spiralwise round a stick called a scytale. When the paper is unwound and taken off the stick the letters appear broken, and may seem to consist of arbitrary signs, but by wrapping the paper round a similar stick the message can be again read. This system is said to have been used by the Lacedemonians* . The

concealment can never have been effectual against an intelligent reader who got possession of the paper. The defect of the method is that the broken letters at once attract attention and suggest the system used. If the fact can be concealed that the visible symbols are parts of letters the cryptograph would be much improved. As an illustration take the appended communication which is said to have been given to the Young Pretender during his wanderings after Culloden. If it be creased along the lines BB and CC (CC being along the second line of the second score), and then folded over, with B inside, so that the crease C lies over the line A (which is the second line of the first score) thus leaving only the top * For references, see Wilkins, supra, p. 38. 258 CRYPTOGRAPHS AND CIPHERS. [CH. XI and bottom of the piece of paper visible, it will be found to read conceal yourself, your foes look for you. I have seen what purports to be the original, but of the truth of the anecdote I know nothing, and the desirability of concealing himself must have been so patent that it was hardly necessary to communicate it by a cryptograph. I proceed next to some of the more common types of ciphers. It is immaterial whether we invent characters to denote the various letters; or whether we employ special symbols to represent them, such as the symbol (for a, the symbol : for b, and so on; or whether we use the letters in a non-natural sense, such as the letter z for a, the letter y for b, and so on. The rules for reading the cipher will be the same in each case. In early times it was a common practice to invent arbitrary symbols to represent the letters. If the symbols are invented for the purpose they provoke attention, hence it would seem that preferably we should use symbols which are not likely to attract special notice. For instance, the symbols may be musical notes, in which case the message would appear as a piece of music. Geometrical figures have also been used for the same purpose. It is not even necessary to employ written signs. Natural objects have often been used, as in a necklace of beads, or a bouquet of flowers, where the different shaped or coloured beads or different flowers stand for different letters or words. An even more subtle form of disguising the cipher is to make the different distances between consecutive knots or beads indicate the different letters. Of all such systems we may say that a careful scrutiny shows that different symbols are being used, and as soon as the various symbols are distinguished one from the other no additional complication is introduced, while for practical purposes they are more trouble to send or receive than those written in symbols in current use. Accordingly I confine myself to ciphers written by the use of the current letters and numerals. It is convenient to divide ciphers into four classes. The first class comprises ciphers in which the same letter or word is always represented by the same symbol, and this symbol always represents the same letter or word. The second class comprises ciphers in which the same letter or word is, in some or all cases, represented by more than one symbol, and this symbol always represents the same letter or word. The third class

comprises ciphers in which the same symbol represents sometimes CH. XI] CIPHERS 259 one letter or word and sometimes another. The fourth class comprises ciphers in which each letter or word is always represented by the same symbol, but more than one letter or word may be represented by the same symbol. A cipher of the first type then is one in which the same letter or word is always represented by the same symbol, and this symbol always represents the same letter or word. Perhaps the simplest illustration of a cipher of this type is to employ one language, but written as far as practical in the alphabet of another language. It is said that during the Indian Mutiny messages in English, but written in Greek characters, were used freely, and successfully baffled the ingenuity of the enemy, into whose hands they fell. If this is true, the intelligence of the Hindoos must have been much less than that with which they are usually credited. The device, however, is an old one, for we are told* that Edward VI was accustomed to make notes in cipher “with Greek characters, to the end that they who waited on him should not read them.” A common cipher of this type is made by using the actual letters of the alphabet, but in a non-natural sense as indicating other letters. Thus we may use each letter to represent the one immediately following it in the natural order of the alphabet—the letters being supposed to be cyclically arranged—a standing for b wherever it occurs, b standing for c, and so on, and finally z standing for a. Or more generally we may write the letters of the alphabet in a line, and under them re-write the letters in any order we like. For instance a b c d e f g h i j k l m n o p q r s t u v w x y z o l k m a z s q x e u f y r t h c w b v n i d g j p In such a scheme, we must in our communication replace a by o, b by l, etc. The recipient will prepare a key by rearranging the letters in the second line in their natural order and placing under them the corresponding letter in the first line. Then wherever a comes in the message he receives he will replace it by e; similarly he will replace b by s, and so on. A cipher of this kind is not uncommonly used in military signalling, the order of the letters being given by the use of a key-word. If, for instance, Pretoria is chosen as the key-word, we write the letters in * Sir John Hayward, Life of Edward VI., edition of 1636, p. 20. 260 CRYPTOGRAPHS AND CIPHERS. [CH. XI this order, striking out any which occur more than once, and continue with the unused letters of the alphabet in their natural order, writing the whole in two lines thus: p r e t o i a b c d f g h z y x w v u s q n m l k j Then in using the cipher p is replaced by z and vice versâ, r by y, and so on. A long message in such a cipher would be easily discoverable, but it is rapidly composed by the sender and read by the receiver, and for some purposes may be useful, especially if the discovery of the purport of the message is, after a few hours, immaterial. A summary of the usual rules for reading ciphers of this type, whether written in English, French, German, Italian, Dutch, Latin, or Greek, was given by D.A. Conradus in 1742* ; and similar rules have been given by various later writers. In English the letter which occurs most frequently is e. The next most common

letters are said to be t, a, o, and i; then n; then r, s, and h; then d and l; then c, w, u, and m; then f, y, g, p, and b; then v and k; and then x, q, j, and z. The most common double letters are ee, ll, oo, and ss; while in more than half the cases of a double letter at the end of a word, the letter is either l or s. Also, t and h form a common conjunction. I need not, however, go here into further details of this kind. Assuming that the division into words is given, that non-significant symbols are not introduced, and that the problem is not complicated by the avoidance of the use of common words, a communication of any considerable length can usually be read with but little difficulty. The hints given by Conradus will at once suggest certain hypotheses as to which letters stand for which. Taking one of these hypotheses we write the message, replacing the symbols by the letters we conjecture that they represent and replace the others by dots. If the hypothesis is tenable, the arrangement will probably suggest some of the missing letters. If, for example, we find two words emphs-all and empht-e where the missing letter is represented by the same symbol, the first word shows us that the missing letter is h, m, or t, and the second word shews us that it must be e, h, i, or o, hence it must be h. Every fresh letter so determined makes the hypothesis more probable and renders * Gentleman's Magazine, 1742, vol. xii, pp. 133–135, 185–186, 241–242, 473–475. See also the Collected Works of E.A. Poe in 4 volumes, vol. i, p. 30 et seq. CH. XI] CIPHERS 261 it easier to guess what the remaining symbols represent. The chief difficulty is to get a working hypothesis for the first few letters—if it is the true solution, probably the puzzle will be readily solved—but to make up a working hypothesis for even a few letters requires patience. Ciphers of this class in which the division between the words is given are to be avoided. If we leave a space between such words a would-be decipherer is given an immense help. He will naturally try if a word denoted by a single symbol can be an i or an a, while the words of two or three letters will often stand revealed and so provide a definite groundwork on which he can construct the key. A long word may also betray the secret. For instance, if the decipherer has reason to suspect that the message related to something connected with Birmingham, and he found that a particular word of ten letters had its second and fifth letters alike, as also its fourth and tenth letters, he would naturally see how the key would work if the word represented Birmingham, and on this hypothesis would at once know the letters represented by eight symbols. With reasonable luck this should suffice to enable him to tell if the hypothesis was tenable. The effect of this can be avoided by leaving no spaces between the words, but this might lead to confusion and is not to be recommended. We can also use letters which occur but rarely, such as j, q, x, z, to separate words, and probably this is the best method. Ciphers of this type suggest themselves naturally to those approaching the subject for the first time, and are commonly made by merely shifting the letters a certain number of places forward. If this is done we may decrease the risk of detection by

altering the amount of shifting at short (and preferably irregular) intervals. Thus it may be agreed that if initially we shift every letter one place forward then whenever we come to the letter (say) n we shall shift every letter one more place forward. In this way the cipher changes continually, and is essentially changed to one of the third class; but even with this improvement it is probable that an expert would decode a fairly long message without much difficulty. We can have ciphers for numerals as well as for letters: such ciphers are common in many shops. Any word or sentence containing ten different letters will answer the purpose. Thus, an old tradesman of my acquaintance used the excellent precept Be just O Man—the first letter representing 1, the second 2, and so on. In this cipher the price 10/6 262 CRYPTOGRAPHS AND CIPHERS. [CH. XI would be marked bn/t. This is an instance of a cipher of the first type. A cipher of the second type is one in which the same letter or word is, in some or all cases, represented by more than one symbol, and this symbol always represents the same letter or word. Such ciphers were uncommon before the Renaissance, but the fact that to those who held the key they were not more difficult to write or read than ciphers of the first type, while the key was not so easily discovered, led to their common adoption in the seventeenth century. A simple instance of such a cipher is given by the use of numerals to denote the letters of the alphabet. Thus a may be represented by 11 or by 37 or by 63, b by 12 or by 38 or by 64, and so on, and finally z by 36 or by 62 or by 88, while we can use 89 or 90 to signify the end of a word and the numbers 91 to 99 to denote words or sentences which constantly occur. Of course in practice no one would employ the numbers in an order like this, which suggests their meaning, but it will serve to illustrate the principle. I have deliberately used numbers of only two digits, as the recipient can then point off the symbols used in twos, and will know that each pair of symbols represents a letter, word, or sentence in the message. A disadvantage of this cipher is that since each letter is denoted by two symbols the length of the message is doubled by putting it in cipher. The cipher can be improved by introducing after every (say) eleventh digit a non-significant digit. If this is done the recipient of the message must erase every twelfth digit before he begins to read the message. With this addition the difficulty of discovering the key is considerably increased. The same principle is sometimes applied with letters instead of numbers. For instance, if we take a word (say) of n letters, preferably all different, and construct a table as shown below of n 2 cells, each cell is defined by two letters of the key-word. Thus, if we choose the word smoking-cap we shall have 100 cells, and each cell is determined uniquely by the two letters denoting its row and column. If we fill these cells in order with the letters of the alphabet we shall have a system similar to that explained above, where a will be denoted by ss or og or no, and so for the other letters. The last 22 cells may be used to denote the first 22 letters of the alphabet, or better, three or four of them may be used after the end of a word to show

that it is ended, and the rest may be used to denote words or sentences which are likely CH. XI] CIPHERS 263 S M O K I N G C A P S a b c d e f g h i j M k l m n o p q r s t O u v w x y z a b c d K e f g h i j k l m n I o p q r s t u v w x N y z a b c d e f g h G i j k l m n o p q r C s t u v w x y z A P to occur frequently. Like the similar cipher with numbers this can be improved by introducing after every mth letter any single letter which it is agreed shall be non-significant. To decipher a communication so written it is necessary to know the clue-word and the clue-number. Here for instance is a communication written in the above cipher with the clue-word smoking-cap, and with 7 as the clue-number: ngmk sigrioicpssamckscakqignassnxmigpoasuiamnocmpaminscnogcpncisyiksk amsssgnncaekknoomkhscpcmscbgpngsiawssgiggndiica 1 . In this sentence the letters denoting the 79th, 80th, 81st, and 82nd cells have been used to denote the end of a word, and no use has been made of the last 18 cells. Another cipher of this type is made as follows* . The sender and recipient of the message furnish themselves with identical copies of some book. In the cipher only numerals are used, and these numerals indicate the locality of the letters in the book. For example, the first letter in the communication might be indicated by 79–8–5, meaning that it is the 5th letter in the 8th line of the 79th page. But though secrecy might * The method is well known. It is mentioned by E.A. Poe, Collected Works, vol. iii, pp. 338–9, but is much older. 1. The original text read . . . sssgnnn. . . , which leads to gobbledegook in the deciphered message. 264 CRYPTOGRAPHS AND CIPHERS. [CH. XI be secured, it would be very tedious to prepare or decode a message, and the method is not as safe as some of those described below. Another cipher of this type is for the sender and receiver to agree on some common book of reference and to agree further on a number which, if desired, may be communicated as part of the message. To employ this cipher the page of the book indicated by the given number must be used. The first letter in it is taken to signify a, the next b, and so on–any letter which occurs a second time or more frequently being neglected. It may be also arranged that after n letters of the message have been ciphered, the next n letters shall be written in a similar cipher taken from the pth following page of the book, and so on. Thus the possession of the code-book would be of little use to anyone who did not also know the numbers employed. It is so easy to conceal the clue number that with ordinary prudence it would be almost impossible for an unauthorized person to discover a message sent in this cipher. The clue number may be communicated indirectly in many ways. For instance, it may be arranged that the number to be used shall be the number sent, plus (say) q, or that the number to be used shall be an agreed multiple of the number actually sent. A cipher of the third type is one in which the same symbol represents sometimes one letter or word and sometimes another. Usually such ciphers are easily made or read by those who have the key, but are difficult to discover by those who do not possess it. A simple

example is the employment of pre-arranged numbers in shifting forward the letters that make the communication. For instance, if we agree on the clue number (say) 4276, then the first letter in the communication is replaced by the fourth letter which follows it in the natural order of the alphabet: for instance, if it were an a it would be replaced by e. The next letter is replaced by the second letter which follows it in the natural order of the alphabet: for instance, if it were an a it would be replaced by c. The next letter is replaced by the seventh after it. The next by the sixth after it. The next by the fourth, and so on to the end of the message. Of course to read the message the recipient would reverse the process. If the letters of the alphabet are written at uniform intervals along a ruler, and another ruler similarly marked with the digits can slide along it, the letter corresponding to the shifting of any given number of places can be read at once. It would be undesirable to allow the division into words to appear CH. XI] CIPHERS 265 in the message, and either the words must be run on continuously, or preferably the less common letters j, q, z may be used to mark the division of words. It is also well to conceal the number of digits in the clue-number. This can be done and the cipher much improved by inserting after every (say) mth letter a non-significant letter. Here for instance is a communication written in this cipher with the clue-numbers 4276 and 7: atpznhvaxuxhiepxafwghzniyprpsikbdkzy
ygkqprgezuytlkobldifebzmxlpogquyitcmgxkckuexvsqkaziaggsigaytnvvsstyv
uaslywgjuzmcsfctqbpwjvaepfxhibwpxiultxlavvtqzoxwkvtuvvfheqbxnpvismp hzmqtuwxjykeevltif . The recipient would begin by striking out every eighth letter. He would then shift back every letter 4, 2, 7, 6, 4, 2, &c., places respectively, and in reading it would leave out the letters j, q, and z as only marking the ends of words. This is an excellent cipher, and it has the additional merit of not materially lengthening the message. It can be rendered still more difficult by arranging that either or both the clue-numbers shall be changed according to some definite scheme, and it may be further agreed that they shall change automatically every day or week. A somewhat similar system was proposed by Wilkins* . He took a key-word, such as prudentia, and constructed as many alphabets as there were letters in it, each alphabet being arranged cyclically and beginning respectively with the letters p, r, u, d, e, n, t, i, and a. He thus got a table like the following, giving nine possible letters which might stand for any letter of the alphabet. Using this we may vary the cipher in successive words or letters of the communication. Thus a b c d e f g h i k l m n o p q r s t u v w x y z p q r s t u v w x y z a b c d e f g h i k l m n o r s t u v w x y z a b c d e f g h i k l m n o p q u v w x y z a b c d e f g h i k l m n o p q r s t d e f g h i k l m n o p q r s t u v w x y z a b c e f g h i k l m n o p q r s t u v w x y z a b c d n o p q r s t u v w x y z a b c d e f g h i k l m t u v w x y z a b c d e f g h i k l m n o P q r s i k l m n o p q r s t u v w x y z a b c d e f g h a b c d e f g h i k l m n o p q r s t u v w x y z * Mercury, by J. Wilkins, London, 1641, pp. 59, 60. 266 CRYPTOGRAPHS AND CIPHERS. [CH. XI the message

The prisoners have mutinied and seized the railway station would, according as the cipher changes in successive words or letters, read as Hwt fhziedvhi bupy pxwmqmhg erh ervmrq max zirteig station or as Hyy svvlwnthm lehx uukzgmiq tvd gvcciq mqe frcoanr atpkcrr. I have taken Wilkins's key-word, but it is obvious that it would be desirable to omit a wherever it appears in it, since otherwise, if the cipher changes in successive words, some of the words may appear unaltered in the cipher, as is shown in the first of the examples given above. A cipher of the fourth type is one in which each letter is always represented by the same symbol, but more than one letter may be represented by the same symbol. Such ciphers were not uncommon at the beginning of the nineteenth century, and were usually framed by means of a key-sentence containing about as many letters as there are letters in the alphabet. Thus if the key-phrase is The fox jumped over the garden gate, we write under it the letters of the alphabet in their usual sequence as shown below: T h e f o x j u m p e d o v e r t h e g a r d e n g a t e . a b c d e f g h i j k l m n o p q r s t u v w x y z a b c . Then we write the message replacing a by t or a, b by h or t, c by e, d by f, and so on. Here is such a message. M foemho nea ge eoo jmdhohg avf teg ev ume afrmeo. But it will be observed that in the cipher a may represent a or u, d may represent l or w, e may represent c or k or o or s or x, g may represent t or z, h may represent b or r, o may represent e or m, r may represent p or v, and t may represent a or b or q. And the recipient, in deciphering it, must judge as best he can which is the right meaning to be assigned to these letters when they appear. An instance of a cipher of the fourth type is afforded by a note sent by the Duchess de Berri to her adherents in Paris, in which she employed the key phrase l e g o u v e r n e m e n t p r o v i s o i r e. a b c d e f g h i j k l m n o p q r s t u v x y. Hence in putting her message into cipher she replaced a by l, b by e, c by g, and so on. She forgot however to supply the key to the recipients of the message, but her friend Berryer had little difficulty in reading it by the aid of the rules I have indicated, and thence deduced the key-phrase she had employed. CH. XI] CIPHERS 267 Having considered various classes of cryptographs and ciphers I may now consider what features we should regard as important in choosing a cipher intended for practical use. In the first place, it is obvious that the means employed should be such as not to excite suspicion if the communication falls into unauthorized hands. But this is a counsel of perfection, and almost impossible to attain. In the second place, we may say that, under modern conditions in war, finance, or diplomacy, a cipher may be useless unless it can be telegraphed or telephoned. If this is deemed important, it will practically restrict us to the use of the 26 letters of the alphabet, the 10 numerical symbols for the digits, to which if we like we may add a few additional marks such as punctuation stops, brackets, &c. The same condition will require that the message should not be unduly lengthened by being turned into cipher. Hence any considerable use of non-significant symbols is to be deprecated. In

the third place, the key to the cipher should be such that it can be easily reproduced from memory. For, if the key is so elaborate that those who use it are obliged to preserve it in some tangible and accessible form, unauthorized persons may obtain the power of reading messages. Hence the key should be reproducible at will. Further, it is desirable that the key should be of such a character that it (or a change of it) can be telegraphed or otherwise communicated without the probability of exciting suspicion. In the fourth place, a cipher should be capable of change at short intervals. So that if the reading of one message in it be discovered subsequent messages may be undecipherable even though the system used is unaltered. Lastly, no ambiguity should be possible in deciphering the communication. This will exclude ciphers of the fourth type. Accordingly in choosing a good cipher we should seek for one in which only current letters, symbols, or words are employed; such that its use does not unduly lengthen the message; such that the key to it can be reproduced at will and need not be kept in a form which might betray the secret to an unauthorized person; such that the key to it changes or can be changed at short intervals; and such that it is not ambiguous. Many ciphers of the second and third types fulfil these conditions, but it is generally desirable to avoid ciphers of the first type 268 CRYPTOGRAPHS AND CIPHERS. [CH. XI unless circumstances permit of the free use of a code-book. The use of instruments giving a cipher, which is or can be varied constantly and automatically, has been often recommended. Several have been constructed on the lines of the well-known letter-locks* . The possession of the key of the instrument as well as a knowledge of the clue-word is necessary to enable anyone to read a message, but the risk of some instrument, when set, falling into unauthorized hands must be taken into account. Since equally good ciphers can be constructed without the use of mechanical devices I do not think their employment can be recommended. This chapter has already run to such a length that I cannot find space to describe more than one or two ciphers that appear in history or fiction, but, we may say that until recently most of the historical ciphers are not difficult to read. It is said that Julius Caesar in making secret memoranda was accustomed to move every letter four places forward, writing d for a, e for b, &c. This would be a very easy instance of a cipher of the first type, but it may have been effective at that time. His nephew Augustus sometimes used a similar cipher, in which each letter was moved forward one place† . Bacon proposed a cipher in which each letter was denoted by a group of five letters consisting of A and B only. Since there are 32 such groups, he had 6 symbols to spare, which he could use to separate words or to which he could assign special meanings. A message in this cipher would be five times as long as the original message. This may be compared with the far superior system of the five (or four) digit codebook system in use at the present time. Charles I used ciphers freely in important correspondence—the majority being of the second type. He was foolish enough to take a

cabinet containing many confidential letters in cipher, to some of which their * See, for instance, the descriptions of those devised by Sir Charles Wheatstone, given in his Scientific Papers, London, 1879, pp. 342–347; and by Capt. Bazeries in Comptes Rendus, Association Français pour l'avancement des sciences, vol. xx (Marseilles), 1891, p. 160, et seq. † Of some of Caesar's correspondence, Suetonius says (cap. 56) si quis investigare et persequi velit, quartam elementorum literam, id est, d pro a, et perinde reliquas commutet. And of Augustus he says (cap. 88) quoties autem per notas scribit, b pro a, c pro b, ac deinceps eadem ratione, sequentes literas ponit; pro x autem duplex a. CH. XI] CIPHERS 269 readings were appended, on the field of Naseby, where they fell into the hands of Fairfax* . The House of Commons sent them to a committee presided over by a Mr Tate. It is commonly believed that the Committee referred the papers to J. Wallis† , then Fellow of Queens' College, Cambridge, and subsequently Savilian Professor at Oxford, who discovered the key to them. At any rate the letters were read. In these ciphers each letter was represented by a number. The clues to some of the ciphers were provided by the King who had written over the number the letter which it represented, as shown in the following quotation: c a t o l i c k s i n F 11 18 45 35 23 27 11 25 47 28 40 148 haue layed t h i r p u r s e s t o g e t h e r 45 31 27 51 33 62 50 47 7 48 45 35 21 7 46 32 7 51 f o r s u p l y of a r m e s. – – – 15 35 50 a 47 62 33 23 74 k1 17 51 42 7 47. – – – The published letters show that the King used different ciphers at different times, though perhaps he used the same one in all correspondence with any particular person, but the general character of those he employed is the same. The sentence quoted above is taken from a letter from Queen Henrietta Maria of January 26, 1643. In this and another letter a few months later a is represented by 17 or 18, b by 13, c by 11 or 12, d by 5, e by 7 or 8 or 9 or 10, f by 15 or 16, g by 21, h by 31 or 32, i by 27 or 28, k by 25, l by 23 or 24, m by 42 or 44, n by 39 or 40 or 41, o by 35 or 36 or 37 or 38, p by 33 or 34, r by 50 or 51 or 52, s by 47 or 48, t by 45 or 46, u by 62 or 63, w by 58, and y by 74 or 77. Numbers of three digits were used to represent particular people or places. Thus 148 stood for France, 189 for the King, 260 for the Queen, 354 for Prince Rupert, and so on. Further, there were a few special symbols, thus k1 stood for but, n1 for to, and f 1 for is. The numbers 2 to 4 and 65 to 72 were non-significant, and were to be struck out or neglected by the recipient of the message. Each symbol is separated from that which follows it by a full-stop. * First Report of the Royal Commission on Historical Manuscripts, 1870, pp. 2, 4. † See his letters on Cryptography, Opera, vol. iii, pp. 659–672. 270 CRYPTOGRAPHS AND CIPHERS. [CH. XI The Queen seems to have found writing in cipher a great trouble. In the letter from which I have already quoted a sentence she says . . . que je suis extrement tourmantee du mal de teete qui fait que je mesteray en syfre par un autre se qui jovois fait moy mesme, and she uses the cipher only for the particular words it was desired to conceal. Thus she writes Mr Capell nous a

fait voir que sy 27, 23, &c., &c. If by this she saved herself trouble, she did it at the cost of rendering the cipher much easier to read. The system used by Charles was in considerable repute during the seventeenth century, but even without extraneous help it is possible for a diligent student to discover the key if the message is fairly long. An excellent illustration of this fact is to be found in the writings of the late Sir Charles Wheatstone. A paper in cipher, every page of which was initialled by Charles I, and countersigned by Lord Digby, was purchased some years ago by the British Museum. It was believed to be a state paper of importance. It consists of a series of numbers (about 150 different symbols being used) without any clue to their meaning, or any indication of a division between the words employed. The task of reading it was rendered the more difficult by the supposition, which proved incorrect, that the document was in English; but notwithstanding this, Sir Charles Wheatstone discovered the key* . In this cipher a was represented by any of the numbers 12, 13, 14, 15, 16, or 17, b by 18 or 19, and so on, while some 65 special words were represented by particular numbers. I may note in passing that Charles also used a species of shorthand, in which the letters were represented by four strokes varying in length and position. Essentially the system is simple, though it is troublesome to read or write. The famous diary of Samuel Pepys is commonly said to have been written in cipher, but in reality it is written in shorthand according to a system invented by T. Shelton† . It is however somewhat difficult to read, for the vowels are usually omitted, and Pepys used some arbitrary signs for terminations, particles, and certain words—so far turning it into a cipher. Further, in certain places, when the matter * The document, its translation, and the key used are given in Wheatstone's Scientific Papers, London, 1879, pp. 321–341. † Tachy-graphy by T. Shelton. The earliest edition I have seen is dated 1641. A somewhat similar system by W. Cartwright was issued by J. Rich under the title Semographie, London, 1644. CH. XI] CIPHERS 271 is such that it can hardly be expressed with decency, he changed from English to a foreign language, or inserted non-significant letters. Shelton's system had been forgotten when attention was first attracted to the diary. Accordingly we may say that, to those who first tried to read it, it was written in cipher, but Pepys's contemporaries would have properly described it as being written in shorthand, though with a few modifications of his own invention. A system of shorthand specially invented for the purpose is a true cipher. One such system in which each letter is represented either by a dot or by a line of constant length was used by the Earl of Glamorgan, better known by his subsequent title as Marquis of Worcester, in 1645, as also by Charles I. in some of his private correspondence. It is a cipher of the first type and has the defects inherent in almost every cipher of this kind: in fact Glamorgan's letter was deciphered, and the system discovered by Mr Dircks* . Obsolete systems of shorthand† might be thus used to form an effective cipher. It is always difficult to read a very short message in cipher, since

necessarily the clues are few in number. When the Chevalier de Rohan was sent to the Bastille, on suspicion of treason, there was no evidence against him except what might be extracted from Monsieur Latruaumont. The latter died without making any admission. De Rohan's friends had arranged with him to communicate the result of Latruaumont's examination, and accordingly in sending him some fresh body linen they wrote on one of the shirts Mg dulhxcclgu ghj yxuj, lm ct ulgc alj. For twenty-four hours de Rohan pored over the message, but, failing to read it, he admitted his guilt, and was executed November 27, 1674. The cipher is a very simple one of the first type, but the communication is so short that unless the key were known it would not be easy to read it. Had de Rohan suspected that the second word was prisonnier, it would have given him 7 out of the 12 letters used, and as the first and third words suggest the symbols used for l and t, he could hardly have failed to read the message. * Life of the Marquis of Worcester by H. Dircks, London, 1865. Worcester's system of shorthand was described by him in his Century of Inventions, London, 1663, sections 3, 4, 5. † Various systems, including those used in classical and medieval times, are described in the History of Shorthand by T. Anderson, London, 1882. 272 CRYPTOGRAPHS AND CIPHERS. [CH. XI The following cipher is said to have been employed by Marie Antoinette* . I take it that it was used in the method indicated on page 265 AB A O B P C Q D R E S F T G V H X I Y L Z M N CD M Z A N B O C P D Q E R F S G T H V I X L Y EF L N M O A P B Q C R D S E T F V G X H Y I Z GH I N L O M P A Q B R C S D T E V F X G Y H Z IL H N I O L P M Q A R B S C T D V E X F Y G Z MN G N H O I P L Q M R A S B T C V D X E Y F Z OP F N G O H P I Q L R M S A T B V C X D Y E Z QR E N F O G P H Q I R L S M T A V B X C Y D Z ST D N E O F P G Q H R I S L T M V A X B Y C Z VX C N D O E P F Q G R H S I T L V M X A Y B Z YZ B N C O D P E Q F R G S H T I V L X M Y A Z above. If so, the first word in the communication would be rewritten according to the scheme given in the first line, a being replaced by o, and vice versâ, b by p, and so on. The second word would be rewritten according to the scheme in the second line, and so on. * The key is given, but without explanation, in Juniper Hall, by C. Hill, London, 1904, p. 13. CH. XI] CIPHERS 273 One of the modern systems is the five digit code-book cipher, to which I have already alluded. According to the general belief, it is frequently employed in certain official communications at the present day. A code dictionary is prepared in which every word likely to be used is printed, and the words are numbered consecutively 00000, 00001, . . . up, if necessary, to 99999. Thus each word is represented by a number of five digits, and there are 105 such numbers available. The message is first written down in words. Below that it is written in numbers, each word being replaced by the number corresponding to it. To each of these numbers is added some definite prearranged clue-number— the words in the dictionary being assumed to be arranged cyclically, so that if the resulting number exceeds 105 it is denoted only by the excess above 105 . The resulting numbers are sent as a message. On receipt

of a message it is divided into consecutive groups of five numbers, each group representing a word. From each number is subtracted the prearranged clue-number, and then the message can be read off by the code dictionary. When a code message is published by the Government receiving it, the construction of the sentences is usually altered before publication, so that the key may not be discoverable by anyone in possession of the code-book or who has seen the cipher message. This is a rule applicable to all cryptographs and ciphers. This is a cipher with 105 symbols, and as each symbol consists of five digits, a message of n words is denoted by 5n digits, and probably is not longer than the message when written in the ordinary way. Since however the number of words required is less than 105 , the spare numbers may be used to represent collocations of words which constantly occur, and if so the cipher message may be slightly shortened. If the clue number is the same all through the message it would be possible by not more than 105 trials to discover the message. This is not a serious risk, but, slight though it is, it can be avoided if the clue number is varied; the clue number might, for instance, be 781 for the first three words, 791 for the next five words, 801 for the next seven words, and so on. Further it may be arranged that the clue numbers shall be changed every day; thus on the seventh day of the month they might be 781, 791, &c., and on the eighth day 881, 891, &c., and so on. This cipher can however be further improved by inserting at some step, say after each mth digit, an unmeaning digit. For example, if, in the original message written in numbers, we insert a 9 after every 274 CRYPTOGRAPHS AND CIPHERS. [CH. XI seven digits we shall get a collection of words (each represented by five digits), most of which would have no connection with the original message, and probably the number of digits used in the message itself would no longer be a multiple of 5. Of course the receiver has only to reverse the process in order to read the message. It is however unnecessary to use five symbols for each word. For if we make a similar code with the twenty-six letters of the alphabet instead of the ten digits, four letters for each word or phrase would give us 264 , that is, 456976 possible variations. Thus the message would be shorter and the power of the code increased. Further, if we like to use the ten digits and the twenty-six letters of the alphabet—all of which are easily telegraphed—we could, by only using three symbols, obtain 363 , that is, 46656 possible words, which would be sufficient for all practical purposes. This code, at any rate with these modifications, is undecipherable by strangers, but it has the disadvantages that those who use it must always have the code dictionary available, and that it takes a considerable time to code or decode a communication. For practical purposes its use would be confined to communications which could be deciphered at leisure in an office, It is especially suitable in the case of communications between officials, each supplied with a competent staff of secretaries or clerks—as from an ambassador to his chief, or a commander in the field to his war office. It is an excellent example

of a cipher of the first type, but it is not clear that it possesses any superiority over some of the simple ciphers of the third type. One of the best known writers on the subject of cryptographs and ciphers is E.A. Poe, indeed probably a good many readers have made their first acquaintance with a cipher in his story of The Gold Bug, the interest of which turns on reading a simple cipher of the first type. In earlier times J. Tritheim of Spanheim, G. Porta of Naples, Cardan, Niceron, and J. Wilkins occupied much the same position, while whenever ciphers were freely used skilful decipherers seem to have arisen. Poe wrote an essay on cryptography in which he said that it may be roundly asserted that human ingenuity cannot concoct a cipher which human ingenuity cannot resolve—a conclusion which is hardly justified by the known facts. In an earlier article he once made a similar remark so far as ciphers of the first class are concerned, with the implied limitation that only 26 symbols may be used. In this sense the observation is correct. His assertion excited some attention, and numerous CH. XI] CIPHERS 275 communications in cipher were sent to him. More than one of his correspondents did not play the game fairly, not only employing foreign languages, but using several different ciphers in the same communication. Nevertheless he resolved all except one; and he proved that this last was a fraud, being merely a jargon of random characters, having no meaning whatever. CHAPTER XII. HYPER-SPACE† . I propose to devote the remaining pages to the consideration, from the point of view of a mathematician, of certain properties of space, time, and matter, and to a sketch of some hypotheses as to their nature. I shall not discuss the metaphysical theories that profess to † On the possibility of the existence of space of more than three dimensions see C.H. Hinton, Scientific Romances, London, 1886, a most interesting work, from which I have derived much assistance in compiling the earlier part of this chapter; his later work, The Fourth Dimension, London, 1904, may be also consulted. See also G.F. Rodwell, Nature, May 1, 1873, vol. viii, pp. 8, 9; and E.A. Abbott, Flatland, London, 1884. The theory of Non-Euclidean geometry is due primarily to Lobatschewsky, Geometrische Untersuchungen zur Theorie der Parallellinien, Berlin, 1840 (originally given in a lecture in 1826); to Gauss (ex. gr. letters to Schumacher, May 17, 1831, July 12, 1831, and Nov. 28, 1846, printed in Gauss's collected works); and to J. Bolyai, Appendix to the first volume of his father's Tentamen, MarosVásárkely, 1832; though the subject had been discussed by J. Saccheri as long ago as 1733: its development was mainly the work of G.F.B. Riemann, Ueber die Hypothesen welche der Geometrie zu Grunde liegen, written in 1854, Göttinger Abhandlungen, 1866–7, vol. xiii, pp. 131–152 (translated in Nature, May 1 and 8, 1873, vol. viii, pp. 14–17, 36–37); H.L.F. von Helmholtz, Göttinger Nachrichten, June 3, 1868, pp. 193–221; and E. Beltrami, Saggio di Interpretazione della Geometria non-Euclidea, Naples, 1868, and the Annali di Matematica, series 2, vol. ii, pp. 232–255: see an article by von Helmholtz in the Academy, Feb. 12, 1870, vol. i, pp.

128–131. Within the last twenty-five years the theory has been treated by several mathematicians. A bibliography of hyper-space, compiled by G.B. Halsted, appeared in the American Journal of Mathematics, vol. i (1878), pp. 261–276, 384–385; and vol. ii (1879), pp. 65–70. 276 CH. XII] HYPER-SPACE. 277 account for the origin of our conceptions of them, for these theories lead to no practical result and rest on assertions which are incapable of definite proof—a foundation which does not commend itself to a scientific student. Space, time, and matter cannot be defined; but the means of measuring them and the investigation of their properties fall within the domain of mathematics. I devote this chapter to considerations connected with space, leaving the subjects of time and mass to the following two chapters. I shall confine my remarks on the properties of space to two speculations which recently have attracted considerable attention. These are (i) the possibility of the existence of space of more than three dimensions, and (ii) the possibility of kinds of geometry, especially of two dimensions, other than those which are treated in the usual text-books. These problems are related. The term hyper-space was used originally of space of more than three dimensions, but now it is often employed to denote also any Non-Euclidean space. I attach the wider meaning to it, and it is in that sense that this chapter is on the subject of hyper-space. In regard to the first of these questions, the conception of a world of more than three dimensions is facilitated by the fact that there is no difficulty in imagining a world confined to only two dimensions—which we may take for simplicity to be a plane, though equally well it might be a spherical or other surface. We may picture the inhabitants of flatland as moving either on the surface of a plane or between two parallel and adjacent planes. They could move in any direction along the plane, but they could not move perpendicularly to it, and would have no consciousness that such a motion was possible. We may suppose them to have no thickness, in which case they would be mere geometrical abstractions: or, preferably, we may think of them as having a small but uniform thickness, in which case they would be realities. Several writers have amused themselves by expounding and illustrating the conditions of life in such a world. To take a very simple instance, in flatland—or any even dimensional space—a knot is impossible, a simple alteration which alone would make some difference in the experience of the inhabitants as compared with our own. If an inhabitant of flatland was able to move in three dimensions, he would be credited with supernatural powers by those who were unable so to move; for he could appear or disappear at will, could (so far as they could tell) create matter or destroy it, and would be free from so 278 HYPER-SPACE. [CH. XII many constraints to which the other inhabitants were subject that his actions would be inexplicable by them. We may go one step lower, and conceive of a world of one dimension—like a long tube—in which the inhabitants could move only forwards and backwards. In such a universe there would be lines of varying

lengths, but there could be no geometrical figures. To those who are familiar with space of higher dimensions, life in line-land would seem somewhat dull. It is commonly said that an inhabitant could know only two other individuals; namely, his neighbours, one on each side. If the tube in which he lived was itself of only one dimension, this is true; but we can conceive an arrangement of tubes in two or three dimensions, where an occupant would be conscious of motion in only one dimension, and yet which would permit of more variety in the number of his acquaintances and conditions of existence. Our conscious life is in three dimensions, and naturally the idea occurs whether there may not be a fourth dimension. No inhabitant of flatland could realize what life in three dimensions would mean, though, if he evolved an analytical geometry applicable to the world in which he lived, he might be able to extend it so as to obtain results true of that world in three dimensions which would be to him unknown and inconceivable. Similarly we cannot realize what life in four dimensions is like, though we can use analytical geometry to obtain results true of that world, or even of worlds of higher dimensions. Moreover the analogy of our position to the inhabitants of flatland enables us to form some idea of how inhabitants of space of four dimensions would regard us. Just as the inhabitants of flatland might be conceived as being either mere geometrical abstractions, or real and of a uniform thickness in the third dimension, so, if there is a fourth dimension, we may be regarded either as having no thickness in that dimension, in which event we are mere (geometrical) abstractions—as indeed idealist philosophers have asserted to be the case—or as having a uniform thickness in that dimension, in which event we are living in four dimensions although we are not conscious of it. In the latter case it is reasonable to suppose that the thickness in the fourth dimension of bodies in our world is small and possibly constant; it has been conjectured also that it is comparable with the other dimensions of the molecules of matter, and if so it is possible that the constitution of matter and its fundamental properties may supply experimental data which will give a physical CH. XII] HYPER-SPACE. 279 basis for proving or disproving the existence of this fourth dimension. If we could look down on the inhabitants of flatland we could see their anatomy and what was happening inside them. Similarly an inhabitant of four-dimensional space could see inside us. An inhabitant of flatland could get out of a room, such as a rectangle, only through some opening, but, if for a moment he could step into three dimensions, he could reappear on the other side of any boundaries placed to retain him. Similarly, if we came across persons who could move out of a closed prison-cell without going through any of the openings in it, there might be some reason for thinking that they did it by passing first in the direction of the fourth dimension and then back again into our space. This however is unknown. Again, if a finite solid was passed slowly through flatland, the inhabitants would be conscious only of that part of it which was in their plane. Thus they would see the shape of the

object gradually change and ultimately vanish. In the same way, if a body of four dimensions was passed through our space, we should be conscious of it only as a solid body, namely, the section of the body by our space, whose form and appearance gradually changed and perhaps ultimately vanished. It has been suggested that the birth, growth, life, and death of animals may be explained thus as the passage of finite four-dimensional bodies through our three-dimensional space. I believe that this idea is due to Mr Hinton. The same argument is applicable to all material bodies. The impenetrability and inertia of matter are necessary consequences; the conservation of energy follows, provided that the velocity with which the bodies move in the fourth dimension is properly chosen: but the indestructibility of matter rests on the assumption that the body does not pass completely through our space. I omit the details connected with change of density as the size of the section by our space varies. We cannot prove the existence of space of four dimensions, but it is interesting to enquire whether it is probable that such space actually exists. To discuss this, first let us consider how an inhabitant of flatland might find arguments to support the view that space of three dimensions existed, and then let us see whether analogous arguments apply to our world. I commence with considerations based on geometry and then proceed to those founded on physics. 280 HYPER-SPACE. [CH. XII Inhabitants of flatland would find that they could have two triangles of which the elements were equal, element to element, and yet which could not be superposed. We know that the explanation of this fact is that, in order to superpose them, one of the triangles would have to be turned over so that its undersurface came on to the upper side, but of course such a movement would be to them inconceivable. Possibly however they might have suspected it by noticing that inhabitants of one-dimensional space might experience a similar difficulty in comparing the equality of two lines, ABC and CB'A' , each defined by a set of three points. We may suppose that the lines are equal and such that corresponding points in them could be superposed by rotation round C—a movement inconceivable to the inhabitants—but an inhabitant of such a world in moving along from A to A' would not arrive at the corresponding points in the two lines in the same relative order, and thus might hesitate to believe that they were equal. Hence inhabitants of flatland might infer by analogy that by turning one of the triangles over through three-dimensional space they could make them coincide. We have a somewhat similar difficulty in our geometry. We can construct triangles in three dimensions—such as two spherical triangles— whose elements are equal respectively one to the other, but which cannot be superposed. Similarly we may have two spirals whose elements are equal respectively, one having a right-handed twist and the other a left-handed twist, but it is impossible to make one fill exactly the same parts of space as the other does. Again, we may conceive of two solids, such as a right hand and a left hand, which are exactly similar and equal but of which one cannot be

made to occupy exactly the same position in space as the other does. Those are difficulties similar to those which would be experienced by the inhabitants of flatland in comparing triangles; and it may be conjectured that in the same way as such difficulties in the geometry of an inhabitant in space of one dimension are explicable by temporarily moving the figure into space of two dimensions by means of a rotation round a point, and as such difficulties in the geometry of flatland are explicable by temporarily moving the figure into space of three dimensions by means of a rotation round a line, so such difficulties in our geometry would disappear if we could temporarily move our figures into space of four dimensions by means of a rotation round a plane—a movement which of course is inconceivable to us. CH. XII] HYPER-SPACE. 281 Next we may enquire whether the hypothesis of our existence in a space of four dimensions affords an explanation of any difficulties or apparent inconsistencies in our physical science* . The current conception of the luminiferous ether, the explanation of gravity, and the fact that there are only a finite number of kinds of matter, all the atoms of each kind being similar, present such difficulties and inconsistencies. To see whether the hypothesis of a four-dimensional space gives any aid to their elucidation, we shall do best to consider first the analogous problems in two dimensions. We live on a solid body, which is nearly spherical, and which moves round the sun under an attraction directed to it. To realize a corresponding life in flatland we must suppose that the inhabitants live on the rim of a (planetary) disc which rotates round another (solar) disc under an attraction directed towards it. We may suppose that the planetary world thus formed rests on a smooth plane, or other surface of constant curvature; but the pressure on this plane and even its existence would be unknown to the inhabitants, though they would be conscious of their attraction to the centre of the disc on which they lived. Of course they would be also aware of the bodies, solid, liquid, or gaseous, which were on its rim, or on such points of its interior as they could reach. Every particle of matter in such a world would rest on this plane medium. Hence, if any particle was set vibrating, it would give up a part of its motion to the supporting plane. The vibrations thus caused in the plane would spread out in all directions, and the plane would communicate vibrations to any other particles resting on it. Thus any form of energy caused by vibrations, such as light, radiant heat, electricity, and possibly attraction, could be transmitted from one point to another without the presence of any intervening medium which the inhabitants could detect. If the particles were supported on a uniform elastic plane film, the intensity of the disturbance at any other point would vary inversely as the distance of the point from the source of disturbance; if on a uniform elastic solid medium, it would vary inversely as the square of that distance. But, if the supporting medium was vibrating, then, * See a note by myself in the Messenger of Mathematics, Cambridge, 1891, vol. xxi, pp. 20–24, from which the above argument is extracted. The question has

been treated by Mr Hinton on similar lines. 282 HYPER-SPACE. [CH. XII wherever a particle rested on it, some of the energy in the plane would be given up to that particle, and thus the vibrations of the intervening medium would be hindered when it was associated with matter. If the inhabitants of this two-dimensional world were sufficiently intelligent to reason about the manner in which energy was transmitted they would be landed in a difficulty. Possibly they might be unable to explain gravitation between two particles—and therefore between the solar disc and their disc—except by supposing vibrations in a rigid medium between the two particles or discs. Again, they might be able to detect that radiant light and heat, such as the solar light and heat, were transmitted by vibrations transverse to the direction from which they came, though they could realize only such vibrations as were in their plane, and they might determine experimentally that in order to transmit such vibrations a medium of great rigidity (which we may call ether) was necessary. Yet in both the above cases they would have also distinct evidence that there was no medium capable of resisting motion in the space around them, or between their disc and the solar disc. The explanation of these conflicting results lies in the fact that their universe was supported by a plane, of which they were necessarily unconscious, and that this rigid elastic plane was the ether which transmitted the vibrations. Now suppose that the bodies in our universe have a uniform thickness in the fourth dimension, and that in that direction our universe rests on a homogeneous elastic body whose thickness in that direction is small and constant. The transmission of force and radiant energy, without the intervention of an intervening medium, may be explained by the vibrations of the supporting space, even though the vibrations are not themselves in the fourth dimension. Also we should find, as in fact we do, that the vibrations of the luminiferous ether are hindered when it is associated with matter. I have assumed that the thickness of the supporting space is small and uniform, because then the intensity of the energy transmitted from a source to any point would vary inversely as the square of the distance, as is the case; whereas if the supporting space was a body of four dimensions, the law would be that of the inverse cube of the distance. The application of this hypothesis to the third difficulty mentioned above—namely, to show why there are in our universe only a finite number of kinds of atoms, all the atoms of each kind having in common CH. XII] HYPER-SPACE. 283 a number of sharply defined properties—will be given later* . Thus the assumption of the existence of a four-dimensional homogeneous elastic body on which our three-dimensional universe rests, affords an explanation of some difficulties in our physical science. It may be thought that it is hopeless to try to realize a figure in four dimensions. Nevertheless attempts have been made to see what the sections of such a figure would look like. If the boundary of a solid is $\phi(x, y, z) = 0$, we can obtain some idea of its form by taking a series of plane sections by planes parallel to $z = 0$, and

mentally superposing them. In four dimensions the boundary of a body would be $\phi(x, y, z, \omega) = 0$, and attempts have been made to realize the form of such a body by making models of a series of solids in three dimensions formed by sections parallel to $\omega = 0$. Again, we can represent a solid in perspective by taking sections by three co-ordinate planes. In the case of a four-dimensional body the section by each of the four co-ordinate solids will be a solid, and attempts have been made by drawing these to get an idea of the form of the body. Of course a four-dimensional body will be bounded by solids. The possible forms of regular bodies in four dimensions, analogous to polyhedrons in space of three dimensions, have been discussed by Mr Stringham† . I now turn to the second of the two problems mentioned at the beginning of the chapter: namely, the possibility of there being kinds of geometry other than those which are treated in the usual elementary text-books. This subject is so technical that in a book of this nature I can do little more than give a sketch of the argument on which the idea is based. The Euclidean system of geometry, with which alone most people are acquainted, rests on a number of independent axioms and postulates. Those which are necessary for Euclid's geometry have, within recent years, been investigated and scheduled. They include not only those explicitly given by him, but some others which he unconsciously used. If these are varied, or other axioms are assumed, we get a different series of propositions, and any consistent body of such propositions * See below, p. 317 (3). † American Journal of Mathematics, 1880, vol. iii, pp. 1–14. 284 HYPER-SPACE. [CH. XII constitutes a system of geometry. Hence there is no limit to the number of possible Non-Euclidean geometries that can be constructed. Among Euclid's axioms and postulates is one on parallel lines, which is usually stated in the form that if a straight line meets two straight lines, so as to make the two interior angles on the same side of it taken together less than two right angles, then these straight lines being continually produced will at length meet upon that side on which are the angles which are less than two right angles. Expressed in this form the axiom is far from obvious, and from early times numerous attempts have been made to prove it* . All such attempts failed, and it is now known that the axiom cannot be deduced from the other axioms assumed by Euclid. It can be replaced by other statements about parallel lines, such as that the distance between two parallel lines is always the same, but such alternative statements, though perhaps primâ facie more axiomatic, are not to be preferred to Euclid's form, since his statement brings out prominently a characteristic feature of the space with which he is concerned. The earliest conception of a body of Non-Euclidean geometry was due to the discovery, made independently by Saccheri, Lobatschewsky, and John Bolyai, that a consistent system of geometry of two dimensions can be produced on the assumption that the axiom on parallels is not true, and that through a point a number of straight (that is, geodetic) lines can be drawn parallel to a given straight line. The resulting geometry

is called hyperbolic. Riemann later distinguished between boundlessness of space and its infinity, and showed that another consistent system of geometry of two dimensions can be constructed in which all straight lines are of a finite length, so that a particle moving along a straight line will return to its original position. This leads to a geometry of two dimensions, called elliptic geometry, analogous to the hyperbolic geometry, but characterized by the fact that through a point no straight line can be drawn which, if produced far enough, will not meet any other given straight line. This can be compared with the geometry of figures drawn on the surface of a sphere. Thus according as no straight line, or only one straight line, or a pencil of straight lines can be drawn through a point parallel to a given * Some of the more interesting and plausible attempts have been collected by J. Richard in his Philosophie de Mathématiques, Paris, 1903. CH. XII] HYPER-SPACE. 285 straight line, we have three systems of geometry of two dimensions known respectively as elliptic, parabolic or homaloidal or Euclidean, and hyperbolic. In the parabolic and hyperbolic systems straight lines are infinitely long. In the elliptic they are finite. In the hyperbolic system there are no similar figures of unequal size; the area of a triangle can be deduced from the sum of its angles, which is always less than two right angles; and there is a finite maximum to the area of a triangle. In the elliptic system all straight lines are of the same finite length; any two lines intersect; and the sum of the angles of a triangle is greater than two right angles. In the elliptic system it is possible to get from one point to a point on the other side of a plane without passing through the plane, namely, by going the other way round the straight line joining the two points; thus a watch-dial moving face upwards continuously forward in a plane in a straight line in the direction from the mark vi to the mark xii will finally appear to a stationary observer with its face downwards; and if originally the mark iii was to the right of the observer it will finally be on his left hand. In spite of these and other peculiarities of hyperbolic and elliptical geometries, it is impossible to prove by observation that one of them is not true of the space in which we live. For in measurements in each of these geometries we must have a unit of distance; and if we live in a space whose properties are those of either of these geometries, and such that the greatest distances with which we are acquainted (ex. gr. the distances of the fixed stars) are immensely smaller than any unit, natural to the system, then it may be impossible for our observations to detect the discrepancies between the three geometries. It might indeed be possible by observations of the parallaxes of stars to prove that the parabolic system and either the hyperbolic or elliptic system were false, but never can it be proved by measurements that Euclidean geometry is true. Similar difficulties might arise in connection with excessively minute quantities. In short, though the results of Euclidean geometry are more exact than present experiments can verify for finite things, such as those with which we have to deal, yet for much larger things or much

smaller things or for parts of space at present inaccessible to us they may not be true. If however we go a step further and ask what is meant by saying that a geometry is true or false, I can only quote the remark of Poincaré, 286 HYPER-SPACE. [CH. XII that the selection of a geometry is really a matter of convenience, and that that geometry is the best which enables us to state the physical laws in the simplest form. This opinion has been strongly controverted, but at any rate it expresses one view of the question. The above refers only to hyper-space of two dimensions. Naturally there arises the question whether there are different kinds of NonEuclidean space of three or more dimensions. Riemann showed that there are three kinds of Non-Euclidean space of three dimensions having properties analogous to the three kinds of Non-Euclidean space of two dimensions already discussed. These are differentiated by the test whether at every point no geodetical surface, or one geodetical surface, or a fasciculus of geodetical surfaces can be drawn parallel to a given surface: a geodetical surface being defined as such that every geodetic line joining two points on it lies wholly on the surface. It may be added that each of the three systems of geometry of two dimensions described above may be deduced as properties of a surface in each of these three kinds of Non-Euclidean space of three dimensions. It is evident that the properties of Non-Euclidean space of three dimensions are deducible only by the aid of mathematics, and cannot be illustrated materially, for in order to realize or construct surfaces in Non-Euclidean space of two dimensions we think of or use models in space of three dimensions; similarly the only way in which we could construct models illustrating Non-Euclidean space of three dimensions would be by utilizing space of four dimensions. We may proceed yet further and conceive of Non-Euclidean geometries of more than three dimensions, but this remains, as yet, an unworked field. Returning to the former question of Non-Euclidean geometries, I wish again to emphasize the fact that, if the axioms enunciated by Euclid are replaced by others, it is possible to construct other consistent systems of geometry. Some of these are interesting, but those which have been mentioned above have a special importance, from the somewhat sensational fact that they lead to no results necessarily inconsistent with the properties, as far as we can observe them, of the space in which we live; we are not at present acquainted with any other systems which are consistent with our experience. CHAPTER XIII. TIME AND ITS MEASUREMENT. The problems connected with time are totally different in character from those concerning space which I discussed in the last chapter. I there stated that the life of people living in space of one dimension would be uninteresting, and that probably they would find it impossible to realize life in space of higher dimensions. In questions connected with time we find ourselves in a somewhat similar position. Mentally, we can realize a past and a future—thus going backwards and forwards— actually we go only forwards. Hence time is analogous to space of one dimension. Were our

time of two dimensions, the conditions of our life would be infinitely varied, but we can form no conception of what such a phrase means, and I do not think that any attempts have been made to work it out. I shall concern myself here mainly with questions concerning the measurement of time, and shall treat them rather from a historical than from a philosophical point of view. In order to measure anything we must have an unalterable unit of the same kind, and we must be able to determine how often that unit is contained in the quantity to be measured. Hence only those things can be measured which are capable of addition to things of the same kind. Thus to measure a length we may take a foot-rule, and by applying it to the given length as often as is necessary, we shall find how many feet the length contains. But in comparing lengths we assume as the result of experience that the length of the foot-rule is constant, or rather that any alteration in it can be determined; and, if this assumption was denied, we could not prove it, though, if numerous repetitions of 287 288 TIME AND ITS MEASUREMENT. [CH. XIII the experiment under varying conditions always gave the same result, probably we should feel no doubt as to the correctness of our method. It is evident that the measurement of time is a more difficult matter. We cannot keep a unit by us in the same way as we can keep a footrule; nor can we repeat the measurement over and over again, for time once passed is gone for ever. Hence we cannot appeal directly to our sensations to justify our measurement. Thus, if we say that a certain duration is four hours, it is only by a process of reasoning that we can show that each of the hours is of the same duration. The establishment of a scientific unit for measuring durations has been a long and slow affair. The process seems to have been as follows. Originally man observed that certain natural phenomena recurred after the interval of a day, say from sunrise to sunrise. Experience—for example, the amount of work that could be done in it—showed that the length of every day was about the same, and, assuming that this was accurately so, man had a unit by which he could measure durations. The present subdivision of a day into hours, minutes, and seconds is artificial, and apparently is derived from the Babylonians. Similarly a month and a year are natural units of time though it is not easy to determine precisely their beginnings and endings. So long as men were concerned merely with durations which were exact multiples of these units or which needed only a rough estimate, this did very well; but as soon as they tried to compare the different units or to estimate durations measured by part of a unit they found difficulties. In particular it cannot have been long before it was noticed that the duration of the same day differed in different places, and that even at the same place different days differed in duration at different times of the year, and thus that the duration of a day was not an invariable unit. The question then arises as to whether we can find a fixed unit by which a duration can be measured, and whether we have any assurance that the seconds and minutes used to-day for that purpose are all

of equal duration. To answer this we must see how a mathematician would define a unit of time. Probably he would say that experience leads us to believe that, if a rigid body is set moving in a straight line without any external force acting on it, it will go on moving in that line; and those times are taken to be equal in which it passes over equal spaces: similarly, if it is set rotating about a principal axis passing CH. XIII] TIME AND ITS MEASUREMENT. 289 through its centre of mass, those times are taken to be equal in which it turns through equal angles. Our experiences are consistent with this statement, and that is as high an authority as a mathematician hopes to get. The spaces and the angles can be measured, and thus durations can be compared. Now the earth may be taken roughly as a rigid body rotating about a principal axis passing through its centre of mass, and subject to no external forces affecting its rotation: hence the time it takes to turn through four right angles, i.e. through 360◦ , is always the same; this is called a sidereal day: the time to turn through one twenty-fourth part of 360◦ , i.e. through 15◦ , is an hour: the time to turn through one-sixtieth part of 15◦ , i.e. through 15’ , is a minute: and so on. If, by the progress of astronomical research, we find that there are external forces affecting the rotation of the earth, mathematics would have to be invoked to find what the time of rotation would be if those forces ceased to act, and this would give us a correction to be applied to the unit chosen. In the same way we may say that although an increase of temperature affects the length of a foot-rule, yet its change of length can be determined, and thus applied as a correction to the foot-rule when it is used as the unit of length. As a matter of fact there is reason to think that the earth takes about one sixty-sixth of a second longer to turn through four right angles now than it did 2500 years ago, and thus the duration of a second is just a trifle longer today than was the case when the Romans were laying the foundations of the power of their city. The sidereal day can be determined only by refined astronomical observations and is not a unit suitable for ordinary purposes. The relations of civil life depend mainly on the sun, and he is our natural time keeper. The true solar day is the time occupied by the earth in making one revolution on its axis relative to the sun; it is true noon when the sun is on the meridian. Owing to the motion of the sun relative to the earth, the true solar day is about four minutes longer than a sidereal day. The true solar day is not however always of the same duration. This is inconvenient if we measure time by clocks (as now for nearly two centuries has been usual in Western Europe) and not by sun-dials, and therefore we take the average duration of the true solar day as the measure of a day: this is called the mean solar day. Moreover 290 TIME AND ITS MEASUREMENT. [CH. XIII to define the noon of a mean solar day we suppose a point to move uniformly round the ecliptic coinciding with the sun at each apse, and further we suppose a fictitious sun, called the mean sun, to move in the celestial equator so that its distance from the first point of Aries is the same as that of this

point: it is mean noon when this mean sun is on the meridian. The mean solar day is divided into hours, minutes, and seconds; and these are the usual units of time in civil life. The time indicated by our clocks and watches is mean solar time; that marked on ordinary sun-dials is true solar time. The difference between them is the equation of time: this may amount at some periods of the year to a little more than a quarter of an hour. In England we take the Greenwich meridian as our origin for longitudes, and instead of local mean solar time we take Greenwich mean solar time as the civil standard. Of course mean time is a comparatively recent invention. The French were the last civilized nation to abandon the use of true time: this was in 1816. Formerly there was no common agreement as to when the day began. In parts of ancient Greece and in Japan the interval from sunrise to sunset was divided into 12 hours, and that from sunset to sunrise into 12 hours. The Jews, Chinese, Athenians, and, for a long time, the Italians, divided their day into 24 hours, beginning at the hour of sunset, which of course varies every day: this method is said to be still used in certain villages near Naples, except that the day begins half-an-hour after sunset—the clocks being re-set once a week. Similarly the Babylonians, Assyrians, Persians, and until recently the modern Greeks and the inhabitants of the Balearic Islands counted the twenty-four hours of the day from sunrise. Until the middle of last century, the inhabitants of Basle reckoned the twenty-four hours from our 11.0 p.m. The ancient Egyptians and Ptolemy counted the twenty-four hours from noon: this is the practice of modern astronomers. In Western Europe the day is taken to begin at midnight—as was first suggested by Hipparchus—and is divided into two equal periods of twelve hours each. The week of seven days is an artificial unit of time. It had its origin in the East, and was introduced into the West by the Roman emperors, and, except during the French Revolution, has been subsequently in general use among civilized races. The names of the days are derived from the seven astrological planets, arranged, as was customary, CH. XIII] TIME AND ITS MEASUREMENT. 291 in the order of their apparent times of rotation round the earth, namely, Saturn, Jupiter, Mars, the Sun, Venus, Mercury, and the Moon. The twenty-four hours of the day were dedicated successively to these planets: and the day was consecrated to the planet of the first hour. Thus if the first hour was dedicated to Saturn, the second would be dedicated to Jupiter, and so on; but the day would be Saturn’s day. The twenty-fourth hour of Saturn’s day would be dedicated to Mars, thus the first hour of the next day would belong to the Sun; and the day would be Sun’s day. Similarly the next day would be Moon’s day; the next, Mars’s day; the next, Mercury’s day: the next, Jupiter’s day; and the next, Venus’s day. The astronomical month is a natural unit of time depending on the motion of the moon, and containing about 29 1 2 days. The months of the calendar have been evolved gradually as convenient divisions of time, and their history is given in numerous astronomies. In the original Julian arrangement the months

in a leap year contained alternately 31 and 30 days, while in other years February had 29 days. This was altered by Augustus in order that his month should not be inferior to one named after his uncle. The solar tropical year is another natural unit of time. According to a recent determination, it contains 365.242216 days, that is, 365d. 5 h. 48m. 47s..4624. The Egyptians knew that it contained between 365 and 366 days, but the Romans did not profit by this information, for Numa is said to have reckoned 355 days as constituting a year—extra months being occasionally intercalated, so that the seasons might recur at about the same period of the year. In 46 b.c. Julius Caesar decreed that thenceforth the year should contain 365 days, except that in every fourth or leap year one additional day should be introduced. He ordered this rule to come into force on January 1, 45 b.c. The change was made on the advice of Sosigenes of Alexandria. It must be remembered that the year 1 a.d. follows immediately 1 b.c., that is, there is no year 0, and thus 45 b.c. would be a leap year. All historical dates are given now as if the Julian calendar was reckoned backwards as well as forwards from that year* . As a matter of fact, owing to a mistake in the original decree, the Romans, during the * Herschel, Astronomy, London, 11th ed. 1871, arts. 916–919. 292 TIME AND ITS MEASUREMENT. [CH. XIII first 36 years after 45 b.c., intercalated the extra day every third year, thus producing an error of 3 days. This was remedied by Augustus, who directed that no intercalation of an extra day should be made in any of the twelve years a.u.c. 746 to 757 inclusive, but that the intercalation should be again made in the year a.u.c. 761 (that is, 8 a.d.) and every succeeding fourth year. The Julian calendar made the year, on an average, contain 365.25 days. The actual value is, very approximately, 365.242216 days. Hence the Julian year is too long by about 11 1 4 minutes: this produces an error of nearly one day in 128 years. If the extra day in every thirtysecond leap year had been omitted—as was suggested by some unknown Persian astronomer—the error would have been less than one day in 100,000 years. It may be added that Sosigenes was aware that his rule made the year slightly too long. The error in the Julian calendar of rather more than eleven minutes a year gradually accumulated, until in the sixteenth century the seasons arrived some ten days earlier than they should have done. In 1582 Gregory XIII corrected this by omitting ten days from that year, which therefore contained only 355 days. At the same time he decreed that thenceforth every year which was a multiple of a century should be or not be a leap year according as the multiple was or was not divisible by four. The fundamental idea of the reform was due to Lilius, who died before it was carried into effect. The work of framing the new calendar was entrusted to Clavius, who explained the principles and necessary rules in a prolix but accurate work* of over 700 folio pages. The plan adopted was due to a suggestion of Pitatus made in 1552 or perhaps 1537: the alternative and more accurate proposal of Stöffler, made in 1518, to omit one day in every 134 years being rejected by Lilius

and Clavius for reasons which are not known. Clavius believed the year to contain 365.2425432 days, but he framed his calendar so that a year, on the average, contained 365.2425 days, which he thought to be wrong by one day in 3323 years: in reality it is a trifle more accurate than this, the error amounting to one day in about 3600 years. The change was unpopular, but Riccioli† tells us that, as those * Romani Calendarii a Greg. XIII, restituti Explicatio, Rome, 1603. † Chronologia Reformata, Bonn, 1669, vol. ii, p. 206. CH. XIII] TIME AND ITS MEASUREMENT. 293 miracles which take place on fixed dates—ex. gr. the liquefaction of the blood of S. Januarius—occurred according to the new calendar, the papal decree was presumed to have a divine sanction—Deo ipso huic correctioni Gregorianae subscribente—and was accepted as a necessary evil. In England a bill to carry out the same reform was introduced in 1584, but was withdrawn after being read a second time; and the change was not finally effected till 1752, when eleven days were omitted from that year. In Roman Catholic countries the new style was adopted in 1582. In Scotland the change was made in 1600. In the German Lutheran States it was made in 1700. In England, as I have said above, it was introduced in 1752; and in Ireland it was made in 1782. It is well known that the Greek Church still adheres to the Julian calendar. The Mohammedan year contains 12 lunar months, or 354 1 3 days, and thus has no connection with the seasons. The Gregorian change in the calendar was introduced in order to keep Easter at the right time of year. The date of Easter depends on that of the vernal equinox, and as the Julian calendar made the year of an average length of 365.25 days instead of 365.242216 days, the vernal equinox came earlier and earlier in the year, and in 1582 had regreded to within about ten days of February. The rule for determining Easter is as follows* . In 325 the Nicene Council decreed that the Roman practice should be followed; and after 463 (or perhaps, 530) the Roman practice required that Easter-day should be the first Sunday after the full moon which occurs on or next following the vernal equinox—full moon being assumed to occur on the fourteenth day from the day of the preceding new moon (though as a matter of fact it occurs on an average after an interval of rather more than 14 3 4 days), and the vernal equinox being assumed to fall on March 21 (though as a matter of fact it sometimes falls on March 22). This rule and these assumptions were retained by Gregory on the ground that it was inexpedient to alter a rule with which so many traditions were associated; but, in order to save disputes as to the exact instant of the occurrence of the new moon, a mean sun and a mean moon defined by Clavius were used in applying the rule. One consequence of using this mean sun and mean moon and giving an * De Morgan, Companion to the Almanac, London, 1845, pp. 1–36; Ibid., 1846, pp. 1–10. 294 TIME AND ITS MEASUREMENT. [CH. XIII artificial definition of full moon is that it may happen, as it did in 1818 and 1845, that the actual full moon occurs on Easter Sunday. In the British Act, 24 Geo. II. cap. 23, the

explanatory clause which defines full moon is omitted, but practically full moon has been interpreted to mean the Roman ecclesiastical full moon; hence the Anglican and Roman rules are the same. Until 1774 the German Lutheran States employed the actual sun and moon. Had full moon been taken to mean the fifteenth day of the moon, as is the case in the civil calendar, then the rule might be given in the form that Easter-day is the Sunday on or next after the calendar full moon which occurs next after March 21. Assuming that the Gregorian calendar and tradition are used, there still remains one point in this definition of Easter which might lead to different nations keeping the feast at different times. This arises from the fact that local time is introduced. For instance the difference of local time between Rome and London is about 50 minutes. Thus the instant of the first full moon next after the vernal equinox might occur in Rome on a Sunday morning, say at 12.30 a.m., while in England it would still be Saturday evening, 11.40 p.m., in which case our Easter would be one week earlier than at Rome. Clavius foresaw the difficulty, and the Roman Communion all over the world keep Easter on that day of the month which is determined by the use of the rule at Rome. But presumably the British Parliament intended time to be determined by the Greenwich meridian, and if so the Anglican and Roman dates for Easter might differ by a week; whether such a case has ever arisen or been discussed I do not know, and I leave to ecclesiastics to say how it should be settled. The usual method of calculating the date on which Easter-day falls in any particular year is involved, and possibly the following simple rule* may be unknown to some of my readers. Let m and n be numbers as defined below. (i) Divide the number of the year by 4, 7, 19; and let the remainders be a, b, c, respectively. (ii) Divide 19c + m by 30, and let d be the remainder. (iii) Divide 2a + 4b + 6d + n by 7, and let e be the remainder. (iv) Then the Easter full moon occurs d days after March 21; and Easter-day is the (22 + d + e)th of March or the (d + e − 9)th day of April, except that if the calculation gives d = 29 and e = 6 (as happens in 1981) then * It is due to Gauss, and his proof is given in Zach's Monatliche Correspondenz, August, 1800, vol. ii, pp. 221–230. CH. XIII] TIME AND ITS MEASUREMENT. 295 Easter-day is on April 19 and not on April 26, and if the calculation gives d = 28, e = 6, and also c > 10 (as happens in 1954) then Easterday is on April 18 and not on April 25, that is, in these two cases Easter falls one week earlier than the date given by the rule. These two exceptional cases cannot occur in the Julian calendar, and in the Gregorian calendar they occur only very rarely. It remains to state the values of m and n for the particular period. In the Julian calendar we have m = 15, n = 6. In the Gregorian calendar we have, from 1582 to 1699 inclusive, m = 22, n = 2; from 1700 to 1799, m = 23, n = 3; from 1800 to 1899, m = 23, n = 4; from 1900 to 2099, m = 24, n = 5; from 2100 to 2199, m = 24, n = 6; from 2200 to 2299, m = 25, n = 0; from 2300 to 2399, m = 26, n = 1; and from 2400 to 2499, m = 25, n = 1. Thus for the year 1908 we have m = 24, n = 5; hence a = 0, b = 4, c = 8; d = 26; and e = 2: therefore

Easter Sunday will be on the 19th of April. After the year 4200 the form of the rule will have to be slightly modified. The dominical letter and the golden number of the ecclesiastical calendar can be at once determined from the values of b and c. The epact, that is, the moon's age at the beginning of the year, can be also easily calculated from the above data in any particular case; the general formula was given by Delambre, but its value is required so rarely by any but professional astronomers and almanack-makers that it is unnecessary to quote it here. We can evade the necessity of having to recollect the values of m and n by noticing that, if N is the given year, and if {N/x} denotes the integral part of the quotient when N is divided by x, then m is the remainder when 15 + ξ is divided by 30, and n is the remainder when 6 + η is divided by 7: where, in the Julian calendar, ξ = 0, and η = 0; and, in the Gregorian calendar, ξ = {N/100} − {N/400} − {N/300}, and η = {N/100} − {N/400} − 2. If we use these values of m and n, and if we put for a, b, c, their values, namely, a = N −4{N/4}, b = N −7{N/7}, c = N −19{N/19}, the rule given on the preceding page takes the following form. "Divide 19N − {N/19} + 15 + ξ by 30, and let the remainder be d. Next divide 6(N + d + 1) − {N/4} + η by 7, and let the remainder be e. Then Easter full moon is on the dth day after March 21, and Easter-day is on the (22 + d + e)th of March or the (d + e − 9)th of April as the case may be; except that if the calculation gives d = 29, and e = 6, 296 TIME AND ITS MEASUREMENT. [CH. XIII or if it gives d = 28, e = 6, and c > 10, then Easter-day is on the (d + e − 16)th of April." Thus, if N = 1899, we divide 19(1899)−99+15+(18−4−6) by 30, which gives d = 5, and then we proceed to divide 6(1899 + 5 + 1) − 474 +(18−4−2) by 7, which gives e = 6: therefore Easter-day is on April 2. The above rules cover all the cases worked out with so much labour by Clavius and others* . I may add here a rule, quoted by Zeller, for determining the day of the week corresponding to any given date. Suppose that the pth day of the qth month of the year N anno domini is the rth day of the week, reckoned from the preceding Saturday. Then r is the remainder when p + 2q + {3(q + 1)/5} + N + {N/4} − η is divided by 7; provided January and February are reckoned respectively as the 13th and 14th months of the preceding year. For instance, Columbus first landed in the New World on Oct. 12, 1492. Here p = 12, q = 10, N = 1492, η = 0. If we divide 12 + 20 + 6 + 1492 + 373 by 7 we get r = 6; hence it was on a Friday. Again, Charles I was executed on Jan. 30, 1649. Here p = 30, q = 13, N = 1648, η = 0, and we find r = 3; hence it was on a Tuesday. As another example, the battle of Waterloo was fought on June 18, 1815. Here p = 18, q = 6, N = 1815, η = 12, and we find r = 1; hence it took place on a Sunday. I proceed now to give a short account of some of the means of measuring time which were formerly in use. Of devices for measuring time, the earliest of which we have any positive knowledge are the styles or gnomons erected in Egypt and Asia Minor. These were sticks placed vertically in a horizontal piece of ground, and surrounded by three concentric circles, such that every two hours the end of the shadow of

the stick passed from one circle to another. Some of these have been found at Pompeii and Tusculum. The sun-dial is not very different in principle. It consists of a rod or style fixed on a plate or dial; usually, but not necessarily, the style is placed so as to be parallel to the axis of the earth. The shadow of the * Most of the above-mentioned facts about the calendar are taken from Delambre's Astronomie, Paris, 1814, vol. iii, chap. xxxviii; and his Histoire de l'astronomie moderne, Paris, 1821, vol. i, chap. i: see also A. De Morgan, The Book of Almanacs, London, 1851; S. Butcher, The Ecclesiastical Calendar, Dublin, 1877; and C. Zeller, Acta Mathematica, Stockholm, 1887, vol. ix, pp. 131–136: on the chronological details see J.L. Ideler, Lehrbuch der Chronologie, Berlin, 1831. CH. XIII] TIME AND ITS MEASUREMENT. 297 style cast on the plate by the sun falls on lines engraved there which are marked with the corresponding hours. The earliest sun-dial, of which I have read, is that made by Berosus in 540 b.c. One was erected by Meton at Athens in 433 b.c. The first sun-dial at Rome was constructed by Papirius Cursor in 306 b.c. Portable sun-dials, with a compass fixed in the face, have been long common in the East as well as in Europe. Other portable instruments of a similar kind were in use in medieval Europe, notably the sun-rings, hereafter described, and the sun-cylinders* . I believe it is not generally known that a sun-dial can be so constructed that the shadow will, for a short time near sunrise and sunset, move backwards on the dial† . This was discovered by Nonez. The explanation is as follows. Every day the sun appears to describe a circle round the pole, and the line joining the point of the style to the sun describes a right cone whose axis points to the pole. The section of this cone by the dial is the curve described by the extremity of the shadow, and is a conic. In our latitude the sun is above the horizon for only part of the twenty-four hours, and therefore the extremity of the shadow of the style describes only a part of this conic. Let QQ' be the arc described by the extremity of the shadow of the style from sunrise at Q to sunset at Q' , and let S be the point of the style and F the foot of the style, i.e. the point where the style meets the plane of the dial. Suppose that the dial is placed so that the tangents drawn from F to the conic QQ' are real, and that P and P ' , the points of contact of these tangents, lie on the arc QQ' . If these two conditions are fulfilled, then the shadow will regrede through the angle QF P as its extremity moves from Q to P, it will advance through the angle P F P' as its extremity moves from P to P ' , and it will regrede through the angle P 'F Q' as its extremity moves from P ' to Q' . If the sun's apparent diurnal path crosses the horizon—as always happens in temperate and tropical latitudes—and if the plane of the dial is horizontal, the arc QQ' will consist of the whole of one branch of a hyperbola, and the above conditions will be satisfied if F is within the space bounded by this branch of the hyperbola and its asymptotes. * Thus Chaucer in the Shipman's Tale, "by my chilindre it is prime of day," and Lydgate in the Siege of Thebes, "by my chilyndre I gan anon to see. . . that it drew to nine." † Ozanam, 1803

edition, vol. iii, p. 321; 1840 edition, p. 529. 298 TIME AND ITS MEASUREMENT. [CH. XIII As a particular case, in a place of latitude 12◦ N. on a day when the sun is in the northern tropic (of Cancer) the shadow on a dial whose face is horizontal and style vertical will move backwards for about two hours between sunrise and noon. If, in the case of a given sun-dial placed in a certain position, the conditions are not satisfied, it will be possible to satisfy them by tilting the sun-dial through an angle properly chosen. This was the rationalistic explanation, offered by the French encyclopaedists, of the miracle recorded in connection with Isaiah and Hezekiah* . Suppose, for instance, that the style is perpendicular to the face of the dial. Draw the celestial sphere. Suppose that the sun rises at M and culminates at N, and let L be a point between M and N on the sun's diurnal path. Draw a great circle to touch the sun's diurnal path MLN at L, let this great circle cut the celestial meridian in A and A' , and of the arcs AL, A'L suppose that AL is the less and therefore is less than a quadrant. If the style is pointed to A, then, while the sun is approaching L, the shadow will regrede, and after the sun passes L the shadow will advance. Thus if the dial is placed so that a style which is normal to it cuts the meridian midway between the equator and the tropic, then between sunrise and noon on the longest day the shadow will move backwards through an angle sin−1 (cos ω sec 1 2 ω) − cot−1 {sin ω cos(l − 1 2 ω)(cos2 l − sin2 ω) − 1 2 } , where l is the latitude of the place and ω is the obliquity of the ecliptic. The above remarks refer to the sun-dials in ordinary use. In 1892 General Oliver brought out in London a dial with a solid style, the section of the style being a certain curve whose form was determined empirically by the value of the equation of time as compared with the sun's declination† . The shadow of the style on the dial gives the local mean time, though of course in order to set the dial correctly at any place the latitude of the place must be known: the dial may be also set so as to give the mean time at any other locality whose longitude relative to the place of observation is known. The sun-ring or ring-dial is another instrument for measuring solar time‡ . One of the simplest type is figured in the accompanying diagram. * 2 Kings, chap. xx, vv. 9–11. † An account of this sun-dial with a diagram was given in Knowledge, July 1, 1892, pp. 133, 134. ‡ See Ozanam, 1803 edition, vol. iii, p. 317; 1840 edition, p. 526. CH. XIII] TIME AND ITS MEASUREMENT. 299 The sun-ring consists of a thin brass band, about a quarter of an inch wide, bent into the shape of a circle, which slides between two fixed circular rims—the radii of the circles being about one inch. At one point of the band there is a hole; and when the ring is suspended from a fixed point attached to the rims so that it hangs in a vertical plane containing the sun, the light from the sun shines through this hole and makes a bright speck on the opposite inner or concave surface of the ring. On this surface the hours are marked, and, if the ring is properly adjusted, the spot of light will fall on the hour which indicates the solar time. The adjustment for the time of year is made as follows. The rims between which the band

can slide are marked on their outer or convex side with the names of the months, and the band containing the hole must be moved between the rims until the hole is opposite to that month for which the ring is being used. For determining times near noon the instrument is reliable, but for other hours in the day it is accurate only if the time of year is properly chosen, usually near one of the equinoxes. This defect may be corrected by marking the hours on a curved brass band affixed to the concave surface of the rims. I possess two specimens of rings of this kind. These 300 TIME AND ITS MEASUREMENT. [CH. XIII rings were distributed widely. Of my two specimens, one was bought in the Austrian Tyrol and the other in London. Astrolabes and sea-rings can be used as sun-rings. Clepsydras or water-clocks, and hour-glasses or sand-clocks, afford other means of measuring time. The time occupied by a given amount of some liquid or sand in running through a given orifice under the same conditions is always the same, and by noting the level of the liquid which has run through the orifice, or which remains to run through it, a measure of time can be obtained. The burning of graduated candles gives another way of measuring time, and we have accounts of those used by Alfred the Great for the purpose. Incense sticks were used by the Chinese in a similar way. Modern clocks and watches * comprise a train of wheels turned by a weight, spring, or other motive power, and regulated by a pendulum, balance, fly-wheel, or other moving body whose motion is periodic and time of vibration constant. The direction of rotation of the hands of a clock was selected originally so as to make the hands move in the same direction as the shadow on a sun-dial whose face is horizontal—the dial being situated in our hemisphere. The invention of clocks with wheels is attributed by tradition to Pacificus of Verona, circ. 850, and also to Gerbert, who is said to have made one at Magdeburg in 996: but there is reason to believe that these were sun-clocks. The earliest wheel-clock of which we have historical evidence was one sent by the Sultan of Egypt in 1232 to the Emperor Frederick II, though there seems to be no doubt that they had been made in Italy at least fifty years earlier. The oldest clock in England of which we know anything was one erected in 1288 in or near Westminster Hall out of a fine imposed on a corrupt Lord Chief Justice. The bells, and possibly the clock, were staked by Henry VIII on a throw of dice and lost, but the site was marked by a sun-dial, destroyed about sixty years ago, and bearing the inscription Discite justiciam moniti. In 1292 a clock was erected in Canterbury Cathedral at a cost of £30. One erected at Glastonbury Abbey in 1325 is at present in the Kensington Museum and is in regular action. Another made in 1326 for St Alban’s Abbey showed the astronomical phenomena, and seems to have been one of the earliest clocks that did so. One put up at Dover in 1348 is still in good working order. * See Clock and Watch Making by Lord Grimthorpe, 7th edition, London, 1883. CH. XIII] TIME AND ITS MEASUREMENT. 301 The clocks at Peterborough and Exeter were of about the same date, and portions

of them remain in situ. Most of these early clocks were regulated by horizontal balances: pendulums being then unknown. Of the elaborate clocks of a later date, that at Strasburg made by Dasypodius in 1571, and that at Lyons constructed by Lippeus in 1598, are especially famous: the former was restored in 1842, though in a manner which destroyed most of the ancient works. In 1370, Vick constructed a clock for Charles V with a weight as motive power and a vibrating escapement—a great improvement on the rough time-keepers of an earlier date. The earliest clock regulated by a pendulum seems to have been made in 1621 by a clockmaker named Harris, of Covent Garden, London, but the theory of such clocks is due to Huygens* . Galileo had discovered previously the isochronism of a pendulum, but did not apply it to the regulation of the motion of clocks. Hooke made such clocks, and possibly discovered independently this use of the pendulum: he invented or re-invented the anchor pallet. A watch may be defined as a clock which will go in any position. Watches, though of a somewhat clumsy design, were made at Nuremberg by P. Hele early in the sixteenth century—the motive power being a ribbon of steel, wound round a spindle, and connected at one end with a train of wheels which it turned as it unwound—and possibly a few similar time-pieces had been made in the previous century. By the end of the sixteenth century they were not uncommon. At this time they were usually made in the form of fanciful ornaments such as skulls, or as large pendants, but about 1620 the flattened oval form was introduced, rendering them more convenient to carry in a pocket or about the person. In the seventeenth century their construction was greatly improved, notably by the introduction of the spring balance by Huygens in 1674, and independently by Hooke in 1675—both mathematicians having discovered that small vibrations of a coiled spring, of which one end is fixed, are practically isochronous. The fusee had been used by R. Zech of Prague in 1525, but was re-invented by Hooke. Clocks and watches are usually moved and regulated in the manner indicated above. Other motive powers and other devices for regulating the motion may be met with occasionally. Of these I may mention a clock in the form of a cylinder, usually attached to another weight as * Horologium Oscillatorium, Paris, 1673. 302 TIME AND ITS MEASUREMENT. [CH. XIII in Atwood's machine, which rolls down an inclined plane so slowly that it takes twelve hours to roll down, and the highest point of the face always marks the proper hour* . A water-clock made on a somewhat similar plan is described by Ozanam† as one of the sights of Paris at the beginning of the last century. It was formed of a hollow cylinder divided into various compartments each containing some mercury, so arranged that the cylinder descended with uniform velocity between two vertical pillars on which the hours were marked at equidistant intervals. Other ingenious ways of concealing the motive power have been described in the columns of La Nature ‡ . Of such mysterious timepieces the following are not uncommon examples, and probably are known to

most readers of this book. One kind of clock consists of a glass dial suspended by two thin wires; the hands however are of metal, and the works are concealed in them or in the pivot. Another kind is made of two sheets of glass in a frame containing a spring which gives to the hinder sheet a very slight oscillatory motion–imperceptible except on the closest scrutiny–and each oscillation moves the hands through the requisite angles. Some so-called perpetual motion timepieces were described above on pages 77–78. Lastly, I have seen in France a clock the hands of which were concealed at the back of the dial, and carried small magnets; pieces of steel in the shape of insects were placed on the dial, and, following the magnets, served to indicate the time. The position of the sun relative to the points of the compass determines the solar time. Conversely, if we take the time given by a watch as being the solar time—and it will differ from it by only a few minutes at the most—and we observe the position of the sun, we can find the points of the compass§ . To do this it is sufficient to point the hour-hand to the sun, and then the direction which bisects the angle between the hour and the figure xii will point due south. For instance, if it is four o'clock in the afternoon, it is sufficient to point the hourhand (which is then at the figure iiii) to the sun, and the figure ii on the watch will indicate the direction of south. Again, if it is eight * Ozanam, 1803 edition, vol. ii, p. 39; 1840 edition, p. 212; or La Nature, Jan. 23, 1892, pp. 123, 124. † Ozanam, 1803 edition, vol. ii, p. 68; 1840 edition, p. 225. ‡ See especially the volumes issued in 1874, 1877, and 1878. § The rule is given by W.H. Richards, Military Topography, London, 1883, p. 31, though it is not stated quite correctly. I do not know who first enunciated it. CH. XIII] TIME AND ITS MEASUREMENT. 303 o'clock in the morning, we must point the hour-hand (which is then at the figure viii) to the sun, and the figure x on the watch gives the south point of the compass. Between the hours of six in the morning and six in the evening the angle between the hour and xii which must be bisected is less than 180◦ , but at other times the angle to be bisected is greater than 180◦ ; or perhaps it is simpler to say that at other times the rule gives the north point and not the south point. The reason is as follows. At noon the sun is due south, and it makes one complete circuit round the points of the compass in 24 hours. The hour-hand of a watch also makes one complete circuit in 12 hours. Hence, if the watch is held in the plane of the ecliptic with its face upwards, and the figure xii on the dial is pointed to the south, both the hour-hand and the sun will be in that direction at noon. Both move round in the same direction, but the angular velocity of the hour-hand is twice as great as that of the sun. Hence the rule. The greatest error due to the neglect of the equation of time is less than 2 ◦ . Of course in practice most people, instead of holding the face of the watch in the ecliptic, would hold it horizontal, and in our latitude no serious error would be thus introduced. In the southern hemisphere where at noon the sun is due north the rule requires modification. In such places the hour-hand of a watch (held

face upwards in the plane of the ecliptic) and the sun move in opposite directions. Hence, if the watch is held so that the figure xii points to the sun, then the direction which bisects the angle between the hour of the day and the figure xii will point due north. CHAPTER XIV. MATTER AND ETHER THEORIES. Matter, like space and time, cannot be defined, but either the statement that matter is whatever occupies space or the statement that it is anything which can be seen, touched, or weighed, suggests its more important characteristics to anyone already familiar with it. The means of measuring matter and some of its properties are treated in most text-books on mechanics, and I do not propose to discuss them. I confine the chapter to an account of some of the hypotheses by physicists as to the ultimate constitution of matter, but I exclude metaphysical conjectures, which from their nature are mere assertions incapable of proof and are not subject to mathematical analysis. The question is intimately associated with the explanation of the phenomena of attraction, light, chemistry, electricity, and other branches of physics. I commence with a list of some of the more plausible of the hypotheses formerly proposed which accounted for the obvious properties of matter, and shall then discuss how far they explain or are consistent with other facts† . The interest of the list is largely historical, for within the last few years new views as to the constitution of matter † I have based my account mainly on Recent Advances in Physical Science, by P.G. Tait, Edinburgh, 1876 (chaps, xii, xiii); and on the article Atom by J. Clerk Maxwell in the Encyclopaedia Britannica or his Collected Works, vol. ii, pp. 445– 484: see also W.M. Hicks's address, Report of the British Association (Ipswich meeting), 1895, vol. lxv, pp. 595–606. For the more recent speculations see J.J. Thomson, Electricity and Matter, Westminster, 1904, and J. Larmor, Aether and Matter, Cambridge, 1900. 304 CH. XIV] MATTER AND ETHER THEORIES. 305 have been propounded, but the details of these more recent hypotheses are so complicated and technical that only professional mathematicians can understand them. Accordingly I allude to them only briefly. I. Hypothesis of Continuous Matter. It may be supposed that matter is homogeneous and continuous, in which case there is no limit to the infinite divisibility of bodies. This view was held by Descartes* . This conjecture is consistent with the facts deducible by untrained observation, but there are many other phenomena for which it does not account; moreover there seems to be no way of reconciling such a structure of matter either with the facts of chemical changes or with the results of spectrum analysis. At any rate the theory must be regarded as extremely improbable. II. Atomic Theories. If matter is not continuous we must suppose that every body is composed of aggregates of molecules. If so, it seems probable that each such molecule is built up by the association of two or more atoms, that the number of kinds of atoms is finite, and that the atoms of any particular kind are alike. As to the nature of the atoms the following hypotheses have been made. (i) Popular Atomic Hypothesis. The popular view is

that every atom of any particular kind is a minute indivisible article possessing definite qualities, everlasting in its form and properties, and infinitely hard. This statement is plausible, but the difficulties to which it leads appear to be insuperable. In fact we have reason to think that the atoms which form a molecule are composite systems in incessant vibration at a rate characteristic of the molecule, and it is most probable that they are elastic. Newton seems to have hazarded a conjecture of this kind when he suggested† that the difficulties, connected with the fact that the velocity of sound was one-ninth greater than that required by theory, might be overcome if the particles of air were little rigid spheres whose distance from one another under normal conditions was nine times the * Descartes, Principia, vol. ii, pp. 18, 23. † Newton, Principia, bk. ii, prop. 50. 306 MATTER AND ETHER THEORIES. [CH. XIV diameter of any one of them. This was ingenious, but obviously the view is untenable, because, if such a structure of air existed, the air could not be compressed beyond a certain limit, namely, about 1/1021st part of its original volume, which has been often exceeded. The true explanation of the difficulty noticed by Newton was given by Laplace. (ii) Boscovich's Hypothesis. In 1759 Boscovich suggested* that the facts might be explained by supposing that an atom was an infinitely small indivisible mass which was a centre of force—the law of force being attractive for sensible distances, alternately attractive and repulsive for minute distances, and repulsive for infinitely small distances. In this theory all action between bodies is action at a distance. He explained the apparent extension of bodies by saying that two parts are consecutive (or similarly that two bodies are in contact) when the nearest pair of atoms in them are so close to one another that the repulsion at any point between them is sufficiently great to prevent any other atom coming between them. It is essential to the theory that the atom shall have a mass but shall not have dimensions. This hypothesis is not inconsistent with any known facts, but it has been described, perhaps not unjustly, as a mere mathematical fiction, and certainly it is opposed to the apparent indications of our senses. At any rate it is artificial, though it may be a prejudice to regard that as an argument against its adoption. To some extent this view was accepted by Faraday. Lord Kelvin, better known as Sir William Thomson, has shown† that, if we assume the existence of gravitation, then each of the above hypotheses will account for cohesion. (iii) Hypothesis of an Elastic Solid Ether. Some physicists have tried to explain the known phenomena by properties of the medium through which our impressions are derived. By postulating that all space is filled with a medium possessed of many of the characteristics of an elastic solid, it has been shown by Fresnel, Green, Cauchy, Neumann, MacCullagh, and others that a large number of the properties of light and electricity may be explained. In spite of the difficulties to which this hypothesis necessarily leads, and of its inherent improbabil- * Philosophiae naturalis Theoria redacta ad unicam Legem Virium, Vienna, 1759. † Proceedings of the Royal Society of

Edinburgh, April 21, 1862, vol. iv, pp. 604– 606. CH. XIV] MATTER AND ETHER THEORIES. 307 ity, it has been discussed by Stokes, Lamé, Boussinesq, Sarrau, Lorenz, Lord Rayleigh, and Kirchhoff. This hypothesis has been modified and rendered somewhat more plausible by von Helmholtz, Lommel, Ketteler* , and Voigt, who based their researches on the assumption of a mutual reaction between the ether and the material molecules located in it: on this view the problems connected with refraction and dispersion have been simplified. Finally, Sir William Thomson, in his Baltimore Lectures, 1885, suggested a mechanical analogue to represent the relations between matter and this ether, by which a possible constitution of the ether can be realized. He also suggested later a form of labile ether , from whose properties most of the more familiar physical phenomena can be deduced, provided the arrangement can be considered stable; a labile ether is an elastic solid, and its properties in two dimensions may be compared with those of a soap-bubble film, in three dimensions. It is, however, difficult to criticise any of these hypotheses as a theory of the constitution of matter until the arrangement of the atoms or their nature is more definitely expressed. III. Dynamical Theories. In recent years the suggestion has been made that the so-called atoms may be forms of motion (ex. gr. permanent eddies) in one elementary material known as the ether; on this view all the atoms are constituted of the same matter, but the physical conditions are different for the different kinds of atoms. It has been said that there is an initial difficulty in any such hypothesis, since the all-pervading elementary fluid must possess inertia, so that to explain matter we assume the existence of a fluid possessing one of the chief characteristics of matter. This is true as far as it goes, but it is not more unreasonable than to attribute all the fundamental properties of matter to the atoms themselves, as is done by many writers. The next paragraph contains a statement of one of the earliest attempts to formulate a dynamical atomic hypothesis. (i) The Vortex Ring Hypothesis. This hypothesis assumes that each atom is a vortex ring in an incompressible frictionless homogeneous fluid. * Theoretische Optik, Braunschweig, 1885. 308 MATTER AND ETHER THEORIES. [CH. XIV Vortex rings—though, since friction is brought into play, of an imperfect character—can be produced in air by many smokers. Better specimens can be formed by taking a cardboard box in one side of which a circular hole is cut, filling it with smoke, and hitting the opposite side sharply. The tendency of the particles forming a ring to maintain their annular connection may be illustrated by placing such a box on one side of a room in a direct line with the flame of a lighted candle on the other side. If properly aimed, the ring will travel across the room and put out the flame. If the box is filled only with air, so that the ring is not visible, the experiment is more effective. In 1858 von Helmholtz* showed that a closed vortex filament in a perfect fluid is indestructible and retains certain characteristics always unaltered. In 1867 Sir William Thomson propounded† the idea that matter

consists of vortex rings in a fluid which fills space. If the fluid is perfect we could neither create new vortex rings nor destroy those already created, and thus the permanence of the atoms is explained. Moreover the atoms would be flexible, compressible, and in incessant vibration at a definite fundamental rate. This rate is very rapid, and Sir William Thomson gave the number of vibrations per second of a sodium ring as probably being greater than 1014 . By a development of this hypothesis Prof. J.J. Thomson‡ showed, some years ago, that chemical combination may be explained. He supposed that a molecule of a compound is formed by the linking together of vortex filaments representing atoms of different elements: this arrangement may be compared with that of helices on an anchor ring. For stability not more than six filaments may be combined together, and their strengths must be equal. Another way of explaining chemical combination on the vortex atom hypothesis has been suggested by W.M. Hicks. It is known§ that a spherical mass of fluid, whose interior possesses vortex motion, can move through liquid like a rigid sphere, and he has shown that one of these spherical vortices can swallow up another, thus forming a compound element. * Crelle's Journal, 1858, vol. lv, pp. 25–55; translated by Tait in the Philosophical Magazine, June, 1867, supplement, series 4, vol. xxxiii, pp. 485–512. † Proceedings of the Royal Society of Edinburgh, Feb. 18, 1867, vol. vi, pp. 94–105. ‡ A Treatise on the Motion of Vortex Rings, Cambridge, 1883. § See a memoir by M.J.M. Hill in the Philosophical Transactions of the Royal Society, London, 1894, part i, pp. 213–246. CH. XIV] MATTER AND ETHER THEORIES. 309 (ii) The Vortex Sponge Hypothesis. Any vortex atom hypothesis labours under the difficulty of requiring that the density of the fluid ether shall be comparable with that of ordinary matter. In order to obviate this and at the same time to enable it to transmit transversal radiations Sir William Thomson suggested what has been termed, not perhaps very happily, the vortex sponge hypothesis* : this rests on the assumption that laminar motion can be propagated through a turbulently moving inviscid liquid. The mathematical difficulties connected with such motion have prevented an adequate discussion of this hypothesis, and I therefore confine myself to merely mentioning it. These hypotheses, of vortex motion in a fluid, account for the indestructibility of matter and for many of its properties. But in order to explain statical electrical attraction it would seem necessary to suppose that the ether is elastic; in other words, that an electric field must be a field of strain. If so, complete fluidity in the ether would be impossible, and hence the above theories are now regarded as untenable. (iii) The Ether-Squirts Hypothesis. Prof. Karl Pearson† has suggested another dynamical theory in which an atom is conceived as a point at which ether is pouring into our space from space of four dimensions. If an observer lived in two dimensional space filled with ether and confined by two parallel and adjacent surfaces, and if through a hole in one of these surfaces fresh ether were squirted into this space, the

variations of pressure thereby produced might give the impression of a hard impenetrable body. Similarly an ether-squirt from space of four dimensions into our space might give us the impression of matter. It seems necessary on this hypothesis to suppose that there are also ether-sinks, or atoms of negative mass; but as ether-squirts and ether-sinks would repel one another we may suppose that the latter have moved out of the universe known to our senses. By defining the mass of an atom as the mean rate at which ether is squirting into our space at that point, we can deduce the Newtonian law of gravitation, and by assuming certain periodic variations in the rate of squirting we can deduce some of the phenomena of cohesion, of chemical action, and of electromagnetism and light. But of course the * Philosophical Magazine, London, October, 1887, series 5, vol. xxiv, pp. 342–353. † American Journal of Mathematics, 1891, vol. xiii, pp. 309–362. 310 MATTER AND ETHER THEORIES. [CH. XIV hypothesis rests on the assumption of the existence of a world beyond our senses. (iv) The Electron Hypothesis. MacCullagh, in 1837 and 1839, proposed to account for optical phenomena on the assumption of an elastic ether possessing elasticity of the type required to enable it to resist rotation. This suggestion has been recently modified and extended by Dr J. Larmor* , and, as now enunciated, it accounts for many of the electrical and magnetic (as well as the optical) properties of matter. The hypothesis is however very artificial. The assumed ether is a rotationally elastic incompressible fluid. In this fluid Larmor introduces monad electric elements or electrons, which are nuclei of radial rotational strain. He supposes that these electrons constitute the basis of matter. He further supposes that an electrical current consists of a procession of these electrons, and that a magnetic particle is one in which these entities are revolving in minute orbits. Dynamical considerations applied to such a system lead to an explanation of nearly all the more obvious phenomena. By further postulating that the orbital motion of electrons in the atom constitute it a fluid vortex it is possible to apply the hydrodynamical pulsatory theory of Bjerknes or Hicks and obtain an explanation of gravitation. Thus on this view mass is explained as an electrical manifestation. Electricity in its turn is explained by the existence of electrons, that is, of nuclei of strain in the ether, which are supposed to be in incessant and rapid motion. Whilst, to render this possible, properties are attributed to the ether which are apparently inconsistent with our experience of the space it fills. Put thus, the hypothesis seems very artificial. Perhaps the utmost we can say for it is that, from some points of view, it may, so far as analysis goes, be an approximation to the true theory; in any case much work will have to be done before it can be considered established even as a working hypothesis. Most of the above was written in 1891. Since then investigations on radio-activity have opened up new avenues of conjecture which tend to strengthen the electron theory as a working hypothesis. More than thirty years ago Clerk Maxwell had shown that light and electricity were closely

connected phenomena. It was then believed that both were due to waves in the hypothetical ether, but it was supposed that the phe- * Philosophical Transactions of the Royal Society, London, 1894, pp. 719–822; 1895, pp. 695–743. CH. XIV] MATTER AND ETHER THEORIES. 311 nomena of matter on the one side and of light and electricity on the other were sharply distinguished one from the other. The differences, however, between matter and light tend to disappear as investigations proceed. In 1895 Röntgen established the existence of rays which could produce light, which had the same velocity as light, which were not affected by a magnet, and which could traverse wood and certain other opaque substances like glass. A year later Becquerel showed that uranium was constantly emitting rays which, though not affecting the eye as light, were capable of producing an image on a photographic plate. Like Röntgen rays they can go through thin sheets of metal; like heat rays they burn the skin; like electricity they generate ozone from oxygen. Passed into the air they enable it to conduct the electric current. Their speed has been measured and found to be rather more than half that of light and electricity. It was soon found that thorium possessed a similar property, but in 1903 Prof. Curie showed that radium possessed radio-activity to an extent previously unsuspected in any body, and in fact the rays were so powerful as to make the substance directly visible. Further experiments showed that numerous bodies are radio-active, but the effects are so much more marked in radium that it is convenient to use that substance for most experimental purposes. Radium gives off no less than three kinds of rays besides a radioactive emanation. In these discharges there appears to be a gradual change from what had been supposed to be an elementary form of matter to another. This leads to the belief that of the known forms of matter some, perhaps even all, are not absolutely stable. On the other hand, it may be that only radio-active bodies are unstable, and that in their disintegration we are watching the final stage in the evolution of stable and constant forms of matter. It may, however, in any case turn out that some, or perhaps all, of the so-called elements may be capable of resolution into different combinations of electrons or electricity. At an earlier date J.J. Thomson had concluded that the glow, seen when an electric current passes through a high vacuum tube, is due to a rush of minute particles across the tube. He calculated their weight, their velocity, and the charge of electricity transported by or represented by them, and found these to be constant. They were deflected like Becquerel rays. All space seems to contain them, and electricity, if not identical with them, is at least carried by them. This suggested that these minute particles might be electrons. If so, they might thus 312 MATTER AND ETHER THEORIES. [CH. XIV give the ultimate explanation of electricity as well as matter, and the atom of the chemist would be not an irreducible unit of matter, but a system comprising numerous such minute particles. These conclusions are consistent with those subsequently deduced from experiments with radium. In 1904 the hypothesis

was carried one stage further. In that year J.J. Thomson investigated the conditions of stability of certain systems of revolving particles; and on the hypothesis that an atom of matter consists of a number of particles carrying negative charges of electricity revolving in orbits within a sphere of positive electrification he deduced many of the properties of the different chemical atoms corresponding to different possible stable systems of this kind. His scheme led to results agreeing closely with the results of Mendeléeff's periodic hypothesis. An interesting consequence of this view is that Franklin's description of electricity as subtle particles pervading all bodies, may turn out to be substantially correct. It is also remarkable that corpuscles somewhat analogous to those whose existence was suggested in Newton's corpuscular theory of light should be now supposed to exist in cathode and Becquerel rays. (v) The Bubble Hypothesis* . The difficulty of conceiving the motion of matter through a solid elastic medium has been met in another way, namely, by suggesting that what we call matter is a deficiency of the ether, and that this region of deficiency can move through the ether in a manner somewhat analogous to that in which a bubble can move in a liquid. To express this in technical language we may suppose the ether to consist of an arrangement of minute uniform spherical grains piled together so closely that they cannot change their neighbours, although they can move relatively one to another. Places where the number of grains is less or greater than the number necessary to render the piling normal, move through the medium, as a wave moves through water, though the grains do not move with them. Places where the ether is in excess of the normal amount would repel one another and move away out of our ken, but places where it is below the normal amount would attract each other according to the law of gravity, and constitute particles of matter which would be indestructible. It is alleged that the theory accounts for the known phenomena of gravity, electricity, and light, provided the size of its grains is properly chosen. Reynolds has calculated that for this purpose their diameter should be rather more * O. Reynolds, Submechanics of the Universe, Cambridge, 1903. CH. XIV] THE CAUSE OF GRAVITY 313 than 5×10−18 centimetres, and that the pressure in the medium would be about 104 tons per square centimetre. This theory is in itself more plausible than the electron hypothesis, but its consequences have not yet been fully worked out. Returning from these novel hypotheses to the classical theories of matter, we may now proceed a step further. Before a hypothesis on the structure of matter can be ranked as a scientific theory we may reasonably expect it to afford some explanation of three facts. These are (a) the Newtonian law of attraction; (b) the fact that there are only a finite number of ultimate kinds of matter—such as oxygen, iron, etc.—which can be arranged in a series such that the properties of the successive members are connected by a regular law; and (c) the main results of spectrum analysis. In regard to the first point (a), we can say only that none of the

above theories are inconsistent with the known laws of attraction; and as far as the ether-squirts, the electron, and the bubble hypotheses are concerned, they have been elaborated into a form from which the gravitational law of attraction can be deduced. But we may still say that as to the cause of gravity—or indeed of force—we know nothing. Newton, in his Letters to Bentley, while declaring his ignorance of the cause of gravity, refused to admit the possibility of force acting at a finite distance through a vacuum. "You sometimes speak of gravity," said he* , "as essential and inherent to matter: pray do not ascribe that notion to me, for the cause of gravity is what I do not pretend to know." And in another place he wrote† , "'Tis inconceivable, that inanimate brute matter should (without the mediation of something else which is not material) operate upon and affect other matter without mutual contact; as it must if gravitation in the sense of Epicurus, be essential and inherent in it. . . That gravity should be innate, inherent, and essential to matter, so that one body may act upon another at a distance thro' a vacuum, without the mediation of anything else, by and through which their action and force may be conveyed from one to another, is to me so great an absurdity, that I believe no man who has in * Letter dated Jan. 17, 1693. I quote from the original, which is in the Library of Trinity College, Cambridge; it is printed in the Letters to Bentley, London, 1756, p. 20. † Letter dated Feb. 25, 1693; ibid., pp. 25, 26. 314 MATTER AND ETHER THEORIES. [CH. XIV philosophical matters a competent faculty of thinking can ever fall into it. Gravity must be caused by an agent acting constantly according to certain laws, but whether this agent be material or immaterial, I have left to the consideration of my readers." I have already alluded to conjectural explanations of gravity dependent on the ether-squirts, the electron, and the bubble hypotheses. Of other conjectures as to the cause of gravity, three, which do not involve the idea of force acting at a distance, may be here mentioned: (1) The first of these conjectures was propounded by Newton in the Queries at the end of his Opticks, where he suggested as a possible explanation the existence of a stress in the ether surrounding a particle of matter* . This has been elaborated on a statical basis by Maxwell, who showed† that the stress would have to be at least 3000 times greater than that which the strongest steel would support. Sir William Thomson (Lord Kelvin) has suggested‡ a dynamical way of producing the stress by supposing that space is filled with an incompressible fluid, constantly being annihilated by each atom of matter at a rate proportional to its mass, a constant supply being kept up at an infinite distance. It is true that this avoids Maxwell's difficulty, but we have no right to introduce such sinks and sources of fluid unless we have other grounds for believing in their existence. The conclusion is that Newton's conjecture is very improbable unless we adopt the ether-squirts theory: on that hypothesis it is a plausible explanation. I should add that Maclaurin implies§ that though the above explanation was Newton's early opinion, yet his final view was that he could not

devise any tenable hypothesis about the cause of gravitation. (2) In 1782 Le Sage of Geneva suggested‖ that gravity was caused by the bombardment of streams of ultramundane corpuscles. These * Quoted by S.P. Rigaud in his Essay on the Principia, Oxford, 1838, appendix, pp. 68–70. On other guesses by Newton see Rigaud, text, pp. 61–62, and references there given. † Article Attraction, in Encyclopaedia Britannica, or Collected Works, vol. ii, p. 489. ‡ Proceedings of the Royal Society of Edinburgh, Feb. 7, 1870, vol. vii, pp. 60–63. § An Account of Sir Isaac Newton's Philosophical Discoveries, London, 1748, p. 111. ‖ Mémoires de l'Académie des Sciences for 1782, Berlin, 1784, pp. 404–432: see also the first two books of his Traité de Physique, Geneva, 1818. CH. XIV] THE CAUSE OF GRAVITY 315 corpuscles are supposed to come in all directions from space and to be so small that inter-collisions are rare. A body by itself in space would receive on an average as many blows on one side as on another, and therefore would have no tendency to move. But, if there are two bodies, each will screen the other from some of the bombarding corpuscles. Thus each body will receive more blows on the side remote from the other body than on the side turned towards it. Hence the two bodies will be impelled each towards the other. In order to make this force between two particles vary directly as the product of their masses and inversely as the square of the distance between them, Le Sage showed that it was sufficient to suppose that the mass of a body was proportional to the area of a section at right angles to the direction in which it was attracted. This requires that the constitution of a body shall be molecular, and that the distances between consecutive molecules shall be very large compared with the sizes of the molecules. On the vortex hypothesis we may suppose that the ultramundane corpuscles are vortex rings. This is ingenious, and it is possible that if the corpuscles were perfectly elastic the theory might be tenable* . But the results of Maxwell's numerical calculation show, first, that the particles must be imperfectly elastic; second, that merely to produce the effect of the attraction of the earth on a mass of one pound would require that Le Sage's corpuscles should expend energy at the rate of at least billions† of foot-pounds per second; and third, that it is probable that the effect of such a bombardment would be to raise the temperature of all bodies beyond a point consistent with our experience. Finally, it seems probable that the distance between consecutive molecules would have to be considerably greater than is compatible with the results given below. Tait summed up the objections to these two hypotheses by saying‡ , "One common defect of these attempts is. . . that they all demand some prime mover, working beyond the limits of the visible universe or inside each atom: creating or annihilating matter, giving additional speed to spent corpuscles, or in some other way supplying the exhaustion suffered in the production of gravitation. Another defect is that * See a paper by Sir William Thomson (Lord Kelvin) in the Proceedings of the Royal Society of Edinburgh, Dec. 18, 1871, vol. vii, pp. 577–589. † I use billion with the English

(and not the French) meaning, that is, a billion = 1012 . ‡ Properties of Matter, London, 1885, art. 164. 316 MATTER AND ETHER THEORIES. [CH. XIV they all make gravitation a mere difference-effect, as it were; thereby implying the presence of stores of energy absolutely gigantic in comparison with anything hitherto observed, or even suspected to exist, in the universe; and therefore demanding the most delicate adjustments, not merely to maintain the conservation of energy which we observe, but to prevent the whole solar and stellar systems from being instantaneously scattered in fragments through space. In fact, the cause of gravitation remains undiscovered." (3) There is another conjecture on the cause of gravity which I may mention* . It is possible that the attraction of one particle on another might be explained if both of them rested on a homogeneous elastic body capable of transmitting energy. This is the case if our three-dimensional universe rests in the direction of a fourth dimension on a four-dimensional homogeneous elastic body (which we may call the ether) whose thickness in the fourth dimension is small and constant. The results of spectrum analysis lead us to suppose that every molecule of matter in our universe is in constant vibration. On the above hypothesis these vibrations would cause a disturbance in the supporting space, i.e. in the ether. This disturbance would spread out uniformly in all directions; the intensity diminishing as the square of the distance from the centre of vibration, but the rate of vibration remaining unaltered. The transmission of light and radiant heat may be explained by such vibrations transversal to the direction of propagation. It is possible that gravity may be caused by vibrations in the supporting space which are wholly longitudinal or are compounded of vibrations which are partly longitudinal and partly transversal in any of the three directions at right angles to the direction of propagation. If we define the mass of a molecule as proportional to the intensity of these vibrations caused by it, then at any other point in space the intensity of the vibration there would vary as the mass of the molecule and inversely as the square of the distance from the molecule; hence, if we may assume that such vibrations of the medium spreading out from any centre would draw to that centre a particle of unit mass at any other point with a force proportional to the intensity of the vibration there, then the Newtonian law of attraction would follow. This conjecture is consistent either with Boscovich's hypothesis or with the * See an article by myself in the Messenger of Mathematics, Cambridge, 1891, vol. xxi, pp. 20–24. CH. XIV] FINITE NUMBER OF KINDS OF MATTER 317 vortex theory. It would be interesting if the results of a branch of pure mathematics so abstract as the theory of hyperspace should be found to be closely connected with one of the most fundamental problems of material science. I should sum up the effect of this discussion on gravity on the relative probabilities of the hypotheses as to the constitution of matter enumerated above, by saying that it does not enable us to discriminate between them. The fact that the number of kinds of matter (chemical

elements) is finite and the consequences of spectrum analysis are closely related and may be treated together. The results of spectrum analysis show that every molecule of any species of matter, such as hydrogen, vibrates with (so far as we can tell) exactly equal sets of periods of vibration. This then is one of the characteristics of the particular kind of matter, and it is probable that any explanation of why the molecules of each kind have a definite set of periods of vibration will account also for the fact that the number of kinds of matter is finite. Various attempts to explain why the molecules of matter are capable only of certain definite periods of vibration have been made, and it may be interesting if I give them briefly. (1) To begin with, I may note the conjecture that it depends on properties of time. This, however, is impossible, for the continuity of certain spectra proves that in these cases there is nothing which prevents the period of vibration from taking any one of millions of different values: thus no explanation dependent on the nature of time is permissible. (2) It has been suggested that there may have been a sorting agency, and only selected specimens of the infinite number of species formed originally have got into our universe. The objection to this is that no explanation is offered as to what has become of the excluded molecules. (3) The finite number of species might be explained by supposing a physical connection to exist between all the molecules in the universe, just as two clocks whose rates are nearly the same tend to go at the same rate if their cases are connected. Maxwell's objection to this is that we have no other reason for supposing that such a connection exists, but if we are living in a space of 318 MATTER AND ETHER THEORIES. [CH. XIV four dimensions as suggested above in chapter xii, this connection does exist, for all the molecules rest on one and the same body. This body is capable of transmitting vibrations, hence, no matter how the molecules were set vibrating originally, they would fall into certain groups, and all the members of each group would vibrate at the same rate. It was the possibility of obtaining thus a physical connection between the various particles in our universe that first suggested to me the idea of a supporting medium in a fourth dimension. (4) If we accept Boscovich's hypothesis or that of an elastic solid ether, and if we may lay it down as axiomatic that the mass of every sub-atom is the same, we may conceive that the number of ways of combining the sub-atoms into a permanent system is limited, and that the period of vibration depends on the form in which the sub-atoms are combined into an atom. This view is not inconsistent with any known facts. I may add that it is probable that the chemical atom is the essential vibrating system, for the sodium spectrum, to take one instance, is the same as that of all its compounds. (5) In the same way we may suppose that the vortex rings are formed so that they can have only a definite number of stable forms produced by interlinking or kinking. (6) Similarly we may modify the popular hypothesis by treating the atoms as indivisible aggregates of sub-atoms which are in all respects equal and similar, and can be

combined in only a limited number of forms which are permanent. But most of the old difficulties connected with the atoms arise again in connection with the sub-atoms. (7) I am not aware that Maxwell discussed any other hypotheses in connection with this point, but it has been suggested recently that, if the various forms of matter were evolved originally out of some one primitive material, then there may have been periodic disturbances in this matter when the atoms were being formed, such that they were produced only at some definite phase in the period* . Thus, if the disturbance is represented by the swinging of a pendulum in a resisting medium, it might be supposed that the atoms were formed at the points of maximum amplitude, and we should expect that the atoms successively thrown off would form a series having the properties of its successive members connected by a regular periodic law. * See Crookes on Mendeléeff's periodic law, Nature, Sept. 2, 1886, vol. xxxiv, pp. 423–432. CH. XIV] THE SIZE OF MOLECULES OF MATTER. 319 This conjecture, when worked out in some detail, led to the conclusion that some elements which ought to have appeared in the series were missing, but it was possible to predict their properties and to suggest the substances with which they were most likely to be found in combination. Guided by these theoretical conclusions a careful chemical analysis revealed the fact that such elements did exist. That this hypothesis has led to new discoveries is something in its favour, but I do not wish to be understood to say that it is a theory which leads to results that have been verified subsequently. I should say rather that we have obtained an analogy which is sufficiently like the truth to suggest new discoveries. Such analogies are often the precursors of laws, so that it is not unreasonable to hope that ere long our knowledge of this border-land of chemistry and physics may be more definite, and thus that molecular physics may be brought within the domain of mathematics. It is however very remarkable that J.J. Thomson's conclusions on the stability of the orbital systems he devised should agree so closely with Mendeléeff's periodic law. On the whole Maxwell thought that the phenomena point to a common origin of all molecules of the same kind, that this was an event not belonging to that order of nature under which we live, but must have originated when or before the existing order was established, and that so long as the present order exists it is immutable. This is equivalent to saying that we have arrived at a point beyond which our limited experience does not enable us to carry the explanation. That we should be able to form an approximate idea of the size of the molecules of matter is a testimony to the extraordinary advance which mathematical physics has made recently. Sir William Thomson, now Lord Kelvin, whose ingenuity seems to know no limits—has suggested* four distinct methods of attacking the problem. They lead to results which are not very different. The first of these rests on an assertion of Cauchy that the phenomena of prismatic colours show that the distance between consecutive molecules of matter is comparable with the wave-lengths

of light. Taking the most unfavourable case this would seem to indicate that in a * See Nature, March 31, 1870, vol. i, pp. 531–553; and Tait's Recent Advances, pp. 303–318. The fourth method had been proposed by Loschmidt in 1863. 320 MATTER AND ETHER THEORIES. [CH. XIV transparent homogeneous solid or liquid medium there are not more than 64 × 1024 molecules in a cubic inch, that is, that the distance between consecutive molecules is greater than 1/(4×108)th of an inch. The second method is founded on the amount of work required to draw out a film of liquid, such as a soap-bubble, to a given thickness. This can be calculated from experiments in a capillary tube, and it is found that, if a soap-bubble could be drawn out to a thickness of 1/108 th of an inch there would be but a few molecules in its thickness. This method is not quantitative. Thirdly, Sir William Thomson proved that the contact phenomena of electricity require that in an alloy of brass the distance between two molecules, one of zinc and one of copper, shall be greater than 1/(7×108)th of an inch; hence the number of molecules in a cubic inch of zinc or copper is not greater than 35 × 1025 . Lastly, the kinetic theory of gases leads to the conclusion that certain phenomena of temperature and viscosity depend, inter alia, on inter-molecular collisions, and so on the sizes and velocities of the molecules, while the average velocity with which the molecules move increases with the temperature. This leads to the conclusion that the distance between two consecutive molecules of a gas at normal pressure and temperature is greater than 1/(6 × 106)th of an inch, and is less than 1/107 th of an inch; while the actual size of the molecule is a trifle greater than 1/(3 × 1020)th of a cubic inch; and the number of molecules in a cubic inch is about 3 × 1020 . Thus it would seem that a cubic inch of gas at ordinary pressure and temperature contains about 3 × 1020 molecules, all similar and equal, and each molecule has a volume of about 1/(3×1025)th of a cubic inch; while a cubic inch of the simplest solid or liquid contains rather less than 1027 molecules, and perhaps each molecule has a volume of about 1/(3 × 1026)th of a cubic inch. For instance, if a pea or a drop of water whose radius is 1/16th inch was magnified to the size of the earth, then there would be about thirty molecules in every cubic foot of it, and probably the size of a molecule would be about the same as that of a fives-ball. The average size of the minute drops of water in a very light cloud can be calculated from the coloured rings produced when the sun or moon shines through it. The radius of a drop is about 1/30000th of an inch. Such a drop therefore would contain about 2 × 1013 separate molecules. In gases and vapours, the number of atoms required to make CH. XIV] THE SIZE OF MOLECULES OF MATTER. 321 up one of these molecules can be estimated, but in liquids the number is not as yet known. Loschmidt asserted that a cube whose side is 1/4000th of a millimetre is the smallest object which can be made visible at the present time. Such a cube of oxygen or nitrogen would contain from 60 to 100 millions of molecules of the gas. Also on an average about 50 elementary molecules of

the so-called elements are required to constitute one molecule of organic matter. At least half of every living organism consists of water, and we may for the moment suppose that the remainder consists of organic matter. Hence the smallest living being which is visible under the microscope contains from 30 to 50 millions of elementary molecules which are combined in the form of water, and from 30 to 50 millions of elementary molecules which are combined so as to make not more than one million organic molecules. Hence a very simple organism might be built up out of as few as a million similar organic molecules. Maxwell did not consider that this was sufficient to justify the current conclusions of physiologists, and said that they must not suppose that structural details of infinitely small dimensions can furnish by themselves an explanation of the variety known to exist in the properties and functions of the most minute organisms; but physiologists have replied that whether their conjectures be right or wrong Maxwell's argument is vitiated by his non-consideration of differences due to the physical (as opposed to the chemical) structure of the organism and the consequent motions of the component parts. ROUSE BALL. [Third Edition. Pp. xxiv + 527. Price 10s. net.] MACMILLAN AND CO. Ltd., LONDON AND NEW YORK. This book gives an account of the lives and discoveries of those mathematicians to whom the development of the subject is mainly due. The use of technicalities has been avoided and the work is intelligible to any one acquainted with the elements of mathematics. The author commences with an account of the origin and progress of Greek mathematics, from which the Alexandrian, the Indian, and the Arab schools may be said to have arisen. Next the mathematics of medieval Europe and the renaissance are described. The latter part of the book is devoted to the history of modern mathematics (beginning with the invention of analytical geometry and the infinitesimal calculus), the account of which is brought down to the present time. This excellent summary of the history of mathematics supplies a want which has long been felt in this country. The extremely difficult question, how far such a work should be technical, has been solved with great tact. . . . The work contains many valuable hints, and is thoroughly readable. The biographies, which include those of most of the men who played important parts in the development of culture, are full and general enough to interest the ordinary reader as well as the specialist. Its value to the latter is much increased by the numerous references to authorities, a good table of contents, and a full and accurate index.—The Saturday Review. Mr. Ball's book should meet with a hearty welcome, for though we possess other histories of special branches of mathematics, this is the first serious attempt that has been made in the English language to give a systematic account of the origin and development of the science as a whole. It is written too in an attractive 335 style. Technicalities are not too numerous or obtrusive, and the work is interspersed with biographical sketches and anecdotes likely to interest the general reader. Thus the tyro and the advanced mathematician alike may read it with pleasure and profit.—The Athenæum. A wealth of authorities, often far from accordant with each other, renders a work such as this extremely formidable; and students of mathematics have reason to be grateful for the vast amount of information which has been condensed into this short account. . . . In a survey of so wide extent it is

of course impossible to give anything but a bare sketch of the various lines of research, and this circumstance tends to render a narrative scrappy. It says much for Mr. Ball's descriptive skill that his history reads more like a continuous story than a series of merely consecutive summaries.—The Academy. We can heartily recommend to our mathematical readers, and to others also, Mr. Ball's History of Mathematics. The history of what might be supposed a dry subject is told in the pleasantest and most readable style, and at the same time there is evidence of the most careful research.—The Observatory. All the salient points of mathematical history are given, and many of the results of recent antiquarian research; but it must not be imagined that the book is at all dry. On the contrary the biographical sketches frequently contain amusing anecdotes, and many of the theorems mentioned are very clearly explained so as to bring them within the grasp of those who are only acquainted with elementary mathematics.—Nature. Le style de M. Ball est clair et élégant, de nombreux aperçus rendent facile de suivre le fil de son exposition et de fréquentes citations permettent à celui qui le désire d'approfondir les recherches que l'auteur n'a pu qu'effleurer. . . . Cet ouvrage pourra devenir très utile comme manuel d'histoire des mathématiques pour les étudiants, et il ne sera pas déplacé dans les bibliotheques des savants.—Bibliotheca Mathematica. The author modestly describes his work as a compilation, but it is thoroughly well digested, a due proportion is observed between the various parts, and when occasion demands he does not hesitate to give an independent judgment on a disputed point. His verdicts in such instances appear to us to be generally sound and reasonable. . . . To many readers who have not the courage or the opportunity to tackle the ponderous volumes of Montucla or the (mostly) ponderous treatises of German writers on special periods, it may be somewhat of a surprise to find what a wealth of human interest attaches to the history of so "dry" a subject as mathematics. We are brought into contact with many remarkable men, some of whom have played a great part in other fields, as the names of Gerbert, Wren, Leibnitz, Descartes, Pascal, D'Alembert, Carnot, among others may testify, and with at least one thorough blackguard (Cardan); and Mr. Ball's pages abound with quaint and amusing touches characteristic of the authors under consideration, or of the times in which they lived.—Manchester Guardian. There can be no doubt that the author has done his work in a very excellent way. . . . There is no one interested in almost any part of mathematical science who 336 will not welcome such an exposition as the present, at once popularly written and exact, embracing the entire subject. . . . Mr. Ball's work is destined to become a standard one on the subject.—The Glasgow Herald. A most interesting book, not only for those who are mathematicians, but for the much larger circle of those who care to trace the course of general scientific progress. It is written in such a way that those who have only an elementary acquaintance with the subject can find on almost every page

something of general interest.—The Oxford Magazine. 337 A PRIMER OF THE HISTORY OF MATHEMATICS By W.W. ROUSE BALL. [Second Edition. Pp. iv + 148. Price 2s. net.] MACMILLAN AND CO. Ltd., LONDON AND NEW YORK. This book contains a sketch in popular language of the history of mathematics; it includes some notice of the lives and surroundings of those to whom the development of the subject is mainly due as well as of their discoveries. This Primer is written in the agreeable style with which the author has made us acquainted in his previous essays; and we are sure that all readers of it will be ready to say that Mr. Ball has succeeded in the hope he has formed, that "it may not be uninteresting" even to those who are unacquainted with the leading facts. It is just the book to give an intelligent young student, and should allure him on to the perusal of Mr. Ball's "Short Account." The present work is not a mere réchauffé of that, though naturally most of what is here given will be found in equivalent form in the larger work. . . . The choice of material appears to us to be such as should lend interest to the study of mathematics and increase its educational value, which has been the author's aim. The book goes well into the pocket, and is excellently printed.—The Academy. We have here a new instance of Mr. Rouse Ball's skill in giving in a small space an intelligible account of a large subject. In 137 pages we have a sketch of the progress of mathematics from the earliest records up to the middle of this century, and yet it is interesting to read and by no means a mere catalogue.—The Manchester Guardian. It is not often that a reviewer of mathematical works can confess that he has read one of them through from cover to cover without abatement of interest or fatigue. But that is true of Mr. Rouse Ball's wonderfully entertaining little "History of Mathematics," which we heartily recommend to even the quite rudimentary mathematician. The capable mathematical master will not fail to find a dozen interesting facts therein to season his teaching.—The Saturday Review. 338 A fascinating little volume, which should be in the hands of all who do not possess the more elaborate History of Mathematics by the same author.—The Mathematical Gazette. This excellent sketch should be in the hands of every student, whether he is studying mathematics or no. In most cases there is an unfortunate lack of knowledge upon this subject, and we welcome anything that will help to supply the deficiency. The primer is written in a concise, lucid and easy manner, and gives the reader a general idea of the progress of mathematics that is both interesting and instructive.—The Cambridge Review. Mr. Ball has not been deterred by the existence and success of his larger "History of Mathematics" from publishing a simple compendium in about a quarter of the space. . . . Of course, what he now gives is a bare outline of the subject, but it is ample for all except the most advanced proficients. There is no question that, as the author says, a knowledge of the history of a science lends interest to its study, and often increases its educational value. We can imagine no better cathartic for any mathematical student who has made

some way with the calculus than a careful perusal of this little book.—The Educational Times. The author has done good service to mathematicians by engaging in work in this special field. . . . The Primer gives, in a brief compass, the history of the advance of this branch of science when under Greek influence, during the Middle Ages, and at the Renaissance, and then goes on to deal with the introduction of modern analysis and its recent developments. It refers to the life and work of the leaders of mathematical thought, adds a new and enlarged value to well-known problems by treating of their inception and history, and lights up with a warm and personal interest a science which some of its detractors have dared to call dull and cold.—The Educational Review. It is not too much to say that this little work should be in the possession of every mathematical teacher. . . . The Primer gives in a small compass the leading events in the development of mathematics. . . . At the same time, it is no dry chronicle of facts and theorems. The biographical sketches of the great workers, if short, are pithy, and often amusing. Well-known propositions will attain a new interest for the pupil as he traces their history long before the time of Euclid.—The Journal of Education. This is a work which all who apprehend the value of “mathematics” should read and study. . . , and those who wish to learn how to think will find advantage in reading it.—The English Mechanic. The subject, so far as our own language is concerned, is almost Mr. Ball’s own, and those who have no leisure to read his former work will find in this Primer a highly-readable and instructive chapter in the history of education. The condensation has been skilfully done, the reader’s interest being sustained by the introduction of a good deal of far from tedious detail.—The Glasgow Herald. Mr. W.W. Rouse Ball is well known as the author of a very clever history of mathematics, besides useful works on kindred subjects. His latest production is A Primer of the History of Mathematics, a book of one hundred and forty pages, giving in non-technical language a full, concise, and readable narrative of the development 339 of the science from the days of the Ionian Greeks until the present time. Anyone with a leaning towards algebraic or geometrical studies will be intensely interested in this account of progress from primitive usages, step by step, to our present elaborate systems. The lives of the men who by their research and discovery helped along the good work are described briefly, but graphically. . . . The Primer should become a standard text-book.—The Literary World. This is a capital little sketch of a subject on which Mr. Ball is an acknowledged authority, and of which too little is generally known. Mr. Ball, moreover, writes easily and well, and has the art of saying what he has to say in an interesting style.—The School Guardian. 340 MATHEMATICAL RECREATIONS AND ESSAYS By W.W. ROUSE BALL. [Fourth Edition. Pp. xvi + 402. Price 7s. net.] MACMILLAN AND CO. Ltd., LONDON AND NEW YORK. This work is divided into two parts; the first is on mathematical recreations and puzzles, the second includes some miscellaneous essays and an account of some

problems of historical interest. In both parts questions which involve advanced mathematics are excluded. The mathematical recreations include numerous elementary questions and paradoxes, as well as problems such as the proposition that to colour a map not more than four colours are necessary, the explanation of the effect of a cut on a tennis ball, the fifteen puzzle, the eight queens problem, the fifteen school-girls, the construction of magic squares, the theory and history of mazes, and the knight's path on a chess-board. The second part commences with sketches of the history of the Mathematical Tripos at Cambridge, of the three famous classical problems in geometry (namely, the duplication of the cube, the trisection of an angle, and the quadrature of the circle) and of Mersenne's Numbers. These are followed by essays on Astrology and Ciphers. The last three chapters are devoted to an account of the hypotheses as to the nature of Space and Mass, and the means of measuring Time. Mr. Ball has already attained a position in the front rank of writers on subjects connected with the history of mathematics, and this brochure will add another to his successes in this field. In it he has collected a mass of information bearing upon matters of more general interest, written in a style which is eminently readable, and at the same time exact. He has done his work so thoroughly that he has left few ears for other gleaners. The nature of the work is completely indicated to the mathematical student by its title. Does he want to revive his acquaintance with the Problèmes Plaisans et Délectables of Bachet, or the Récréations Mathématiques et Physiques of Ozanam? Let him take Mr. Ball for his companion, and he will have 341 the cream of these works put before him with a wealth of illustration quite delightful. Or, coming to more recent times, he will have full and accurate discussion of 'the fifteen puzzle,' 'Chinese rings,' 'the fifteen school-girls problem' et id genus omne. Sufficient space is devoted to accounts of magic squares and unicursal problems (such as mazes, the knight's path, and geometrical trees). These, and many other problems of equal interest, come under the head of 'Recreations.' The problems and speculations include an account of the Three Classical Problems; there is also a brief sketch of Astrology; and interesting outlines of the present state of our knowledge of hyper-space and of the constitution of matter. This enumeration badly indicates the matter handled, but it sufficiently states what the reader may expect to find. Moreover for the use of readers who may wish to pursue the several heads further, Mr. Ball gives detailed references to the sources from whence he has derived his information. These Mathematical Recreations we can commend as suited for mathematicians and equally for others who wish to while away an occasional hour.—The Academy. The idea of writing some such account as that before us must have been present to Mr. Ball's mind when he was collecting the material which he has so skilfully worked up into his History of Mathematics. We think this because . . . many bits of ore which would not suit the earlier work find a fitting niche in this. Howsoever the case may be, we are sure that

non-mathematical, as well as mathematical, readers will derive amusement, and, we venture to think, profit withal, from a perusal of it. The author has gone very exhaustively over the ground, and has left us little opportunity of adding to or correcting what he has thus reproduced from his notebooks. The work before us is divided into two parts: mathematical recreations and mathematical problems and speculations. All these matters are treated lucidly, and with sufficient detail for the ordinary reader, and for others there is ample store of references. . . . Our analysis shows how great an extent of ground is covered, and the account is fully pervaded by the attractive charm Mr. Ball knows so well how to infuse into what many persons would look upon as a dry subject.—Nature. A fit sequel to its author's valuable and interesting works on the history of mathematics. There is a fascination about this volume which results from a happy combination of puzzle and paradox. There is both milk for babes and strong meat for grown men. . . . A great deal of the information is hardly accessible in any English books; and Mr. Ball would deserve the gratitude of mathematicians for having merely collected the facts. But he has presented them with such lucidity and vivacity of style that there is not a dull page in the book; and he has added minute and full bibliographical references which greatly enhance the value of his work.—The Cambridge Review. Mathematicians with a turn for the paradoxes and puzzles connected with number, space, and time, in which their science abounds, will delight in Mathematical Recreations and Problems of Past and Present Times.—The Times. Mathematicians have their recreations; and Mr. Ball sets forth the humours of mathematics in a book of deepest interest to the clerical reader, and of no little attractiveness to the layman. The notes attest an enormous amount of research.— The National Observer. 342 Mr. Ball, to whom we are already indebted for two excellent Histories of Mathematics, has just produced a book which will be thoroughly appreciated by those who enjoy the setting of the wits to work. . . . He has collected a vast amount of information about mathematical quips, tricks, cranks, and puzzles—old and new; and it will be strange if even the most learned do not find something fresh in the assortment.—The Observatory. Mr. Rouse Ball has the true gift of story-telling, and he writes so pleasantly that though we enjoy the fulness of his knowledge we are tempted to forget the considerable amount of labour involved in the preparation of his book. He gives us the history and the mathematics of many problems . . . and where the limits of his work prevent him from dealing fully with the points raised, like a true worker he gives us ample references to original memoirs. . . . The book is warmly to be recommended, and should find a place on the shelves of every one interested in mathematics and on those of every public library.—The Manchester Guardian. A work which will interest all who delight in mathematics and mental exercises generally. The student will often take it up, as it contains many problems which puzzle even clever people.—The English Mechanic and World of

Science. This is a book which the general reader should find as interesting as the mathematician. At all events, an intelligent enjoyment of its contents presupposes no more knowledge of mathematics than is now-a-days possessed by almost everybody.—The Athenæum. An exceedingly interesting work which, while appealing more directly to those who are somewhat mathematically inclined, it is at the same time calculated to interest the general reader. . . . Mr. Ball writes in a highly interesting manner on a fascinating subject, the result being a work which is in every respect excellent.— The Mechanical World. É um livro muito interessante, consagrado a recreios mathematicos, alguns dos quaes são muito bellos, e a problemas interessantes da mesma sciencia, que não exige para ser lido grandes conhecimentos mathematicos e que tem em gráo elevado a qualidade de instruir, deleitando ao mesmo tempo.—Journal de sciencias mathematicas, Coimbra. The work is a very judicious and suggestive compilation, not meant mainly for mathematicians, yet made doubly valuable to them by copious references. The style in the main is so compact and clear that what is central in a long argument or process is admirably presented in a few words. One great merit of this, or any other really good book on such a subject, is its suggestiveness; and in running through its pages, one is pretty sure to think of additional problems on the same general lines.—Bulletin of the New York Mathematical Society. A book which deserves to be widely known by those who are fond of solving puzzles . . . and will be found to contain an admirable classified collection of ingenious questions capable of mathematical analysis. As the author is himself a skilful mathematician, and is careful to add an analysis of most of the propositions, it may easily be believed that there is food for study as well as amusement in his pages. . . . Is in every way worthy of praise.—The School Guardian. 343 Once more the author of a Short History of Mathematics and a History of the Study of Mathematics at Cambridge gives evidence of the width of his reading and of his skill in compilation. From the elementary arithmetical puzzles which were known in the sixteenth and seventeenth centuries to those modern ones the mathematical discussion of which has taxed the energies of the ablest investigator, very few questions have been left unrepresented. The sources of the author’s information are indicated with great fulness. . . . The book is a welcome addition to English mathematical literature.—The Oxford Magazine. 344 A HISTORY OF THE STUDY OF MATHEMATICS AT CAMBRIDGE By W.W. ROUSE BALL. [Pp. xvi + 264. Price 6s.] THE UNIVERSITY PRESS, CAMBRIDGE. This work contains an account of the development of the study of mathematics in the university of Cambridge from the twelfth century to the middle of the nineteenth century, and a description of the means by which proficiency in that study was tested at various times. The first part of the book is devoted to a brief account of the more eminent of the Cambridge mathematicians, the subject matter of their works, and their methods of exposition. The second part treats of the manner in which

mathematics was taught, and of the exercises and examinations required of students in past times. A sketch is given of the origin and history of the Mathematical Tripos; this includes the substance of the earlier parts of the author's work on that subject, Cambridge, 1880. To explain the relation of mathematics to other departments of study an outline of the general history of the university and the organization of education therein is added. The present volume is very pleasant reading, and though much of it necessarily appeals only to mathematicians, there are parts—e.g. the chapters on Newton, on the growth of the tripos, and on the history of the university—which are full of interest for a general reader. . . . The book is well written, the style is crisp and clear, and there is a humorous appreciation of some of the curious old regulations which have been superseded by time and change of custom. Though it seems light, it must represent an extensive study and investigation on the part of the author, the essential results of which are skilfully given. We can most thoroughly commend Mr. Ball's volume to all readers who are interested in mathematics or in the growth and the position of the Cambridge school of mathematicians.—The Manchester Guardian. Voici un livre dont la lecture inspire tout d'abord le regret que des travaux analogues n'aient pas été faits pour toutes les Écoles célèbres, et avec autant de soin 345 et de clarté. . . . Toutes les parties du livre nous out vivement intéressé.—Bulletin des sciences mathématiques. A book of pleasant and useful reading for both historians and mathematicians. Mr. Ball's previous researches into this kind of history have already established his reputation, and the book is worthy of the reputation of its author. It is more than a detailed account of the rise and progress of mathematics, for it involves a very exact history of the University of Cambridge from its foundation.—The Educational Times. Mr. Ball is far from confining his narrative to the particular science of which he is himself an acknowledged master, and his account of the study of mathematics becomes a series of biographical portraits of eminent professors and a record not only of the intellectual life of the élite but of the manners, habits, and discussions of the great body of Cambridge men from the sixteenth century to our own. . . . He has shown how the University has justified its liberal reputation, and how amply prepared it was for the larger freedom which it now enjoys.—The Daily News. Mr. Ball has not only given us a detailed account of the rise and progress of the science with which the name of Cambridge is generally associated but has also written a brief but reliable and interesting history of the university itself from its foundation down to recent times. . . . The book is pleasant reading alike for the mathematician and the student of history.—St. James's Gazette. A very handy and valuable book containing, as it does, a vast deal of interesting information which could not without inconceivable trouble be found elsewhere. . . . It is very far from forming merely a mathematical biographical dictionary, the growth of mathematical science being skilfully traced in connection with the successive

names. There are probably very few people who will be able thoroughly to appreciate the author's laborious researches in all sorts of memoirs and transactions of learned societies in order to unearth the material which he has so agreeably condensed. . . . Along with this there is much new matter which, while of great interest to mathematicians, and more especially to men brought up at Cambridge, will be found to throw a good deal of new and important light on the history of education in general.—The Glasgow Herald. Exceedingly interesting to all who care for mathematics. . . . After giving an account of the chief Cambridge Mathematicians and their works in chronological order, Mr. Rouse Ball goes on to deal with the history of tuition and examinations in the University . . . and recounts the steps by which the word "tripos" changed its meaning "from a thing of wood to a man, from a man to a speech, from a speech to two sets of verses, from verses to a sheet of coarse foolscap paper, from a paper to a list of names, and from a list of names to a system of examination."—Never did word undergo so many alterations.—The Literary World. In giving an account of the development of the study of mathematics in the University of Cambridge, and the means by which mathematical proficiency was tested in successive generations, Mr. Ball has taken the novel plan of devoting the first half of his book to . . . the more eminent Cambridge mathematicians, and of reserving to the second part an account of how at various times the subject was 346 taught, and how the result of its study was tested. . . . Very interesting information is given about the work of the students during the different periods, with specimens of problem-papers as far back as 1802. The book is very enjoyable, and gives a capital and accurate digest of many excellent authorities which are not within the reach of the ordinary reader.—The Scots Observer. 347 AN ESSAY ON THE GENESIS, CONTENTS, AND HISTORY OF NEWTON'S "PRINCIPIA" By W.W. ROUSE BALL. [Pp. x + 175. Price 6s. net.] MACMILLAN AND CO. Ltd., LONDON AND NEW YORK. This work contains an account of the successive discoveries of Newton on gravitation, the methods he used, and the history of his researches. It commences with a review of the extant authorities dealing with the subject. In the next two chapters the investigations made in 1666 and 1679 are discussed, some of the documents dealing therewith being here printed for the first time. The fourth chapter is devoted to the investigations made in 1684: these are illustrated by Newton's professorial lectures (of which the original manuscript is extant) of that autumn, and are summed up in the almost unknown memoir of February, 1685, which is here reproduced from Newton's holograph copy. In the two following chapters the details of the preparation from 1685 to 1687 of the Principia are described, and an analysis of the work is given. The seventh chapter comprises an account of the researches of Newton on gravitation subsequent to the publication of the first edition of the Principia, and a sketch of the history of that work. In the last chapter, the extant letters of 1678–1679 between Hooke and Newton, and of those of

1686–1687 between Halley and Newton, are reprinted, and there are also notes on the extant correspondence concerning the production of the second and third editions of the Principia. For the essay which we have before us, Mr Ball should receive the thanks of all those to whom the name of Newton recalls the memory of a great man. The Principia, besides being a lasting monument of Newton's life, is also to-day the classic of our mathematical writings, and will be so for some time to come. . . . The 348 value of the present work is also enhanced by the fact that, besides containing a few as yet unpublished letters, there are collected in its pages quotations from all documents, thus forming a complete summary of everything that is known on the subject. . . . The author is so well known a writer on anything connected with the history of mathematics, that we need make no mention of the thoroughness of the essay, while it would be superfluous for us to add that from beginning to end it is pleasantly written and delightful to read. Those well acquainted with the Principia will find much that will interest them, while those not so fully enlightened will learn much by reading through the account of the origin and history of Newton's greatest work.—Nature. An Essay on Newton's Principia will suggest to many something solely mathematical, and therefore wholly uninteresting. No inference could be more erroneous. The book certainly deals largely in scientific technicalities which will interest experts only; but it also contains much historical information which might attract many who, from laziness or inability, would be very willing to take all its mathematics for granted. Mr. Ball carefully examines the evidence bearing on the development of Newton's great discovery, and supplies the reader with abundant quotations from contemporary authorities. Not the least interesting portion of the book is the appendix, or rather appendices, containing copies of the original documents (mostly letters) to which Mr. Ball refers in his historical criticisms. Several of these bear upon the irritating and unfounded claims of Hooke.—The Athenæum. La savante monographie de M. Ball est rédigée avec beaucoup de soin, et à plusieurs égards elle peut servir de modèle pour des écrits de la même nature.— Bibliotheca Mathematica. Newton's Principia has world-wide fame as a classic of mathematical science. But those who know thoroughly the contents and the history of the book are a select company. It was at one time the purpose of Mr. Ball to prepare a new critical edition of the work, accompanied by a prefatory history and notes, and by an analytical commentary. Mathematicians will regret to hear that there is no prospect in the immediate future of seeing this important book carried to completion by so competent a hand. They will at the same time welcome Mr. Ball's Essay on the Principia for the elucidations which it gives of the process by which Newton's great work originated and took form, and also as an earnest of the completed plan.—The Scotsman. In this essay Mr. Ball presents us with an account highly interesting to mathematicians and natural philosophers of the origin and history of that remarkable product of a

great genius Philosophiae Naturalis Principia Mathematica, 'The Mathematical Principles of Natural Philosophy,' better known by the short term Principia. . . . Mr. Ball's essay is one of extreme interest to students of physical science, and it is sure to be widely read and greatly appreciated.—The Glasgow Herald. To his well-known and scholarly treatises on the History of Mathematics Mr. W.W. Rouse Ball has added An Essay on Newton's Principia. Newton's Principia, as Mr. Ball justly observes, is the classic of English mathematical writings; and this sound, luminous, and laborious essay ought to be the classical account 349 of the Principia. The essay is the outcome of a critical edition of Newton's great work, which Mr. Ball tells us that he once contemplated. It is much to be hoped that he will carry out his intention, for no English mathematician is likely to do the work better or in a more reverent spirit. . . . It is unnecessary to say that Mr. Ball has a complete knowledge of his subject. He writes with an ease and clearness that are rare.—The Scottish Leader. Le volume de M. Rouse Ball renferme tout ce que l'on peut désirer savoir sur l'histoire des Principes; c'est d'ailleurs l'œuvre d'un esprit clair, judicieux, et méthodique.—Bulletin des Sciences Mathématiques. Mr. Ball has put into small space a very great deal of interesting matter, and his book ought to meet with a wide circulation among lovers of Newton and the Principia.—The Academy. Admirers of Mr. W.W. Rouse Ball's Short Account of the History of Mathematics will be glad to receive a detailed study of the history of the Principia from the same hand. This book, like its predecessors, gives a very lucid account of its subject. We find in it an account of Newton's investigations in his earlier years, which are to some extent collected in the tract de Motu (the germ of the Principia) the text of which Mr. Rouse Ball gives us in full. In a later chapter there is a full analysis of the Principia itself, and after that an account of the preparation of the second and third editions. Probably the part of the book which will be found most interesting by the general reader is the account of the correspondence of Newton with Hooke, and with Halley, about the contents or the publication of the Principia. This correspondence is given in full, so far as it is recoverable. Hooke does not appear to advantage in it. He accuses Newton of stealing his ideas. His vain and envious disposition made his own merits appear great in his eyes, and be-dwarfed the work of others, so that he seems to have believed that Newton's great performance was a mere expanding and editing of the ideas of Mr. Hooke—ideas which were meritorious, but after all mere guesses at truth. This, at all events, is the most charitable view we can take of his conduct. Halley, on the contrary, appears as a man to whom we ought to feel most grateful. It almost seems as though Newton's physical insight and extraordinary mathematical powers might have been largely wasted, as was Pascal's rare genius, if it had not been for Halley's single-hearted and self-forgetful efforts to get from his friend's genius all he could for the enlightenment of men. It was probably at his suggestion that the writing of the Principia was

undertaken. When the work was presented to the Royal Society, they undertook its publication, but, being without the necessary funds, the expense fell upon Halley. When Newton, stung by Hooke's accusations, wished to withdraw a part of the work, Halley's tact was required to avert the catastrophe. All the drudgery, worry, and expense fell to his share, and was accepted with the most generous good nature. It will be seen that both the technical student and the general reader may find much to interest him in Mr. Rouse Ball's book.—The Manchester Guardian. Une histoire très bien faite de la genèse du livre immortel de Newton. . . . Le livre de M. Ball est une monographie précieuse sur un point important de l'histoire des mathématiques. Il contribuera à accroître, si c'est possible, la gloire de Newton, en révélant à beaucoup de lecteurs, avec quelle merveilleuse rapid- 350 ité l'illustre géomètre anglais a élevé à la science ce monument immortel, les Principia.—Mathesis. 351 NOTES ON THE HISTORY OF TRINITY COLLEGE, CAMBRIDGE By W.W. ROUSE BALL. [Pp. xiv + 183. Price 2s. 6d. net.] MACMILLAN AND CO. Ltd., LONDON AND NEW YORK. This booklet gives a popular account of the History of Trinity College, Cambridge, and so far as the author knows, it is as yet (1905) the only work published on the subject. It was written mainly for the use of his pupils, and contains such information and gossip about the College and life there in past times as he believed would be interesting to most undergraduates and members of the House. This modest and unpretending little volume seems to us to do more for its subject than many of the more formal volumes . . . treating of the separate colleges of the English universities. . . . In nine short, extremely readable, and truly informing chapters it gives the reader a very vivid account at once of the origin and development of the University of Cambridge, of the rise and gradual supremacy of the colleges, of King's Hall as founded by Edward II, of the suppression of King's Hall by Henry VIII on December 17, 1546, the foundation of Trinity College by royal charter on December 19, and the subsequent fortunes of the premier college of Cambridge. The subject is in a way treated under the successive heads of the college, but this is quite subordinate to the handling and characterisation of the subject under four great periods—namely, that during the Middle Ages, that during the Renaissance, that under the Elizabethan statutes, and that during the last half-century. The colleges arose from the determination of the University to prevent students who were very young from seeking lodging, whether under the wing of one or other of the religious orders—a circumstance which shows this University to have been an essentially lay corporation. Early in the sixteenth century the college had absorbed all the members of the University, and henceforth the University was little more than the degree-granting body to students who lived and moved and had their educational being under the colleges. . . . The University finally took the form of an aggregate of separate and independent corporations, with a federal constitution analogous in a rough sort of way to that of the United States of

America, 352 and different from similar corporations at Paris by the fact that these latter were always subject to University supervision. . . . There is a good account of the effort now going on to re-assert the University at the expense of the colleges. No one who begins Mr. Ball's book will lay it down till he has read it from beginning to end.—The Glasgow Herald. It is a sign of the times, and a very satisfactory one, when . . . a tutor . . . takes the trouble to make the history of his college known to his pupils. Considering the lack of good books about the Universities, we may thank Mr. Ball that he has been good enough to print for a larger circle. Though he modestly calls his book only "Notes," yet it is eminently readable, and there is plenty of information, as well as abundance of good stories, in its pages.—The Oxford Magazine. Mr. Ball has put not only the pupils for whom he compiled these notes, but the large world of Trinity men, under a great obligation by this compendious but lucid and interesting history of the society to whose service he is devoted. The value of his contribution to our knowledge is increased by the extreme simplicity with which he tells his story, and the very suggestive details which, without much comment, he has selected, with admirable discernment, out of the wealth of materials at his disposal. His initial account of the development of the University is brief but extremely clear, presenting us with facts rather than theories, but establishing, with much distinctness, the essential difference between the hostels, out of which the more modern colleges grew, and that monastic life which poorer students were often tempted to join.—The Guardian. An interesting and valuable book. . . . It is described by its author as "little more than an orderly transcript" of what, as a Fellow and Tutor of the College, he has been accustomed to tell his pupils. But while it does not pretend either to the form or to the exhaustiveness of a set history, it is scholarly enough to rank as an authority, and far more interesting and readable than most academic histories are. It gives an instructive sketch of the development of the University and of the particular history of Trinity, noting its rise and policy in the earlier centuries of its existence, until, under the misrule of Bentley, it came into a state of disorder which nearly resulted in its dissolution. The subsequent rise of the College and its position in what Mr. Ball calls the Victorian renaissance, are drawn in lines no less suggestive; and the book, as a whole, cannot fail to be welcome to every one who is closely interested in the progress of the College.—The Scotsman. Mr. Ball has succeeded very well in giving in this little volume just what an intelligent undergraduate ought and probably often does desire to know about the buildings and the history of his College. . . . The debt of the "royal and religious foundation" to Henry VIII is explained with fulness, and there is much interesting matter as to the manner of life and the expenses of students in the sixteenth century.—The Manchester Guardian. various formats will be found in: https://www.gutenberg.org/2/6/8/3/26839/ Updated editions will replace the previous one—the old editions will be renamed. Creating the works from print editions not protected by U.S. copyright law means that no one owns a United States copyright in these works, so the Foundation (and you!) can copy and distribute it in the United States without permission and without paying copyright royalties. Special rules, set forth in the General Terms of Use part of this license, apply to copying and distributing Project Gutenberg-tm electronic works to protect the PROJECT GUTENBERG-tm concept and trademark. Project Gutenberg is a registered trademark, and may not be used if you charge for an eBook, except by following the terms of the trademark license, including paying royalties for use of the Project Gutenberg trademark. If you do not charge anything for copies of this eBook, complying with the trademark license is very easy. You may use this eBook for nearly any purpose such as creation of derivative works, reports, performances and research. Project Gutenberg eBooks may be modified and printed and given away—you may do practically ANYTHING in the United States with eBooks not protected by U.S. copyright law. Redistribution is subject to the trademark license, especially commercial redistribution. START: FULL LICENSE THE FULL PROJECT GUTENBERG LICENSE PLEASE READ THIS BEFORE YOU DISTRIBUTE OR USE THIS WORK To protect the Project Gutenberg-tm mission of promoting the free distribution of electronic works, by using or distributing this work (or any other work associated in any way with the phrase “Project Gutenberg”), you agree to comply with all the terms of the Full Project Gutenberg-tm License available with this file or online at www.gutenberg.org/license. Section 1. General Terms of Use and Redistributing Project Gutenberg-tm electronic works 1.A. By reading or using any part of this Project Gutenberg-tm electronic work, you indicate that you have read, understand, agree to and accept all the terms of this license and intellectual property (trademark/copyright) agreement. If you do not agree to abide by all the terms of this agreement, you must cease using and return or destroy all copies of Project Gutenberg-tm electronic works in your possession. If you paid a fee for obtaining a copy of or access to a Project Gutenberg-tm electronic work and you do not agree to be bound by the terms of this agreement, you may obtain a refund from the person or entity to whom you paid the fee as set forth in paragraph 1.E.8. 1.B. “Project Gutenberg” is a registered trademark. It may only be 354 LICENSING. used on or associated in any way with an electronic work by people who agree to be bound by the terms of this agreement. There are a few things that you can do with most Project Gutenberg-tm electronic works even without complying with the full terms of this agreement. See paragraph 1.C below. There are a lot of things you can do with Project Gutenberg-tm electronic works if you follow the terms of this agreement and help preserve free future access to Project Gutenberg-tm electronic works. See paragraph 1.E below. 1.C. The Project

Gutenberg Literary Archive Foundation (“the Foundation” or PGLAF), owns a compilation copyright in the collection of Project Gutenberg-tm electronic works. Nearly all the individual works in the collection are in the public domain in the United States. If an individual work is unprotected by copyright law in the United States and you are located in the United States, we do not claim a right to prevent you from copying, distributing, performing, displaying or creating derivative works based on the work as long as all references to Project Gutenberg are removed. Of course, we hope that you will support the Project Gutenberg-tm mission of promoting free access to electronic works by freely sharing Project Gutenberg-tm works in compliance with the terms of this agreement for keeping the Project Gutenberg-tm name associated with the work. You can easily comply with the terms of this agreement by keeping this work in the same format with its attached full Project Gutenberg-tm License when you share it without charge with others. 1.D. The copyright laws of the place where you are located also govern what you can do with this work. Copyright laws in most countries are in a constant state of change. If you are outside the United States, check the laws of your country in addition to the terms of this agreement before downloading, copying, displaying, performing, distributing or creating derivative works based on this work or any other Project Gutenberg-tm work. The Foundation makes no representations concerning the copyright status of any work in any country other than the United States. 1.E. Unless you have removed all references to Project Gutenberg: 1.E.1. The following sentence, with active links to, or other immediate access to, the full Project Gutenberg-tm License must appear prominently whenever any copy of a Project Gutenberg-tm work (any work on which the phrase “Project Gutenberg” appears, or with which the phrase “Project Gutenberg” is associated) is accessed, displayed, performed, viewed, copied or distributed: This eBook is for the use of anyone anywhere in the United States and most other parts of the world at no cost and with almost no restrictions whatsoever. You may copy it, give it away or re-use it under the terms of the Project Gutenberg License included with this eBook or online at www.gutenberg.org. If you are not located in the United States, you will have to check the laws of the country where you are located before using this eBook. 1.E.2. If an individual Project Gutenberg-tm electronic work is derived from texts not protected by U.S. copyright law (does not contain a notice indicating that it is posted with permission of the copyright holder), the work can be copied and distributed to anyone in the United States without paying any fees or charges. If you are LICENSING. 355 redistributing or providing access to a work with the phrase “Project Gutenberg” associated with or appearing on the work, you must comply either with the requirements of paragraphs 1.E.1 through 1.E.7 or obtain permission for the use of the work and the Project Gutenberg-tm trademark as set forth in paragraphs 1.E.8 or 1.E.9. 1.E.3. If an individual Project Gutenberg-tm electronic work is posted with the

permission of the copyright holder, your use and distribution must comply with both paragraphs 1.E.1 through 1.E.7 and any additional terms imposed by the copyright holder. Additional terms will be linked to the Project Gutenberg-tm License for all works posted with the permission of the copyright holder found at the beginning of this work. 1.E.4. Do not unlink or detach or remove the full Project Gutenberg-tm License terms from this work, or any files containing a part of this work or any other work associated with Project Gutenberg-tm. 1.E.5. Do not copy, display, perform, distribute or redistribute this electronic work, or any part of this electronic work, without prominently displaying the sentence set forth in paragraph 1.E.1 with active links or immediate access to the full terms of the Project Gutenberg-tm License. 1.E.6. You may convert to and distribute this work in any binary, compressed, marked up, nonproprietary or proprietary form, including any word processing or hypertext form. However, if you provide access to or distribute copies of a Project Gutenberg-tm work in a format other than “Plain Vanilla ASCII” or other format used in the official version posted on the official Project Gutenberg-tm website (www.gutenberg.org), you must, at no additional cost, fee or expense to the user, provide a copy, a means of exporting a copy, or a means of obtaining a copy upon request, of the work in its original “Plain Vanilla ASCII” or other form. Any alternate format must include the full Project Gutenberg-tm License as specified in paragraph 1.E.1. 1.E.7. Do not charge a fee for access to, viewing, displaying, performing, copying or distributing any Project Gutenberg-tm works unless you comply with paragraph 1.E.8 or 1.E.9. 1.E.8. You may charge a reasonable fee for copies of or providing access to or distributing Project Gutenberg-tm electronic works provided that: * You pay a royalty fee of 20% of the gross profits you derive from the use of Project Gutenberg-tm works calculated using the method you already use to calculate your applicable taxes. The fee is owed to the owner of the Project Gutenberg-tm trademark, but he has agreed to donate royalties under this paragraph to the Project Gutenberg Literary Archive Foundation. Royalty payments must be paid within 60 days following each date on which you prepare (or are legally required to prepare) your periodic tax returns. Royalty payments should be clearly marked as such and sent to the Project Gutenberg Literary Archive Foundation at the address specified in Section 4, “Information about donations to the Project Gutenberg Literary Archive Foundation.” * You provide a full refund of any money paid by a user who notifies 356 LICENSING. you in writing (or by email) within 30 days of receipt that s/he does not agree to the terms of the full Project Gutenberg-tm License. You must require such a user to return or destroy all copies of the works possessed in a physical medium and discontinue all use of and all access to other copies of Project Gutenberg-tm works. * You provide, in accordance with paragraph 1.F.3, a full refund of any money paid for a work or a replacement copy, if a defect in the electronic work is discovered and reported to you

within 90 days of receipt of the work. * You comply with all other terms of this agreement for free distribution of Project Gutenberg-tm works. 1.E.9. If you wish to charge a fee or distribute a Project Gutenberg-tm electronic work or group of works on different terms than are set forth in this agreement, you must obtain permission in writing from the Project Gutenberg Literary Archive Foundation, the manager of the Project Gutenberg-tm trademark. Contact the Foundation as set forth in Section 3 below. 1.F. 1.F.1. Project Gutenberg volunteers and employees expend considerable effort to identify, do copyright research on, transcribe and proofread works not protected by U.S. copyright law in creating the Project Gutenberg-tm collection. Despite these efforts, Project Gutenberg-tm electronic works, and the medium on which they may be stored, may contain “Defects,” such as, but not limited to, incomplete, inaccurate or corrupt data, transcription errors, a copyright or other intellectual property infringement, a defective or damaged disk or other medium, a computer virus, or computer codes that damage or cannot be read by your equipment. 1.F.2. LIMITED WARRANTY, DISCLAIMER OF DAMAGES - Except for the “Right of Replacement or Refund” described in paragraph 1.F.3, the Project Gutenberg Literary Archive Foundation, the owner of the Project Gutenberg-tm trademark, and any other party distributing a Project Gutenberg-tm electronic work under this agreement, disclaim all liability to you for damages, costs and expenses, including legal fees. YOU AGREE THAT YOU HAVE NO REMEDIES FOR NEGLIGENCE, STRICT LIABILITY, BREACH OF WARRANTY OR BREACH OF CONTRACT EXCEPT THOSE PROVIDED IN PARAGRAPH 1.F.3. YOU AGREE THAT THE FOUNDATION, THE TRADEMARK OWNER, AND ANY DISTRIBUTOR UNDER THIS AGREEMENT WILL NOT BE LIABLE TO YOU FOR ACTUAL, DIRECT, INDIRECT, CONSEQUENTIAL, PUNITIVE OR INCIDENTAL DAMAGES EVEN IF YOU GIVE NOTICE OF THE POSSIBILITY OF SUCH DAMAGE. 1.F.3. LIMITED RIGHT OF REPLACEMENT OR REFUND - If you discover a defect in this electronic work within 90 days of receiving it, you can receive a refund of the money (if any) you paid for it by sending a written explanation to the person you received the work from. If you received the work on a physical medium, you must return the medium with your written explanation. The person or entity that provided you with the defective work may elect to provide a replacement copy in lieu of a refund. If you received the work electronically, the person or entity providing it to you may choose to give you a second LICENSING. 357 opportunity to receive the work electronically in lieu of a refund. If the second copy is also defective, you may demand a refund in writing without further opportunities to fix the problem. 1.F.4. Except for the limited right of replacement or refund set forth in paragraph 1.F.3, this work is provided to you—‘AS-IS’, WITH NO OTHER WARRANTIES OF ANY KIND, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO WARRANTIES OF MERCHANTABILITY OR FITNESS FOR ANY PURPOSE. 1.F.5. Some states do not allow

disclaimers of certain implied warranties or the exclusion or limitation of certain types of damages. If any disclaimer or limitation set forth in this agreement violates the law of the state applicable to this agreement, the agreement shall be interpreted to make the maximum disclaimer or limitation permitted by the applicable state law. The invalidity or unenforceability of any provision of this agreement shall not void the remaining provisions. 1.F.6. INDEMNITY - You agree to indemnify and hold the Foundation, the trademark owner, any agent or employee of the Foundation, anyone providing copies of Project Gutenberg-tm electronic works in accordance with this agreement, and any volunteers associated with the production, promotion and distribution of Project Gutenberg-tm electronic works, harmless from all liability, costs and expenses, including legal fees, that arise directly or indirectly from any of the following which you do or cause to occur: (a) distribution of this or any Project Gutenberg-tm work, (b) alteration, modification, or additions or deletions to any Project Gutenberg-tm work, and (c) any Defect you cause. Section 2. Information about the Mission of Project Gutenberg-tm Project Gutenberg-tm is synonymous with the free distribution of electronic works in formats readable by the widest variety of computers including obsolete, old, middle-aged and new computers. It exists because of the efforts of hundreds of volunteers and donations from people in all walks of life. Volunteers and financial support to provide volunteers with the assistance they need are critical to reaching Project Gutenberg-tm's goals and ensuring that the Project Gutenberg-tm collection will remain freely available for generations to come. In 2001, the Project Gutenberg Literary Archive Foundation was created to provide a secure and permanent future for Project Gutenberg-tm and future generations. To learn more about the Project Gutenberg Literary Archive Foundation and how your efforts and donations can help, see Sections 3 and 4 and the Foundation information page at www.gutenberg.org Section 3. Information about the Project Gutenberg Literary Archive Foundation The Project Gutenberg Literary Archive Foundation is a non-profit 501(c)(3) educational corporation organized under the laws of the state of Mississippi and granted tax exempt status by the Internal Revenue Service. The Foundation's EIN or federal tax identification number is 64-6221541. Contributions to the Project Gutenberg Literary Archive Foundation are tax deductible to the full extent permitted by 358 LICENSING. U.S. federal laws and your state's laws. The Foundation's business office is located at 809 North 1500 West, Salt Lake City, UT 84116, (801) 596-1887. Email contact links and up to date contact information can be found at the Foundation's website and official page at www.gutenberg.org/contact Section 4. Information about Donations to the Project Gutenberg Literary Archive Foundation Project Gutenberg-tm depends upon and cannot survive without widespread public support and donations to carry out its mission of increasing the number of public domain and licensed works that can be freely distributed in machine-readable form accessible by the

widest array of equipment including outdated equipment. Many small donations ($1 to $5,000) are particularly important to maintaining tax exempt status with the IRS. The Foundation is committed to complying with the laws regulating charities and charitable donations in all 50 states of the United States. Compliance requirements are not uniform and it takes a considerable effort, much paperwork and many fees to meet and keep up with these requirements. We do not solicit donations in locations where we have not received written confirmation of compliance. To SEND DONATIONS or determine the status of compliance for any particular state visit www.gutenberg.org/donate While we cannot and do not solicit contributions from states where we have not met the solicitation requirements, we know of no prohibition against accepting unsolicited donations from donors in such states who approach us with offers to donate. International donations are gratefully accepted, but we cannot make any statements concerning tax treatment of donations received from outside the United States. U.S. laws alone swamp our small staff. Please check the Project Gutenberg web pages for current donation methods and addresses. Donations are accepted in a number of other ways including checks, online payments and credit card donations. To donate, please visit: www.gutenberg.org/donate Section 5. General Information About Project Gutenberg-tm electronic works Professor Michael S. Hart was the originator of the Project Gutenberg-tm concept of a library of electronic works that could be freely shared with anyone. For forty years, he produced and distributed Project Gutenberg-tm eBooks with only a loose network of volunteer support. Project Gutenberg-tm eBooks are often created from several printed editions, all of which are confirmed as not protected by copyright in the U.S. unless a copyright notice is included. Thus, we do not necessarily keep eBooks in compliance with any particular paper edition. Most people start at our website which has the main PG search facility: www.gutenberg.org LICENSING. 359 This website includes information about Project Gutenberg-tm, including how to make donations to the Project Gutenberg Literary Archive Foundation, how to help produce our new eBooks, and how to subscribe to our email newsletter to hear about new eBooks.

PREFIXED TO THE LIVES OF ELIAS ASHMOLE & WILLIAM LILLY.

In 1 vol. 8vo. 1772.

Zaid n. adwan

Although we cannot, with justice, compare Elias Ashmole to that excellent Antiquary John Leland, or William Lilly to the learned and indefatigable Thomas Hearne; yet I think we may fairly rank them with such writers as honest Anthony Wood, whose Diary *greatly resembles that of his cotemporary, and intimate friend, Elias Ashmole.*

Some anecdotes, connected with affairs of state; many particulars relating to illustrious persons, and antient and noble families; several occurrences in which the Public is interested, and other matters of a more private nature, can only be found in works of this kind. History cannot stoop to the meanness of examining the materials of which Memoirs *are generally composed.*

And yet the pleasure and benefit resulting from such books are manifest to every reader.

I hope the admirers of the very laborious Thomas Hearne will pardon me, if I should venture to give it as my opinion, and with much deference to their judgment, that William Lilly's Life and Death of Charles the first *contains more useful matter of instruction, as well as more splendid and striking occurrences, than are to be found in several of those monkish volumes published by that learned Oxonian.*

Lilly affords us many curious particulars relating to the life of that unfortunate Prince, which are no where else to be found. In delineating the character of Charles, he seems dispassionate and impartial, and indeed it agrees perfectly with the general portraiture of him, as it is drawn by our most authentic historians.

The History of Lilly's Life and Times *is certainly one of the most entertaining narratives in our language. With respect to the science he professed of calculating nativities, casting figures, the prediction of events, and other appendages of astrology, he would fain make us think that he was a very solemn and serious believer. Indeed, such is the manner of telling his story, that sometimes the reader may possibly be*

induced to suppose Lilly rather an enthusiast than an impostor. He relates many anecdotes of the pretenders to foretell events, raise spirits, and other impostures, with such seeming candor, and with such an artless simplicity of style, that we are almost persuaded to take his word when he protests such an inviolable respect to truth and sincerity.

The powerful genius of Shakespeare could carry him triumphantly through subjects the most unpromising, and fables the most improbable: we therefore cannot wonder at the success of such of his plays, where the magic of witches and the incantation of spirits are described, or where the power of fairies is introduced; when such was the credulity of the times respecting these imaginary beings, and when that belief was made a science of, and kept alive by artful and superstitious, knavish, and enthusiastic teachers; what Lilly relates of these people, considered only as matter of fact, is surely very curious.

To conclude; I know no record but this where we can find so just and so entertaining a History of Doctor Dee, Doctor Forman, Booker, Winder, Kelly, Evans, (Lilly's Master,) the famous William Poole, and Captain Bubb Fiske, Sarah Shelborne, and many others.

To these we may add, the uncommon effects of the Crystal, the appearance of Queen Mabb, and other strange and miraculous operations, which owe their origin to folly, curiosity, superstition, bigotry, and imposture.{7}

THE LIFE OF WILLIAM LILLY, STUDENT IN ASTROLOGY.

Wrote by himself in the 66th Year of his Age, at Hersham, in the Parish of Walton-upon-Thames, in the County of Surry. *Propria Manu.*

I[1] was born in the county of Leicester, in an obscure town, in the north-west borders thereof, called Diseworth, seven miles south of the town of Derby, one mile from Castle-Donnington, a town of great rudeness, wherein it is not remembered that any of {8}the farmers thereof did ever educate any of their sons to learning, only my grandfather sent his younger son to Cambridge, whose {9}name was Robert Lilly, and died Vicar of Cambden in Gloucestershire, about 1640.

Footnote 1:(return)

"William Lilly was a prominent, and, in the opinion of many of his cotemporaries, a very important personage in the most eventful period of English history. He was a principal actor in the farcical scenes which diversified the bloody tragedy of civil war; and while the King and the Parliament were striving for mastery in the field, he was deciding their destinies in the closet. The weak and the credulous of both parties, who sought to be instructed in 'destiny's dark counsels,' flocked to consult the 'wily Archimage,' who, with exemplary impartiality, meted out victory and good fortune to his clients, according to the extent of their faith, and the weight of their purses. A few profane Cavaliers might make his name the burthen of their *malignant* rhymes—a few of the more scrupulous among the *Saints* might keep aloof in sanctified abhorrence of the 'Stygian sophister'—but the great majority of the people lent a willing and reverential ear to his prophecies and prognostications. Nothing was too high or too low—too mighty or too insignificant, for the grasp of his genius. The stars, his informants, were as communicative on the most trivial as on the most important subjects. If a scheme was set on foot to rescue the king, or to retrieve a stray trinket—to restore the royal authority, or to make a frail damsel an honest woman—to cure the nation of anarchy, or a lap-dog of a surfeit, William Lilly was the oracle to be consulted. His *almanacks* were spelled over in the tavern and quoted in the senate; they nerved the arm of the soldier, and rounded the periods of the orator. The fashionable beauty, dashing along in her calash from St. James's or the Mall, and the prim, starched dame, from Watling-street or Bucklersbury, with a staid foot-boy, in a plush jerkin, plodding behind her—the reigning toast among 'the men of wit about town,' and the leading groaner in a tabernacle concert—glided alternately into the study of the trusty wizard, and poured into his attentive ear strange tales of love, or trade, or treason. The Roundhead stalked in at one door, whilst the Cavalier was hurried out at the other.

"The *Confessions* of a man so variously consulted and trusted, if written with the candour of a Cardan or a Rousseau, would indeed be invaluable. The *Memoirs of William Lilly*, though deficient in this essential ingredient, yet contain a variety of curious and interesting anecdotes of himself and his cotemporaries,

which, where the vanity of the writer, or the truth of his art, is not concerned, may be received with implicit credence.

"The simplicity and apparent candour of his narrative might induce a hasty reader of this book to believe him a well-meaning but somewhat silly personage, the dupe of his own speculations—the deceiver of himself as well as of others. But an attentive examination of the events of his life, even as recorded by himself, will not warrant so favourable an interpretation. His systematic and successful attention to his own interest—his dexterity in keeping on 'the windy side of the law'—his perfect political pliability—and his presence of mind and fertility of resources when entangled in difficulties—indicate an accomplished impostor, not a crazy enthusiast. It is very possible and probable, that, at the outset of his career, he was a real believer in the truth and lawfulness of his art, and that he afterwards felt no inclination to part with so pleasant and so profitable a delusion: like his patron, Cromwell, whose early fanaticism subsided into hypocrisy, he carefully retained his folly as a cloak for his knavery. Of his success in deception, the present narrative exhibits abundant proofs. The number of his dupes was not confined to the vulgar and illiterate, but included individuals of real worth and learning, of hostile parties and sects, who courted his acquaintance and respected his predictions. His proceedings were deemed of sufficient importance to be twice made the subject of a parliamentary inquiry; and even after the Restoration—when a little more scepticism, if not more wisdom, might have been expected—we find him examined by a Committee of the House of Commons, respecting his fore-knowledge of the great fire of London. We know not whether it 'should more move our anger or our mirth,' to see an assemblage of British Senators—the cotemporaries of Hampden and Falkland—of Milton and Clarendon—in an age which roused into action so many and such mighty energies—gravely engaged in ascertaining the causes of a great national calamity, from the prescience of a knavish fortuneteller, and puzzling their wisdoms to interpret the symbolical flames, which blazed in the mis-shapen wood-cuts of his oracular publications.

"As a set-off against these honours may be mentioned, the virulent and unceasing attacks of almost all the party scribblers of the day; but their abuse he shared in common with men, whose talents and virtues have outlived the malice of their cotemporaries, and

'Whose honours with increase of ages grow,
As streams roll down, enlarging as they flow.'"

Retrospective Review, Vol. ii. p. 51.

The town of Diseworth did formerly belong {10}long unto the Lord Seagrave, for there is one record in the hands of my cousin Melborn Williamson, which mentions one acre of land {11}abutting north upon the gates of the Lord Seagrave; and there is one close, called Hall-close, wherein the ruins of some ancient {12}buildings appear, and particularly where the dove-house stood; and there is also the ruins of decayed fish-ponds and other outhouses. This town came at length to be the inheritance of Margaret, Countess of Richmond, mother of Henry VII. which {13}Margaret gave this town and lordship of Diseworth unto Christ's College in Cambridge, the Master and Fellows whereof have ever since, and at present, enjoy and possess it.

In the church of this town there is but one monument, and that is a white marble stone, now almost broken to pieces, which was placed there by Robert Lilly, my grandfather, in memory of Jane his wife, the daughter of Mr. Poole of Dalby, in the same county, a family now quite extinguished. My grandmother's brother was Mr. Henry Poole, one of the Knights of Rhodes, or Templars, who being a soldier at Rhodes at the taking thereof by Solyman the Magnificent, and escaping with his life, came afterwards to England, and married the Lady Parron or Perham, of Oxfordshire, and was called, during his life, Sir Henry Poole. William {14}Poole the Astrologer knew him very well, and remembers him to have been a very tall person, and reputed of great strength in his younger years.

The impropriation of this town of Diseworth was formerly the inheritance of three sisters, whereof two became votaries; one in the nunnery of Langly in the parish of Diseworth, valued at the suppression, I mean the whole nunnery, at thirty-two pounds per annum, and this sister's part is yet enjoyed by the family of the Grayes, who now, and for some years past, have the enjoyment and possession of all the lands formerly belonging to the nunnery in the parish of Diseworth, and are at present of the yearly value of three hundred and fifty pounds per annum. One of the sisters gave her part of

the great tithes unto a religious house in Bredon upon the Hill; and, as the inhabitants {15}report, became a religious person afterwards.

The third sister married, and her part of the tithes in succeeding ages became the Earl of Huntingdon's, who not many years since sold it to one of his servants.

The donation of the vicarage is in the gift of the Grayes of Langley, unto whom they pay yearly, (I mean unto the Vicar) as I am informed, six pounds per annum. Very lately some charitable citizens have purchased one-third portion of the tithes, and given it for a maintenance of a preaching minister, and it is now of the value of about fifty pounds per annum.

There have been two hermitages in this parish; the last hermit was well remembered by one Thomas Cooke, a very ancient inhabitant, who in my younger years acquainted me therewith.

{16}

This town of Diseworth is divided into three parishes; one part belongs under Locington, in which part standeth my father's house, over-against the west end of the steeple, in which I was born: some other farms are in the parish of Bredon, the rest in the parish of Diseworth.

In this town, but in the parish of Lockington, was I born, the first day of May 1602.

My father's name was William Lilly, son of Robert, the son of Robert, the son of Rowland, &c. My mother was Alice, the daughter of Edward Barham, of Fiskerton Mills, in Nottinghamshire, two miles from Newark upon Trent: this Edward Barham was born in Norwich, and well remembered the rebellion of Kett the Tanner, in the days of Edward VI.

Our family have continued many ages in this town as yeomen; besides the farm my {17}father and his ancestors lived in, both my father and grandfather had much free land, and many houses in the town, not belonging to the college, as the farm wherein they were all born doth, and is now at this present of the value of forty pounds per annum, and in possession of my brother's son; but the freehold land and houses, formerly purchased by my ancestors, were all sold by my grandfather and father; so that now our family depend wholly upon a college lease. Of my infancy I can speak little, only I do remember that in the fourth year of my age I had the measles.

I was, during my minority, put to learn at such schools, and of such masters, as the rudeness of the place and country afforded; my mother intending I should be a scholar from my infancy, seeing my father's back-slidings in the world, and no hopes by plain {18}husbandry to recruit a decayed estate; therefore upon Trinity Tuesday, 1613, my father had me to Ashby de la Zouch, to be instructed by one Mr. John Brinsley; one, in those times, of great abilities for instruction of youth in the Latin and Greek tongues; he was very severe in his life and conversation, and did breed up many scholars for the universities: in religion he was a strict Puritan, not conformable wholly to the ceremonies of the Church of England. In this town of Ashby de la Zouch, for many years together, Mr. Arthur Hildersham exercised his ministry at my being there; and all the while I continued at Ashby, he was silenced. This is that famous Hildersham, who left behind him a commentary on the fifty-first psalm; as also many sermons upon the fourth of John, both which are printed; he was an excellent textuary, of exemplary life, {19}pleasant in discourse, a strong enemy to the Brownists, and dissented not from the Church of England in any article of faith, but only about wearing the surplice, baptizing with the cross, and kneeling at the sacrament; most of the people in town were directed by his judgement, and so continued, and yet do continue presbyterianly affected; for when the Lord of Loughborough in 1642, 1643, 1644, and 1645, had his garrison in that town, if by chance at any time any troops of horse had lodged within

the town, though they came late at night to their quarters; yet would one or other of the town presently give Sir John Gell of Derby notice, so that ere next morning most of his Majesty's troops were seized in their lodgings, which moved the Lord of Loughborough merrily to say, there was not a fart let in Ashby, but it was presently carried to Derby.

{20}

The several authors I there learned were these, viz. *Sententiæ Pueriles, Cato, Corderius, Æsop's Fables, Tully's Offices, Ovid de Tristibus*; lastly, *Virgil*, then *Horace*; as also *Camden's Greek Grammar, Theognis* and *Homer's Iliads*: I was only entered into *Udall's Hebrew Grammar*; he never taught logick, but often would say it was fit to be learned in the universities.

In the fourteenth year of my age, by a fellow scholar of swarth, black complexion, I had like to have my right eye beaten out as we were at play; the same year, about Michaelmas, I got a surfeit, and thereupon a fever, by eating beech-nuts.

In the sixteenth year of my age I was exceedingly troubled in my dreams concerning my salvation and damnation, and also concerning the safety and destruction of the souls of my father and mother; in the nights {21}I frequently wept, prayed and mourned, for fear my sins might offend God.

In the seventeenth year of my age my mother died.

In the eighteenth year of my age my master Brinsley was enforced from keeping school, being persecuted by the Bishop's officers; he came to London, and then lectured in London, where he afterwards died. In this year, by reason of my father's poverty, I was also enforced to leave school, and so came to my father's house, where I lived in much penury for one year, and taught school one quarter of a year, until God's providence provided better for me.

For the two last years of my being at school, I was of the highest form in the school, and chiefest of that form; I could then speak Latin as well as English; could make extempore verses upon any theme; {22}all kinds of verses, hexameter, pentameter, phaleuciacks, iambicks, sapphicks, &c. so that if any scholars from remote schools came to dispute, I was ringleader to dispute with them; I could cap verses, &c. If any minister came to examine us, I was brought forth against him, nor would I argue with him unless in the Latin tongue, which I found few of them could well speak without breaking Priscian's head; which, if once they did, I would complain to my master, *Non bene intelligit linguam Latinam, nec prorsus loquitur*. In the derivation of words, I found most of them defective, nor indeed were any of them good grammarians: all and every of those scholars who were of my form and standing, went to Cambridge and proved excellent divines, only poor I, William Lilly, was not so happy; fortune then frowning upon father's present condition, he {23}not in any capacity to maintain me at the university.

OF THE MANNER HOW I CAME UNTO LONDON.

Worthy sir, I take much delight to recount unto you, even all and every circumstance of my life, whether good, moderate, or evil; *Deo gloria*.

My father had one Samuel Smatty for his Attorney, unto whom I went sundry times with letters, who perceiving I was a scholar, and that I lived miserably in the country, losing my time, nor any ways likely to do better, if I continued there; pitying my condition, he sent word for me to come and speak with him, and told me that he had lately been at London, where there was a gentleman wanted a youth, to attend him and his wife, who could write, &c.

{24}

I acquainted my father with it, who was very willing to be rid of me, for I could not work, drive the plough, or endure any country labour; my father oft would say, I was good for nothing.

I had only twenty shillings, and no more, to buy me a new suit, hose, doublet, &c. my doublet was fustian: I repaired to Mr. Smatty, when I was accoutred, for a letter to my master, which he gave me.

Upon Monday, April 3, 1620, I departed from Diseworth, and came to Leicester: but I must acquaint you, that before I came away I visited my friends, amongst whom I had given me about ten shillings, which was a great comfort unto me. On Tuesday, April the 4th, I took leave of my father, then in Leicester gaol for debt, and came along with Bradshaw the carrier, the same person with whom many of the {25}Duke of Buckingham's kindred had come up with. Hark how the waggons crack with their rich lading! It was a very stormy week, cold and uncomfortable: I footed it all along; we could not reach London until Palm-Sunday, the 9th of April, about half an hour after three in the afternoon, at which time we entered Smithfield. When I had gratified the carrier and his servants, I had seven shillings and sixpence left, and no more; one suit of cloaths upon my back, two shirts, three bands, one pair of shoes, and as many stockings. Upon the delivery of my letter my master entertained me, and next day bought me a new cloak, of which you may imagine (good Esquire) whether I was not proud of; besides, I saw and eat good white bread, contrary to our diet in Leicestershire. My master's name was Gilbert Wright, born at {26}Market Bosworth in Leicestershire; my mistress was born at Ashby de la Zouch, in the same county, and in the town where I had gone to school. This Gilbert Wright could neither write nor read: he lived upon his annual rents, was of no calling or profession; he had for many years been servant to the Lady Pawlet in Hertfordshire; and when Serjeant Puckering was made Lord keeper, he made him keeper of his lodgings at Whitehall. When Sir Thomas Egerton was made

Lord Chancellor, he entertained him in the same place; and when he married a widow in Newgate Market, the Lord Chancellor recommended him to the company of Salters, London, to admit him into their company, and so they did, and my master in 1624, was master of that company; he was a man of excellent natural parts, and would {27}speak publickly upon any occasion very rationally and to the purpose. I write this, that the world may know he was no taylor, or myself of that or any other calling or profession: my work was to go before my master to church; to attend my master when he went abroad; to make clean his shoes; sweep the street; help to drive bucks when he washed; fetch water in a tub from the Thames: I have helped to carry eighteen tubs of water in one morning; weed the garden; all manner of drudgeries I willingly performed; scrape trenchers, &c. If I had any profession, it was of this nature: I should never have denied being a taylor, had I been one; for there is no calling so base, which by God's mercy may not afford a livelihood; and had not my master entertained me, I would have been of a very mean profession ere I would have {28}returned into the country again; so here ends the actions of eighteen years of my life.

My master married his second wife for her estate; she was competently rich; she married him for considerations he performed not, (nocturnal society) so that they lived very uncomfortably; she was about seventy years of age, he sixty-six or more; yet never was any woman more jealous of a husband than she; insomuch, that whensoever he went into London, she was confident of his going to women; by those means my life was the more uncomfortable, it being very difficult to please two such opposite natures: however, as to the things of this world I had enough, and endured their discontents with much sereneness. My mistress was very curious to know of such as were then called cunning or wise {29}men, whether she should bury her husband? She frequently visited such persons, and this occasion begot in me a little desire to learn something that way, but wanting money to buy books, I laid aside these motions, and endeavoured to please both master and mistress.

OF MY MISTRESS'S DEATH, AND OCCASION THEREOF BY MEANS OF A CANCER IN HER BREAST.

In 1622 she complained of a pain in her left breast, whereon there appeared at first a hard knob no bigger than a small pea; it increased in a little time very much, was very hard, and sometimes would look very red; she took advice of surgeons, had oils, sear-cloths, plates of lead, and what not: in 1623 it grew very big, and spread all {30}over her breast; then for many weeks poultices were applied to it, which in continuance of time broke the skin, and then abundance of watery thin stuff came from it, but nothing else; at length the matter came to suppuration, but never any great store issued forth; it was exceeding noisome and painful; from the beginning of it until she died, she would permit no surgeon to dress it but only myself; I applied every thing unto it, and her pains were so great the winter before she died, that I have been called out of my bed two or three times in one night to dress it and change plaisters. In 1624 by degrees, with scissars, I cut all the whole breast away, I mean the sinews, nerves, &c. In one fortnight, or little more, it appeared, as it were, mere flesh, all raw, so that she could scarce endure any unguent to be applied.

{31}

I remember there was a great cleft through the middle of the breast, which when that fully appeared she died, which was in September 1624; my master being then in the country, his kindred in London would willingly have had mourning for her; but by advice of an especial friend of his I contradicted them; nor would I permit them to look into any chest or trunk in the house. She was decently buried, and so fond of me in the time of her sickness, she would never permit me out of her chamber, gave me five pounds in old gold, and sent me unto a private trunk of her's at a friend's house, where she had one hundred pounds in gold; she bid me bring it away and take it, but when I opened the trunk I found nothing therein; for a kinsman of hers had been there a few

days before, and carried all away: she was in a great passion at my relating thereof, because {32}she could not gratify my pains in all her sickness, advised me to help myself, when she was gone, out of my master's goods, which I never did.

Courteous Esquire, be not weary of reading hereof, or what followeth.

When my mistress died, she had under her arm-hole a small scarlet bag full of many things, which, one that was there delivered unto me. There was in this bag several sigils, some of Jupiter in Trine, others of the nature of Venus, some of iron, and one of gold, of pure angel-gold, of the bigness of a thirty-three shilling piece of King James's coin. In the circumference on one side was engraven, *Vicit Leo de tribu Judæ Tetragrammaton* [symbol: cross], within the middle there was engraven a holy lamb. In the other circumference there was Amraphel and three [symbol: cross]. In the middle, *Sanctus Petrus*, *Alpha* and *Omega*.

{33}

The occasion of framing this sigil was thus; her former husband travelling into Sussex, happened to lodge in an inn, and to lie in a chamber thereof; wherein, not many months before, a country grazier had lain, and in the night cut his own throat; after this night's lodging, he was perpetually, and for many years, followed by a spirit, which vocally and articulately provoked him to cut his throat: he was used frequently to say, 'I defy thee, I defy thee,' and to spit at the spirit; this spirit followed him many years, he not making any body acquainted with it; at last he grew melancholy and discontented; which being carefully observed by his wife, she many times hearing him pronounce, 'I defy thee,' &c. she desired him to acquaint her with the cause of his distemper, which he then did. Away she went to Dr. Simon Forman, who lived then in Lambeth, and {34}acquaints him with it; who having framed this sigil, and hanged it about his neck, he wearing it continually until he died, was never more molested by the spirit: I

sold the sigil for thirty-two shillings, but transcribed the words *verbatim* as I have related. Sir, you shall now have a story of this Simon Forman, as his widow, whom I well knew, related it unto me. But before I relate his death, I shall acquaint you something of the man, as I have gathered them from some manuscripts of his own writing.

OF DR. SIMON FORMAN

He was a chandler's son in the city of Westminster. He travelled into Holland for a month, in 1580, purposely to be instructed in astrology, and other more occult sciences; as also in physick, taking his degree of Doctor beyond seas: being sufficiently furnished {35}and instructed with what he desired, he returned into England, towards the latter end of the reign of Queen Elizabeth, and flourished until that year of King James, wherein the Countess of Essex, the Earl of Somerset, and Sir Thomas Overbury's matters were questioned. He lived in Lambeth, with a very good report of the neighbourhood, especially of the poor, unto whom he was very charitable. He was a person that in horary questions (especially thefts) was very judicious and fortunate; so also in sicknesses, which indeed was his master-piece. In resolving questions about marriage he had good success: in other questions very moderate. He was a person of indefatigable pains. I have seen sometimes half one sheet of paper wrote of his judgment upon one question; in writing whereof he used much tautology, as you may see yourself, (most excellent Esquire) {36}if you read a great book of Dr. Flood's, which you have, who had all that book from the manuscripts of Forman; for I have seen the same word for word in an English manuscript formerly belonging to Doctor Willoughby of Gloucestershire. Had Forman lived to have methodized his own papers, I doubt not but he would have advanced the Jatro-mathematical part thereof very completely; for he was very observant, and kept notes of the success of his judgments, as in many of his

figures I have observed. I very well remember to have read, in one of his manuscripts, what followeth.

'Being in bed one morning,' (says he) 'I was desirous to know whether I should ever be a Lord, Earl, or Knight, &c. whereupon I set a figure; and thereupon my judgment:' by which he concluded, that within two years time he should be a Lord or great man: {37}'But,' says he, 'before the two years were expired, the Doctors put me in Newgate, and nothing came.' Not long after, he was desirous to know the same things concerning his honour or greatship. Another figure was set, and that promised him to be a great Lord within one year. But he sets down, that in that year he had no preferment at all; only 'I became acquainted with a merchant's wife, by whom I got well.' There is another figure concerning one Sir —— Ayre his going into Turkey, whether it would be a good voyage or not: the Doctor repeats all his astrological reasons and musters them together, and then gave his judgment it would be a fortunate voyage. But under this figure he concludes, 'this proved not so, for he was taken prisoner by pirates ere he arrived in Turkey, and lost all.' He set several questions to know if he should attain the philosophers' {38}stone, and the figures, according to his straining, did seem to signify as much; and then he tuggs upon the aspects and configurations, and elected a fit time to begin his operation; but, by and by, in conclusion, he adds, 'so the work went very forward; but upon the [symbol: aspect "squares"] of [symbol: aspect "conjunctions"] the setting-glass broke, and I lost all my pains:' he sets down five or six such judgments, but still complains all came to nothing, upon the malignant aspects of [symbol: Saturn] and [symbol: Mars]. Although some of his astrological judgments did fail, more particularly those concerning himself, he being no way capable of such preferment as he ambitiously desired; yet I shall repeat some other of his judgments, which did not fail, being performed by conference with spirits. My mistress went once unto him, to know when her husband, then in Cumberland, would return, he having promised to be at home {39}near the time of the question; after some consideration, he told her to this

effect: 'Margery,' for so her name was, 'thy husband will not be at home these eighteen days; his kindred have vexed him, and he is come away from them in much anger: he is now in Carlisle, and hath but three-pence in his purse.' And when he came home he confessed all to be true, and that upon leaving his kindred he had but three-pence in his purse. I shall relate one story more, and then his death.

One Coleman, clerk to Sir Thomas Beaumont of Leicestershire, having had some liberal favours both from his lady and her daughters, bragged of it, &c. The Knight brought him into the star-chamber, had his servant sentenced to be pilloried, whipped, and afterwards, during life, to be imprisoned. The sentence was executed in London, and was {40}to be in Leicestershire: two keepers were to convey Coleman from the Fleet to Leicester. My mistress taking consideration of Coleman, and the miseries he was to suffer, went presently to Forman, acquainted him therewith; who, after consideration, swore Coleman had lain both with mother and daughters; and besides said, that the old Lady being afflicted with fits of the mother, called him into her chamber to hold down the fits with his hands; and that he holding his hands about the breast, she cried 'Lower, lower,' and put his hands below her belly; and then—He also told my mistress in what posture he lay with the young ladies, &c. and said, 'they intend in Leicester to whip him to death; but I assure thee, Margery, he shall never come there; yet they set forward to-morrow,' says he; and so his two keepers did, Coleman's legs being locked {41}with an iron chain under the horse's belly. In this nature they travelled the first and second day; on the third day the two keepers, seeing their prisoner's civility the two preceding days, did not lock his chain under the horse's belly as formerly, but locked it only to one side. In this posture they rode some miles beyond Northampton, when on a sudden, one of the keepers had a necessity to untruss, and so the other and Coleman stood still; by and by the other keeper desired Coleman to hold his horse, for he had occasion also: Coleman immediately took one of their swords, and ran through two of the horses, killing them stark dead; gets upon the other, with one of their swords; 'Farewell,

gentlemen,' quoth he, 'tell my master I have no mind to be whipped in Leicestershire,' and so went his way. The two keepers in all haste went to a gentleman's {42}house near at hand, complaining of their misfortune, and desired of him to pursue their prisoner, which he with much civility granted; but ere the horses could be got ready, the mistress of the house came down, and enquiring what the matter was, went to the stable, and commanded the horses to be unsaddled, with this sharp speech—'Let the Lady Beaumont and her daughters live honestly, none of my horses shall go forth upon this occasion.'

I could relate many such stories of his performances; as also what he wrote in a book left behind him, *viz.* 'This I made the devil write with his own hand in Lambeth Fields 1596, in June or July, as I now remember.' He professed to his wife there would be much trouble about Carr and the Countess of Essex, who frequently resorted unto him, and from whose company he would sometimes {43}lock himself in his study a whole day. Now we come to his death, which happened as follows: the Sunday night before he died, his wife and he being at supper in their garden-house, she being pleasant, told him, that she had been informed he could resolve, whether man or wife should die first; 'Whether shall I' (quoth she) 'bury you or no?' 'Oh Trunco,' for so he called her, 'thou wilt bury me, but thou wilt much repent it.' 'Yea, but how long first?' 'I shall die,' said he, 'ere Thursday night.' Monday came, all was well. Tuesday came, he not sick. Wednesday came, and still he was well; with which his impertinent wife did much twit him in his teeth. Thursday came, and dinner was ended, he very well: he went down to the water-side, and took a pair of oars to go to some buildings he was in hand with in Puddle-dock. Being in the middle {44}of the Thames, he presently fell down, only saying, 'An impost, an impost,' and so died. A most sad storm of wind immediately following. He died worth one thousand two hundred pounds, and left only one son called Clement. All his rarities, secret manuscripts, of what quality soever, Dr. Napper of Lindford in Buckinghamshire had, who had been a long time his scholar; and of

whom Forman was used to say he would be a dunce: yet in continuance of time he proved a singular astrologer and physician. Sir Richard now living, I believe, has all those rarities in possession, which were Forman's, being kinsman and heir unto Dr. Napper. (His son Thomas Napper, Esq.; most generously gave most of these manuscripts to Elias Ashmole, Esq.;) I hope you will pardon this digression.

After my mistress was dead, I lived most {45}comfortably, my master having a great affection for me.

The year 1625 now comes on, and the plague exceeding violent, I will relate what I observed the spring before it broke forth. Against our corner house every night there would come down, about five or six of the clock, sometime one hundred or more boys, some playing, others as if in serious discourse, and just as it grew dark would all be gone home; many succeeding years there was no such, or any concourse, usually no more than four or five in a company: In the spring of 1625, the boys and youths of several parishes in like number appeared again, which I beholding, called Thomas Sanders, my landlord, and told him, that the youth and young boys of several parishes did in that nature assemble and play, in the beginning of the year 1625. 'God bless us,' quoth {46}I, 'from a plague this year;' but then there succeeded one, and the greatest that ever was in London. In 1625, the visitation encreasing, and my master having a great charge of money and plate, some of his own, some other men's, left me and a fellow-servant to keep the house, and himself in June went into Leicestershire. He was in that year feoffee collector for twelve poor alms-people living in Clement-Dane's Church-Yard; whose pensions I in his absence paid weekly, to his and the parish's great satisfaction. My master was no sooner gone down, but I bought a bass-viol, and got a master to instruct me; the intervals of time I spent in bowling in Lincoln's-Inn-Fields, with Wat the cobler, Dick the blacksmith, and such like companions: We have sometimes been at our work at six in the morning, and so continued till three or four in

the afternoon, {47}many times without bread or drink all that while. Sometimes I went to church and heard funeral sermons, of which there was then great plenty. At other times I went early to St. Antholine's in London, where there was every morning a sermon. The most able people of the whole city and suburbs were out of town; if any remained, it were such as were engaged by parish-officers to remain; no habit of a gentleman or woman continued; the woeful calamity of that year was grievous, people dying in the open fields and in open streets. At last, in August, the bills of mortality so encreased, that very few people had thoughts of surviving the contagion: the Sunday before the great bill came forth, which was of five thousand and odd hundreds, there was appointed a sacrament at Clement Dane's; during the destributing whereof I do very {48}well remember we sang thirteen parts of the one hundred and nineteenth Psalm. One Jacob, our minister (for we had three that day, the communion was so great) fell sick as he was giving the sacrament, went home, and was buried of the plague the Thursday following, Mr. James, another of the ministers, fell sick ere he had quite finished, had the plague, and was thirteen weeks ere he recovered. Mr. Whitacre, the last of the three, escaped not only then, but all the contagion following, without any sickness at all; though he officiated at every funeral, and buried all manner of people, whether they died of the plague or not. He was given to drink, seldom could preach more than one quarter of an hour at a time, &c. In November my master came home. My fellow-servant's and my diet came weekly to six shillings and sixpence, sometimes {49}to seven shillings, so cheap was diet at that time.

In February of that year, my master married again (one who after his death became my wife.) In the same year he settled upon me, during my life, twenty pounds per annum, which I have enjoyed ever since, even to the writing hereof.

May 22, 1627, my master died at the corner house in the Strand, where I also lived so long. He died intestate; my mistress relinquishing the administration, it came to his

elder brother, who assigned the estate over to me for payment of my master's debts; which being paid, I faithfully returned the remaining part unto his administrator; nor had one penny of the estate more than twenty pounds per annum, which was allowed me by contract, to undertake the payment of my master's debts.

{50}

OF MY MARRIAGE THE FIRST TIME.

My mistress, who had been twice married to old men, was now resolved to be couzened no more; she was of a brown ruddy complexion, corpulent, of but mean stature, plain, no education, yet a very provident person, and of good condition: she had many suitors, old men, whom she declined; some gentlemen of decayed fortunes, whom she liked not, for she was covetous and sparing: by my fellow-servant she was observed frequently to say, she cared not if she married a man that would love her, so that he had never a penny; and would ordinarily talk of me when she was in bed: this servant gave me encouragement to give the onset: I was much perplexed hereat, for should I attempt her, and be slighted, {51}she would never care for me afterwards; but again, I considered that if I should attempt and fail, she would never speak of it; or would any believe I durst be so audacious as to propound such a question, the disproportion of years and fortune being so great betwixt us: however, all her talk was of husbands, and in my presence saying one day after dinner, she respected not wealth, but desired an honest man; I made answer, I thought I could fit her with such a husband; she asked me, where? I made no more ado, but presently saluted her, and told her myself was the man: she replied, I was too young; I said nay; what I had not in wealth, I would supply in love; and saluted her frequently, which she accepted lovingly; and next day at dinner made me sit down at dinner with my hat on my head, and said, she intended to make me her husband; {52}for which I gave her many salutes, &c.

I was very careful to keep all things secret, for I well knew, if she should take counsel of any friend, my hopes would be frustrated, therefore I suddenly procured her consent to marry, unto which she assented; so that upon the eighth day of September, 1627, at St. George's church in Southwark, I was married unto her, and for two whole years we kept it secret. When it was divulged, and some people blamed her for it, she constantly replied, that she had no kindred; if I proved kind, and a good husband, she would make me a man; if I proved otherwise, she only undid herself. In the third and fourth years after our marriage, we had strong suits of law with her first husband's kindred, but overthrew them in the end. During all the time of her life, which was {53}until October, 1633, we lived very lovingly, I frequenting no company at all; my exercises were sometimes angling, in which I ever delighted: my companions, two aged men. I then frequented lectures, two or three in a week; I heard Mr. Sute in Lombard-Street, Mr. Gouge of Black-Fryars, Dr. Micklethwait of the Temple, Dr. Oldsworth, with others, the most learned men of these times, and leaned in judgment to Puritanism. In October, 1627, I was made free of the Salters' company in London.

HOW I CAME TO STUDY ASTROLOGY.

It happened on one Sunday, 1632, as myself and a Justice of Peace's clerk were, before service, discoursing of many things, he chanced to say, that such a person was a great scholar, nay, so learned, that his could {54}make an Almanack, which to me then was strange: one speech begot another, till, at last, he said, he could bring me acquainted with one Evans in Gunpowder-Alley, who had formerly lived in Staffordshire, that was an excellent wise man, and studied the Black Art. The same week after we went to see Mr. Evans. When we came to his house, he, having been drunk the night before, was upon his bed, if it be lawful to call that a bed whereon he then lay; he roused up himself, and, after some compliments, he was content to instruct me in astrology; I attended his best opportunities for seven or eight weeks, in which time I could set a figure perfectly:

books he had not any, except *Haly de judiciis Astrorum*, and *Orriganus's Ephemerides*; so that as often as I entered his house, I thought I was in the wilderness. Now something of the man: he {55}was by birth a Welshman, a Master of Arts, and in sacred orders; he had formerly had a cure of souls in Staffordshire, but now was come to try his fortunes at London, being in a manner enforced to fly for some offences very scandalous, committed by him in these parts, where he had lately lived; for he gave judgment upon things lost, the only shame of astrology: he was the most saturnine person my eyes ever beheld, either before I practised or since; of a middle stature; broad forehead, beetle-browed, thick shoulders, flat nosed, full lips, down-looked, black curling stiff hair, splay-footed; to give him his right, he had the most piercing judgment naturally upon a figure of theft, and many other questions, that I ever met withal; yet for money he would willingly give contrary judgments, was much addicted to debauchery, and then very abusive and quarrelsome, {56}seldom without a black eye, or one mischief of other: this is the same Evans who made so many antimornal cups, upon the sale whereof he principally subsisted; he understood Latin very well, the Greek tongue not at all: he had some arts above, and beyond astrology, for he was well versed in the nature of spirits, and had many times used the circular way of invocating, as in the time of our familiarity he told me. Two of his actions I will relate, as to me delivered. There was in Staffordshire a young gentlewoman that had, for her preferment, married an aged rich person, who was desirous to purchase some lands for his wife's maintenance; but this young gentlewoman, his wife, was desired to buy the land in the name of a gentleman, her very dear friend, but for her use: after the aged man was dead, the widow could by no means procure {57}the deed of purchase from her friend; whereupon she applies herself to Evans, who, for a sum of money, promises to have her deed safely delivered into her own hands; the sum was forty pounds. Evans applies himself to the invocation of the angel Salmon, of the nature of Mars, reads his Litany in the *Common-Prayer-Book* every day, at select hours, wears his surplice, lives orderly all that time; at the fortnight's end Salmon appeared, and having received his commands what to do, in a

small time returns with the very deed desired, lays it down gently upon a table where a white cloth was spread, and then, being dismissed, vanished. The deed was, by the gentleman who formerly kept it, placed among many other of his evidences in a large wooden chest, and in a chamber at one end of the house; but upon Salmon's; removing and bringing away the {58}deed, all that bay of building was quite blown down, and all his own proper evidences torn all to pieces. The second story followeth.

Some time before I became acquainted with him, he then living in the Minories, was desired by the Lord Bothwell and Sir Kenelm Digby to show them a spirit. He promised so to do: the time came, and they were all in the body of the circle, when lo, upon a sudden, after some time of invocation, Evans was taken from out the room, and carried into the field near Battersea Causeway, close to the Thames. Next morning a countryman going by to his labour, and espying a man in black cloaths, came unto him and awaked him, and asked him how he came there? Evans by this understood his condition, enquired where he was, how far from London, and in what parish he was; which when he understood, he told the labourer he had been {59}late at Battersea the night before, and by chance was left there by his friends. Sir Kenelm Digby and the Lord Bothwell went home without any harm, and came next day to hear what was become of him; just as they, in the afternoon, came into the house, a messenger came from Evans to his wife, to come to him at Battersea. I enquired upon what account the spirit carried him away: who said, he had not, at the time of invocation, made any suffumigation, at which the spirits were vexed. It happened, that after I discerned what astrology was, I went weekly into Little Britain, and bought many books of astrology, not acquainting Evans therewith. Mr. A. Bedwell, Minister of Tottenham-High-Cross near London, who had been many years chaplain to Sir Henry Wotton, whilst he was Ambassador at Venice, and assisted Pietro Soave Polano, in composing {60}and writing the Council of Trent, was lately dead; and his library being sold into Little Britain, I bought amongst them my choicest books of astrology. The occasion of our falling out

was thus: a woman demanded the resolution of a question, which when he had done, she went her way; I standing by all the while, and observing the figure, asked him why he gave the judgment he did, since the signification shewed quite the contrary, and gave him my reasons; which when he had pondered, he called me boy, and must he be contradicted by such a novice! But when his heat was over, he said, had he not so judged to please the woman, she would have given him nothing, and he had a wife and family to provide for; upon this we never came together after. Being now very meanly introduced, I applied myself to study those books I had obtained, many times twelve, or {61}fifteen, or eighteen hours day and night; I was curious to discover, whether there was any verity in the art or not. Astrology in this time, viz. in 1633, was very rare in London, few professing it that understood any thing thereof. Let it not repent you (O noble Esquire) if now I make a short digression of such persons as then professed astrology, that posterity may understand in what condition I found it, and in whose hands that little that remained was lodged.

There lived then in Houndsditch one Alexander Hart, who had been a soldier formerly, a comely old man, of good aspect; he professed questionary astrology, and a little of physick; his greatest skill was to elect young gentlemen fit times to play at dice, that they might win or get money. I went unto him for resolutions for three questions at several times, and he erred in every one. {62}To speak soberly of him, he was but a cheat, as appeared suddenly after; for a rustical fellow of the city, desirous of knowledge, contracted with Hart to assist for a conference with a spirit, and paid him twenty pounds of thirty pounds the contract. At last, after many delays, and no spirit appearing, or money returned, the young man indicts him for a cheat at the Old Bailey in London; the Jury found the bill, and at the hearing of the cause this jest happened: some of the bench enquired what Hart did? 'He sat like an Alderman in his gown,' quoth the fellow; at which the court fell into a great laughter, most of the court being Aldermen. He was to have been set upon the pillory for this cheat; but John Taylour,

the Water Poet, being his great friend, got the Lord Chief Justice Richardson to bail him, ere he stood upon the pillory, and so Hart fled presently {63}into Holland, where he ended his days. It was my fortune, upon the sale of his books in 1634, to buy *Argoll's Primum Mobile* for fourteen shillings, which I only wanted.

In Lambeth Marsh at the same time lived one Captain Bubb, who resolved horary questions astrologically; a proper handsome man, well spoken, but withal covetous, and of no honesty, as will appear by this story, for which he stood upon the pillory. A certain butcher was robbed, going to a fair, of forty pounds; he goes to Bubb, who for ten pounds in hand paid, would help him to the thief; appoints the butcher such a night precisely, to watch at such a place, and the thief should come thither; commanded him by any means to stop him; the butcher attends according to direction. About twelve in the night there comes one riding very fiercely upon a full gallop, whom the butcher knocks {64}down, and seized both upon man and horse: the butcher brings the man and horse to the next town, but then the person whom the butcher attacked was John the servant of Dr. Bubb; for which the Captain was indicted and suffered upon the pillory, and afterwards ended his days in great disgrace.

There was also one Jeffry Neve, at this time a student in physic and astrology; he had formerly been a merchant in Yarmouth, and Mayor of the town, but failing in estate, went into the Low-Countries, and at Franecker took the degree, of doctor in Physick; he had some little smattering in astrology; could resolve a question of theft, or love-question, something of sickness; a very grave person, laborious and honest, of tall stature and comely feature; he died of late years, almost in the very street near Tower-Hill: he had a design of printing two hundred {65}verified questions, and desired my approbation ere they went to press; that I first would see them, and then give testimony. When I had perused the first forty, I corrected thirty of them, would read over no more: I showed him how erroneous they were, desired his emendation of the rest, which he

performed not. These were afterwards, in R. Saunders's custody, bought by him either of his son or of a stationer.[2]

Footnote 2:(return)

But first offered to be sold to me for twenty shillings. When Mr. Saunders died I bought them of his son for less. E. A——.

There was then William Poole, a nibbler at astrology, sometimes a gardener, an apparitor, a drawer of linen; as quoifs, handkerchiefs; a plaisterer and a bricklayer; he would brag many times he had been of seventeen professions; was very good company for drolling, as you yourself very well remember {66}(most honoured Sir);[3] he pretended to poetry; and that posterity may have a taste of it, you shall have here inserted two verses of his own making; the occasion of making them was thus. One Sir Thomas Jay, a Justice of the Peace in Rosemary-Lane, issued out his warrant for the apprehension of Poole, upon a pretended suggestion, that he was in company with some lewd people in a tavern, where a silver cup was lost, *Anglice* stolen. Poole, hearing of the warrant, packs up his little trunk of books, being all his library, and runs to Westminster; but hearing some months after that the Justice was dead and buried, he came and enquired where the grave was; and after the discharge of his belly upon the grave, left {67}these two verses upon it, which he swore he made himself.

Here lieth buried Sir Thomas Jay, Knight,
Who being dead, I upon his grave did shite.

Footnote 3:(return)

December 17, this William Poole was married to Alice How, at St. George's Church in Southwark. Mr. Lilly gave her to him.

He died about 1651, or 1652, at St. Mary Overy's in Southwark; and this was part of his last will.

'Item; I give to Dr. Ardee all my books, and one manuscript of my own, worth one hundred of Lilly's Introduction.'

'Item; If Dr. Ardee give my wife any thing that is mine, I wish the devil may fetch him body and soul.' The Doctor, terrified with this curse, gave me all the books and his goods which I presently gave to his widow.—-*Interdum seria jocis*.

Now also lived this Dr. Ardee, but his true name was Richard Delahay, formerly an Attorney; he studied astrology and physick, being in necessity, and forced from Derbyshire, {68}where he had lived, by the old Countess of Shrewsbury; he was of moderate judgment, both in astrology and physick. He had formerly been well acquainted with Charles Sledd,[4] an apothecary, who used the crystal, and had a very perfect sight. This Dr. Ardee hath many times affirmed unto me, (*esto fides*) that an angel, one time, appeared unto him, and offered him a lease of his life for one thousand years; he died about the age of fourscore years; left his widow, who married into Kent,[5] worth two or three thousand pounds, and William Poole's estate came to four or five pounds.

Footnote 4:(return)

Of this Charles Sledd, there is mention made in Dr. Dee's book of his discourse with spirits, set forth by Dr. Casaubon.

Footnote 5:(return)

To one Moreland.

In the years 1632 and 1633, John Booker became famous for a prediction of his upon a {69}solar eclipse in the 19th degree of Aries 1663, taken out of *Leovitius de magnis conjunctionibus*, viz. *Oh Reges et Principes &c.* Both the King of Bohemia, and Gustavus King of Sweden, dying during the effects of that eclipse.

John Booker was born in Manchester, of good parentage, in the year 1601; was in his youth well instructed in the Latin tongue, which he understood very well. He seemed from his infancy to be designed for astrology; for from the time he had any understanding, he would be always poring on, and studying almanacks. He came to London at fitting years, and served an apprenticeship to an haberdasher in Laurence-Lane, London; but either wanting stock to setup, or disliking the calling, he left his trade, and taught to write at Hadley in Middlesex several scholars in that school: he wrote singularly well both {70}Secretary and Roman. In process of time he served Sir Christopher Clethero, Knight, Alderman of London, as his clerk, being a city Justice of Peace: he also was clerk to Sir Hugh Hammersley, Alderman of London, both which he served with great credit and estimation; and by that means became not only well known, but as well respected of the most eminent citizens of London, even to his dying day.

He was an excellent proficient in astrology, whose excellent verses upon the twelve months, framed according to the configurations of each month, being blessed with success according to his predictions, procured him much reputation all over England: he was a very honest man, abhorred any deceit in the art he studied; had a curious fancy in judging of thefts, and as successful in resolving love-questions: he was no mean proficient {71}in astronomy; he understood much of physick; was a great admirer of the antimonial cup; not unlearned in chymistry, which he loved well, but did not practise. He was inclined to a diabetes; and in the last three years of his life was afflicted with a dysentery, which at last consumed him to nothing: he died of good fame in 1667. Since his decease I have seen one nativity of his performance exactly directed, and judged with as much learning as from astrology can be expected.

His library of books came short of the world's approbation, and were by his widow sold to Elias Ashmole, Esq. who most generously gave her[6] far more money than they were

worth; but out of his respects unto the deceased and his memory, he most willingly {72}paid her the money. He left behind him two sons and two daughters. He left in writing very little but his annual prognostications. He began first to write about the year 1630; he wrote *Bellum Hibernicale*, in the time of the long parliament, a very sober and judicious book: the epistle thereunto I gave him. He wrote lately a small treatise of Easter-Day, a very learned thing, wherein he shewed much learning and reading. To say no more of him, he lived an honest man, his fame not questioned at his death.

Footnote 6:(return)

They cost me one hundred and forty pounds.

In this year 1633, I became acquainted with Nicholas Fiske, licentiate in physick, who was born in Suffolk, near Framingham[7] Castle, of very good parentage, who educated him at country schools, until he was fit for the university; but he went not to the {73}academy, studying at home both astrology and physick, which he afterwards practised in Colchester; and there was well acquainted with Dr. Gilbert, who wrote *De Magnete*. He came afterwards unto London, and exercised his faculty in several places thereof. (For in his youth he would never stay long in one house.) In 1633 he was sent for out of Suffolk by Dr. Winston of Gresham College, to instruct the Lord Treasurer Weston's son in arithmetick, astronomy upon the globes, and their uses. He was a person very studious, laborious, of good apprehension, and had by his own industry obtained both in astrology, physick, arithmetick, astronomy, geometry and algebra, singular judgment: he would in astrology resolve horary questions very soundly; but was ever diffident of his own abilities: he was exquisitely skilful in the art of directions upon {74}nativities, and had a good genius in performing judgment thereupon, but very unhappy he was, that he had no genius in teaching his scholars, for he never perfected any: his own son Matthew hath often told me, that where his father did teach any

zain.adwan

scholars in his time, they would principally learn of him; he had Scorpio ascending, and was secretly envious to those he thought had more parts than himself; however, I must be ingenuous, and do affirm, that by frequent conversation with him, I came to know which were the best authors, and much to enlarge my judgment, especially in the art of directions: he visited me most days once after I became acquainted with him, and would communicate his most doubtful questions unto me, and accept of my judgment therein rather than his own: he singularly well judged and directed Sir Robert Holborn's {75}nativity, but desired me to adjudge the first house, seventh and tenth thereof, which I did, and which nativity (since Sir Robert gave it me) came to your hands, and remains in your library; [oh learned Esquire!] he died about the seventy-eighth year of his age, poor.

Footnote 7:(return)

There is no such place in Suffolk, it being mistaken for Framlingham in that county.

In this year also William Bredon, parson or vicar of Thornton in Buckinghamshire, was living, a profound divine, but absolutely the most polite person for nativities in that age, strictly adhering to Ptolemy, which he well understood; he had a hand in composing Sir Christopher Heydon's *Defence of Judicial Astrology*, being that time his chaplain; he was so given over to tobacco and drink, that when he had no tobacco, he would cut the bell-ropes and smoke them.

I come now to continue the story of my own life, but thought it not inconvenient to {76}commit unto memory something concerning those persons who practised when first I became a student in astrology; I have wrote nothing concerning any of them, which I myself do not either know, or believe to be true.

In October 1633 my first wife died, and left me whatever was hers: it was considerable, very near to the value of one thousand pounds.

One whole year and more I continued a widower, and followed my studies very hard; during which time a scholar pawned unto me, for forty shillings, *Ars Notoria*,[8] a large volume wrote in parchment, with the names of those angels, and their pictures, which are thought and believed by wise men, to teach and instruct in all the several {77}liberal sciences, and is attained by observing elected times, and those prayers appropriated unto the several angels.

Footnote 8:(return)

Among Dr. Napier's MSS. I had an *Ars Notoria*, written by S. Forman in large vellum.

I do ingenuously acknowledge, I used those prayers according to the form and direction prescribed for some weeks, using the word *astrologia* for *astronomia*; but of this no more: that *Ars Notoria*, inserted in the latter end of Cornelius Agrippa signifieth nothing; many of the prayers being not the same, nor is the direction to these prayers any thing considerable.

In the year 1634, I taught Sir George Peckham, Knight, astrology, that part which concerns sickness, wherein he so profited, that in two or three months he would give a very true discovery of any disease, only by his figures. He practised in Nottingham, but unfortunately died in 1635, at St. Winifred's Well in Wales; in which well he continued {78}so long mumbling his *Pater Nosters* and *Sancta Winifrida ora pro me*, that the cold struck into his body; and, after his coming forth of that well, never spoke more.

In this year 1634, I purchased the moiety of thirteen houses in the Strand for five hundred and thirty pounds.

In November, the 18th day, I was again the second time married, and had five hundred pounds portion with that wife; she was of the nature of Mars.

Two accidents happened to me in that year something memorable.

Davy Ramsey, his Majesty's clock-maker, had been informed, that there was a great quantity of treasure buried in the cloyster of Westminster-Abbey; he acquaints Dean Williams therewith, who was also then Bishop of Lincoln; the Dean gave him liberty to search after it, with this proviso, that if {79}any was discovered, his church should have a share of it. Davy Ramsey finds out one John Scott,[9] who pretended the use of the Mosaical rods, to assist him herein: I was desired to join with him, unto which I consented. One winter's night, Davy Ramsey, with several gentlemen, myself, and Scott, entered the cloysters; we played the hazel-rod round about the cloyster; upon the west-side of the cloysters the rods turned one over another, an argument that the treasure was there. The labourers digged at least six foot deep, and then we met with a coffin; but in regard it was not heavy, we did not open, which we afterwards much repented. From the cloysters we went into the Abbey church, where, upon a sudden, (there being no wind when we began) so fierce, so high, so blustering {80}and loud a wind did rise, that we verily believed the west-end of the church would have fallen upon us; our rods would not move at all; the candles and torches, all but one, were extinguished, or burned very dimly.[10] John Scott, my partner, was amazed, looked pale, knew not what to think or do, until I gave directions and command to dismiss the dæmons; which when done, all was quiet again, and each man returned unto his lodging late, about twelve o'clock at night; I could never since be induced to join with any in such-like actions.

Footnote 9:(return)

This Scott lived in Pudding-Lane, and had some time been a page (or such like) to the Lord Norris.

Footnote 10:(return)

Davy Ramsey brought an half quartern sack to put the treasure in.

The true miscarriage of the business, was by reason of so many people being present at the operation; for there was about thirty, some laughing, others deriding us; so that if we had not dismissed the dæmons, I believe {81}most part of the Abbey church had been blown down; secrecy and intelligent operators, with a strong confidence and knowledge of what they are doing, are best for this work.

In 1634, or 1635, a Lady living in Greenwich, who had tried all the known artists in London, but to no purpose, came weeping and lamenting her condition, which was this: she had permitted a young Lord to have the use of her body, till she was with child by him; after which time he could not or would not endure her sight, but commanded his lacquies and servants to keep his doors fast shut, lest she should get into his chamber; or if they chanced to see her near his lodging, to drive her away, which they several times had done. Her desire unto me was to assist her to see him, and then she should be content; whereupon I ordered, such {82}a day, such an hour of that day, to try her fortune once more. She obeyed; and when she came to the King's Bench, where the Lord there was imprisoned, the outward door stood wide open: none speaking a word unto her, she went up stairs, no body molesting her; she found the Lord's chamber door wide open: he in bed, not a servant to be heard or seen, so she was pleased. Three days after she came to acquaint me with her success, and then drew out of her pocket a paper full of ratsbane, which, had she not had admission unto him that day I appointed, she would in a pint of white wine have drank at the stair's foot where the Lord lodged. The like misfortune befell her after that; when the Lord was out of prison: then I ordered her such a day to go and see a play at Salisbury-Court; which she did, and within one quarter of an hour {83}the Lord came into the same box wherein she was. But I grew weary of such employments, and since have burned my books which instructed these curiosities: for after that I became melancholy, very much afflicted with the hypochondriack, growing lean and spare, and every day worse; so that in the year 1635 my infirmity continuing, and my acquaintance increasing, I resolved to live in the country, and in

March and April 1636 removed my goods unto Hersham, where I now live; and in May my person, where I continued until 1641, no notice being taken who, or what I was.

In the years 1637 and 1638, I had great lawsuits both in the Exchequer and Chancery, about a lease I had of the annual value of eighty pounds: I got the victory.

In the year 1640 I instructed John Humphreys, master of that art, in the study of {84}astrology: upon this occasion, being at London, by accident in Fleet-Street, I met Dr. Percival Willoughby of Derby; we were of old acquaintance, and he but by great chance lately come to town, we went to the Mitre-Tavern in Fleet-Street, where I sent for old Will Poole the astrologer, living then in Ram-Alley: being come to us, the Doctor produced a bill, set forth by a master of arts in Cambridge, intimating his abilities for resolving of all manner of questions astrologically. The bill was shewed, and I wondering at it Poole made answer, he knew the man, and that he was a silly fool; 'I,' quoth he, 'can do more than he; he sees me every day, he will be here by and by;' and indeed he came into our room presently: Poole had, just as we came to him, set a figure, and then shewed it me, desiring my judgement; which I refused, but desired the master of arts to {85}judge first; he denied, so I gave mine, to the very great liking of Humphreys, who presently enquired, if I would teach him, and for what? I told him I was willing to teach, but would have one hundred pounds. I heard Poole, whilst I was judging the figure, whisper in-Humphrey's ear, and swear I was the best in England. Staying three or four days in town, at last we contracted for forty pounds, for I could never be quiet from his solicitations; he invited me to supper, and before I had shewed him any thing, paid me thirty-five pounds. As we were at supper a client came to speak with him, and so up into his closet he went with his client; I called him in before he set his figure, or resolved the question, and instantly acquainted him how he should discover the moles or marks of his client: he set his figure, and presently discovers four moles the querent {86}had; and was so overjoyed therewith, that he came tumbling

down the stairs, crying, 'Four by G——, four by G——, I will not take one hundred pounds for this one rule.' In six weeks time, and tarrying with him three days in a week, he became a most judicious person.

This Humphreys was a laborious person, vain-glorious, loquacious, fool-hardy, desirous of all secrets which he knew not, insomuch that he would have given me two hundred pounds to have instructed him in some curiosities he was persuaded I had knowledge of, but, *Artis est celare artem*, especially to those who live not in the fear of God, or can be masters of their own counsels: he was in person and condition such another as that monster of ingratitude my *quondam* taylor, John Gadbury. After my refusal of teaching him, what he was not capable of, we grew strange, though I afforded him many civilities {87}whenever he required it; for after the siege of Colchester he wrote a book against me, called *Anti Merlinus-Anglicus*, married a second wife, his first living in Cambridgeshire, then practised physick by a contrary name, having intentions to practise in Ireland; he went to Bristol, but there understanding the parliament's forces had reduced that kingdom, he came back to London, but durst not abide therein; but turning from his second wife, who also had another husband, he went to sea, with intention for Barbadoes, but died by the way in his voyage. I had never seen John Booker at that time; and telling him one day I had a desire to see him, but first, ere I would speak with him, I would fit myself with my old rules, and rub up my astrology; for at that time (and this was 1640) I thought John Booker the greatest and most complete astrologer in the world. My scholar {88}Humphreys presently made answer, 'Tutor, you need not pump for any of your former knowledge, John Booker is no such pumper; we met,' saith he, 'the other day, and I was too hard for him myself, upon judgment of three or four questions.' If all the transactions happening unto that my scholar were in one volume, they would transcend either *Guzman*, *Don Quixote*, *Lazarillo de Tormes*, or any other of the like nature I ever did see.

Having now in part recovered my health, being weary of the country, and perceiving there was money to be got in London, and thinking myself to be as sufficiently enabled in astrology as any I could meet with, I made it my business to repair thither; and so in September 1641 I did; where, in the years 1642 and 1643, I had great leisure to better my former knowledge: I then read over all {89}my books of astrology, over and over; had very little or no practice at all: and whereas formerly I could never endure to read *Valentine Naibod's Commentary upon Alcabitius*, now having seriously studied him, I found him to be the profoundest author I ever met with; him I traversed over day and night, from whom I must acknowledge to have advanced my judgment and knowledge unto that height I soon after arrived at, or unto: a most rational author, and the sharpest expositor of *Ptolemy* that hath yet appeared. To exercise my genius, I began to collect notes, and thought of writing some little thing upon the [symbol: aspect "conjunction"] of [symbol: Saturn] and [symbol: Jupiter] then approaching: I had not wrote above one sheet, and that very meanly, but James Lord Galloway came to see me; and, by chance, casting his eyes upon that rude collection, he read it over, and so approved {90}of it, yea, so encouraged me to proceed farther, that then, and after that time, I spent most of my time in composing thereof, and bringing it, in the end, into that method wherein it was printed 1644. I do seriously now profess, I had not the assistance of any person living, in the writing or composing thereof. Mr. Fiske sent me a small manuscript, which had been Sir Christopher Heydon's, who had wrote something of the conjunction of [symbol: Saturn] and [symbol: Jupiter], 1603; out of which, to bring my method in order, I transcribed, in the beginning, five or six lines, and not any more, though that graceless fellow Gadbury wrote the contrary: but, *Semel et semper nebulo et mendax*. I did formerly write one treatise, in the year 1639, upon the eclipse of the sun, in the eleventh degree of Gemini, May 22, 1639; it consisted of six sheets of paper. But that manuscript I gave {91}unto my most munificent patron and ever bountiful friend, William Pennington, of Muncaster in Cumberland, Esq., a wise and excellently learned person; who, from the year 1634, even till he died, continued unto me the most

grateful person I ever was acquainted with. I became acquainted with him by means of Davy Ramsey.

Oh! most noble Esquire, let me now beg your pardon, if I digress for some small time, in commemorating his bounty unto me, and my requital of his friendship, by performing many things successfully for his advantage.

In 1639 he was made captain, and served his Majesty in his then wars against the Scots; during which time a farmer's daughter being delivered of a bastard, and hearing, by report, that he was slain, fathered the child upon him. Shortly after he returned, most woefully vexed to be thus abused, when {92}absent. The woman was countenanced by some gentlemen of Cumberland, in this her villany against him; so that, notwithstanding he had warrants to attach her body, he could never discover her: but yet, hunting her from one place to another, her friends thought it most convenient to send her to London, where she might be in most safety. She came up to the city, and immediately I had notice thereof, and the care of that matter was left unto me. I procured the Lord Chief Justice Bramston's warrant, and had it lying dormant by me. She had not been in the city above one fortnight, but that I, going casually to the clerk of the assizes' office for Cumberland, saw there an handsome woman; and hearing of her speak the northern tone, I concluded she was the party I did so want. I rounded the clerk in his ear, and told him I would give him five shillings to hold the {93}woman in chat till I came again, for I had a writing concerned her. I hasted for my warrant, and a constable, and returned into the office, seized her person before the clerk of the assizes, who was very angry with me: it was then sessions at Old-Bayley, and neither Judge nor Justice to be found. At night we carried her before the Recorder, Gardner. It being Saturday at night, she, having no bail, was sent to Bridewell, where she remained till Monday. On Monday morning, at the Old-Bayley, she produced bail; but I desiring of the Recorder some time to enquire after the bail, whether they were sufficient, returned presently, and told him

one of the bail was a prisoner in Ludgate, the other a very poor man. At which he was so vexed, that he sent her to Newgate, where she lay all that week, until she could please me with good sureties; which then {94}she did, and so was bound over to appear at the next assizes in Cumberland; which she did, and was there sentenced to be whipped, and imprisoned one whole year.

This action infinitely pleased Mr. Pennington, who thought I could do wonders; and I was most thankfully requited for it. All the while of this scandalous business, do what he could, he could not discover what persons they were that supported her; but the woman's father coming to town, I became acquainted with him, by the name of Mr. Sute, merchant; invited him to a dinner; got George Farmer with me; when we so plied him with wine, he could neither see or feel. I paid the reckoning, twenty-two shillings. But next morning the poor man had never a writing or letter in his pocket. I sent them down to my friend, who thereby discovered the plots of several gentlemen in the business; {95}after which, Mr. Sute returned to his old name again.

Mr. Pennington was a true royalist, whom Charles the Second made one of his Commissioners of Array for Cumberland. Having directions from me continually how matters did and would go betwixt the King and Parliament, he acted warily, and did but sign one only warrant of that nature, and then gave over. When the times of sequestrations came, one John Musgrave, the most bold and impudent fellow, and most active of all the north of England, and most malicious against my friend, had got this warrant under Mr. Pennington's hand into his custody; which affrighted my friend, and so it might, for it was cause enough of sequestration, and would have done it. Musgrave intending himself great matters out of his estate, I was made acquainted herewith. Musgrave {96}being in London, by much ado, I got acquainted with him, pretending myself a bitter enemy against Pennington, whereat he very heartily rejoiced; and so we appointed one night to meet at the Five Bells, to compare notes; for I pretended much.

We did meet, and he very suddenly produced upon the table all his papers, and withal, the warrant of array unto which my friend had set his hand; which when I saw, 'I marry,' said I, 'this is his hand I will swear; now have at all come, the other cup, this warrant shall pay for all.' I observed where the warrant lay upon the table, and, after some time took occasion ignorantly to let the candle fall out, which whilst he went to light again at the fire, I made sure of the warrant, and put it into my boot; he never missing it of eight or ten days; about which time, I believe, it was above half way towards Cumberland, {97}for I instantly sent it by the post, with this friendly caveat, '*Sin no more*.' Musgrave durst not challenge me in those times, and so the business was ended very satisfactory to his friend, and no less to myself.

He was, besides, extremely abused by one Isaac Antrobus, parson of Egremond, a most evil liver, bold, and very rich; at last he procured a minister of that country, in hope of the parsonage, to article against him in London, before the committee of plundered ministers. I was once more invited to solicit against Antrobus, which I did upon three or more articles.

I. That Antrobus baptized a cock, and called him Peter.

II. He had knowledge of such a woman and of her daughter, *viz.* of both their bodies, {98}in as large a manner as ever of his own wife.

III. Being drunk, a woman took a cord and tied it about his privy members unto a manger in a stable.

IV. Being a continual drunkard.

V. He never preached, &c.

Antrobus was now become a great champion for the Parliament; but, at the day of hearing, I had procured abundance of my friends to be there; for the godly, as they termed themselves, sided with him; the present Master of the Rolls was Chairman that day, Sir Harbottle Grimston.

Who, hearing the foulness of the cause, was very much ashamed thereof. I remember Antrobus, being there, pleaded he was in his natural condition when he acted so ungraciously.

{99}

'What condition were you in,' said the Chairman, 'when you lay with mother and daughter?'

'There is no proof of that,' saith he.

'None but your own confession,' said the Chairman, 'nor could any tell so well.'

'I am not given to drunkenness,' quoth he. 'He was so drunk within this fortnight,' quoth I, 'he reeled from one side of the street to the other; here is the witness to prove it:' who, presently, before the committee, being sworn, made it good, and named the place and street where he was drunk. So he was adjudged scandalous, and outed of his benefice, and our minister had the parsonage.

You cannot imagine how much the routing of this drunken parson pleased Mr. Pennington, who paid all charges munificently and thankfully.

{100}

But now follows the last and greatest kindness I ever did him. Notwithstanding the committee for sequestrations in Cumberland were his very good friends, yet the sub-sequestrators, of their own heads, and without order, and by strength of arms, secured

his irons, his wood, and so much of his personal estate as was valued at seven thousand pounds. Now had I complaint upon complaint: would I suffer my old friend to be thus abused? it was in my power to free him from these villains.

I hereupon advised what was best to do, and was counselled to get Mr. Speaker Lenthall's letter to the sub-sequestrators, and command them to be obedient to the committee of the county.

Whereupon, I framed a letter myself, unto the sub-sequestrators directed, and with it, myself and Mr. Laurence Maydwell (whom {101}yourself well knew) went to Mr. Speaker, unto whom we sufficiently related the stubbornness of the officers of Cumberland; their disobedience to the committee; and then shewed him the letter, which when he had read over, he most courteously signed, adding withal, that if they proceeded further in sequestring Mr. Pennington, he would command a Serjeant at Arms to bring them up to answer their contempts: I immediately posted that letter to my friend, which when the absurd fellows received, they delivered him possession of his goods again; and, for my pains, when he came to London, gave me one hundred pounds; he died in 1652, of a violent fever. I did carefully, in 1642 and 1643, take notice of every grand action which happened betwixt King and Parliament, and did first then incline to believe, that as all sublunary affairs did depend upon superior {102}causes, so there was a possibility of discovering them by the configurations of the superior bodies; in which way making some essays in those two years, I found encouragement to proceed further, which I did; I perused the writings of the ancients, but therein they were silent, or gave no satisfaction; at last, I framed unto myself that method, which then and since I follow, which, I hope, in time may be more perfected by a more penetrating person than myself.

In 1643, I became familiarly known to Sir Bulstrode Whitlocke, a member of the House of Commons; he being sick, his urine was brought unto me by Mrs. Lisle,[11] wife to

John {103}Lisle, afterwards one of the keepers of the Great Seal; having set my figure, I returned answer, the sick for that time would recover, but by means of a surfeit would dangerously relapse within one month; which he did, by eating of trouts at Mr. Sand's house, near Leatherhead in Surrey. Then I went daily to visit him, Dr. Prideau despairing of his life; but I said there was no danger thereof, and that he would be sufficiently well in five or six weeks; and so he was.

Footnote 11:(return)

She was afterwards beheaded at Winchester, for harbouring one Nelthrop, a rebel in the Duke of Monmouth's army 1685. She had made herself remarkable, by saying at the martyrdom of King Charles I, 1648, 'that her blood leaped within her to see the tyrant fall;' for this, when she fell into the state trap, she neither did nor could expect favour from any of that martyr's family.

In 1644, I published *Merlinus Anglicus Junior* about April. I had given one day the copy thereof unto the then Mr. Whitlocke, who by accident was reading thereof in the House of Commons: ere the Speaker took {104}the chair, one looked upon it, and so did many, and got copies thereof; which when I heard, I applied myself to John Booker to license it, for then he was licenser of all mathematical books; I had, to my knowledge, never seen him before; he wondered at the book, made many impertinent obliterations, framed many objections, swore it was not possible to distinguish betwixt King and Parliament; at last licensed it according to his own fancy; I delivered it unto the printer, who being an arch Presbyterian, had five of the ministry to inspect it, who could make nothing of it, but said it might be printed, for in that I meddled not with their Dagon. The first impression was sold in less than one week; when I presented some to the members of Parliament, I complained of John Booker the licenser, who had defaced my book; they gave me order forthwith to reprint {105}it as I would, and let them know if any durst resist me in the reprinting, or adding what I thought fit; so the second time it came forth as I would have it.

I must confess, I now found my scholar Humphreys's words to be true concerning John Booker, whom at that time I found but moderately versed in astrology; nor could he take the circles of position of the planets, until in that year I instructed him. After my *Introduction* in 1647 became publick, he amended beyond measure, by study partly, and partly upon emulation to keep up his fame and reputation; so that since 1647, I have seen some nativities by him very judiciously performed. When the printer presented him with an *Introduction* of mine, as soon as they were forth of the press; 'I wish,' saith he, 'there was never another but this in England, conditionally I gave one hundred pounds for {106}this.' After that time we were very great friends to his dying day.

In June, 1644, I published *Supernatural Sight*; and, indeed, if I could have procured the dull stationer to have been at charges to have cut the *icon* or form of that prodigious apparition, as I had drawn it forth, it would have given great satisfaction; however, the astrological judgment thereupon had its full event in every particular.

That year also I published the *White King's Prophecy*, of which there were sold in three days eighteen hundred, so that it was oft reprinted: I then made no commentary upon it.

In that year I printed the *Prophetical Merlin*, and had eight pounds for the copy.

I had then no farther intention to trouble the press any more, but Sir Richard Napper having received one of Captain Wharton's {107}*Almanacks* for 1645, under the name Naworth, he came unto me: 'Now, Lilly, you are met withal, see here what Naworth writes.' The words were, he called me 'an impudent senseless fellow, and by name William Lilly.'

Before that time, I was more Cavalier than Roundhead, and so taken notice of; but after that I engaged body and soul in the cause of Parliament, but still with much affection to his Majesty's person and unto monarchy, which I ever loved and approved beyond any government whatsoever; and you will find in this story many passages of civility which

I did, and endeavoured to do, with the hazard of my life, for his Majesty: but God had ordered all his affairs and counsels to have no successes; as in the sequel will appear.

To vindicate my reputation, and to cry quittance with Naworth, against whom I was {108}highly incensed, to work I went again for *Anglicus*, 1645; which as soon as finished I got to the press, thinking every day one month till it was publick: I therein made use of the King's nativity, and finding that his ascendant was approaching to the quadrature of Mars, about June, 1645, I gave this unlucky judgment; 'If now we fight, a victory stealeth upon us;' and so it did in June, 1645, at Naseby, the most fatal overthrow he ever had.

In this year, 1645, I published a treatise called the *Starry Messenger*, with an interpretation of three suns seen in London, 29th May, 1644, being Charles the Second's birthday: in that book I also put forth an astrological judgment concerning the effects of a solar eclipse, visible the 11th of August, 1645. Two days before its publishing, my antagonist, Captain Wharton, having given {109}his astronomical judgment upon his Majesty's present march from Oxford; therein again fell foul against me and John Booker: Sir Samuel Luke, Governor of Newportpagnel, had the thing came to his garrison from Oxford, which presently was presented unto my view. I had but twelve hours, or thereabout, to answer it, which I did with such success as is incredible; and the printer printed both the *March* and my answer unto it, and produced it to sight, with my *Starry Messenger*, which came forth and was made publick the very day of the Parliament's great victory obtained against his Majesty in person at Naseby, under the conduct of the Lord Thomas Fairfax.

That book no sooner appeared, but within fourteen days complaint was made to the committee of examinations, Miles Corbet then being Chairman, my mortal enemy, he {110}who after was hanged, drawn, and quartered, for being one of the King's Judges; he grants his warrant, and a messenger to the Serjeant at Arms seizeth my person. As I

was going to Westminster with the messenger, I met Sir Philip Stapleton, Sir Christopher Wray, Mr. Denzil Hollis, Mr. Robert Reynolds, who, by great fortune, had the *Starry Messenger* sheet by sheet from me as it came from the press. They presently fell a smiling at me; 'Miles Corbet, Lilly, will punish thee soundly; but fear nothing, we will dine, and make haste to be at the committee time enough to do the business;' and so they most honourably performed; for they, as soon as they came, sat down, and put Mr. Reynolds purposely into the chair, and I was called in; but Corbet being not there, they bid me withdraw until he came; which when he did, I was commanded to appear, and Corbet {111}desired to give the cause of my being in restraint, and of the committee's order. Mr. Reynolds was purposely put into the chair, and continued till my business was over.

Corbet produced my *Anglicus* of 1645, and said there were many scandalous passages therein against the Commissioners of Excise in London. He produced one passage, which being openly read by himself, the whole committee adjudged it to signify the errors of sub-officers, but had no relation to the Commissioners themselves, which I affirmatively maintained to be the true meaning as the committee declared.

Then Corbet found out another dangerous place, as he thought, and the words were thus in the printed book—'In the name of the Father, Son, and Holy Ghost, will not the Excise pay the soldiers?'

Corbet very ignorantly read, 'will not the {112}Eclipse pay soldiers?' at which the Committee fell heartily to laugh at him, and so he became silent.

There was a great many Parliament men there; the chamber was full. 'Have you any more against Mr. Lilly?' cried the chairman.

'Yes,' saith the Sollicitor for the Excise, 'since his *Starry Messenger* came forth we had our house burnt, and the Commissioners pulled by their cloaks in the Exchange.' 'Pray,

sir, when was this,' asked old Sir Robert Pye, 'that the house was burnt, and the Aldermen abused?' 'It was in such a week,' saith he. 'Mr. Lilly, when came the book forth?' 'The very day of Naseby fight,' answered Mr. Reynolds, 'nor needs he be ashamed of writing it: I had it daily as it came forth of the press: it was then found the house to be burnt, and the Aldermen {113}abused, twelve days before the *Starry Messenger* came forth.' 'What a lying fellow art thou,' saith Sir Robert Pye, 'to abuse us so!' This he spoke to the Sollicitor. Then stood up one Bassell, a merchant: he inveighed bitterly against me, being a Presbyterian, and would have had my books burnt. 'You smell more of a citizen than a scholar,' replied Mr. Francis Drake. I was ordered to withdraw, and by and by was called in, and acquainted the committee did discharge me. But I cried with a loud voice, 'I was under a messenger;' whereupon the committee ordered him or the Serjeant at Arms not to take any fees; Mr. Reynolds saying, 'Literate men never pay any fees.'

But within one week after, I was likely to have had worse success, but that the before-named gentlemen stoutly befriended me. In my Epistle of the *Starry Messenger*, I had {114}been a little too plain with the committee of Leicestershire; who thereof made complaint unto Sir Arthur Hazelrigg, Knight for that county; he was a furious person, and made a motion in the House of Commons against me, and the business was committed to that committee, whereof Baron Rigby was chairman. A day was assigned to hear the matter; in the morning whereof, as I passed by Mr. Pullen's shop in St. Paul's Church-yard, Pullen bad 'God be with you,' and named me by name. Mr. Selden being there, and hearing my name, gave direction to call me unto him, where he acquaints me with Hazelrigg's humour and malice towards me, called for the *Starry Messenger*, and having read over the words mentioning that committee, he asked me how I would answer them? I related what I would have said, but he contradicted me, and acquainted me {115}what to say, and how to answer. In the afternoon I went to appear, but there was no committee set, or would sit; for both Mr. Reynolds and Sir Philip Stapleton, and

my other friends, had fully acquainted Baron Rigby with the business, and desired him not to call upon me until they appeared; for the matter and charge intended against me was very frivolous, and only presented by a cholerick person to please a company of clowns, meaning the committee of Leicester. Baron Rigby said, if it were so he would not meddle with the matter, but exceedingly desired to see me. Not long after he met Sir Arthur, and acquainting him what friends appeared for me, said, 'I will then prosecute him no further.'

All the ancient astrologers of England were much startled and confounded at my manner of writing, especially old Mr. William Hodges, {116}who lived near Wolverhampton in Staffordshire, and many others who understood astrology competently well, as they thought. Hodges swore I did more by astrology than he could by the crystal, and use thereof, which indeed he understood as perfectly as any one in England. He was a great royalist, but could never hit any thing right for that party, though he much desired it: he resolved questions astrologically; nativities he meddled not with; in things of other nature, which required more curiosity, he repaired to the crystal: his angels were Raphael, Gabriel, and Uriel: his life answered not in holiness and sanctity to what it should, having to deal with those holy angels. Being contemporary with me, I shall relate what my partner John Scott, the same Scott as is before-mentioned, affirmed of him. John Scott was a little skilful in surgery and physick, {117}so was Will Hodges, and had formerly been a school-master. Scott having some occasions into Staffordshire, addressed himself for a month or six weeks to Hodges, assisted him to dress his patients, let blood, &c. Being to return to London, he desired Hodges to shew him the person and feature of the woman he should marry. Hodges carries him into a field not far from his house, pulls out his crystal, bids Scott set his foot to his, and, after a while, wishes him to inspect the crystal, and observe what he saw there. 'I see,' saith Scott, 'a ruddy complexioned wench in a red waistcoat, drawing a can of beer.' 'She must be your wife,' said Hodges. 'You are mistaken, Sir,' said Scott. 'I am, so soon as I come to London, to

marry a tall gentlewoman in the Old Bailey.' 'You must marry the red waistcoat,' said Hodges. Scott leaves the country, {118}comes up to London, finds his gentlewoman married: two years after going into Dover, in his return, he refreshed himself at an inn in Canterbury, and as he came into the hall, or first room thereof, he mistook the room, and went into the buttery, where he espied a maid, described by Hodges, as before said, drawing a can of beer, &c. He then more narrowly viewing her person and habit, found her, in all parts, to be the same Hodges had described; after which he became a suitor unto her, and was married unto her; which woman I have often seen. This Scott related unto me several times, being a very honest person, and made great conscience of what he spoke. Another story of him is as followeth, which I had related from a person which well knew the truth of it.

A neighbour gentleman of Hodges lost his {119}horse; who having Hodges's advice for recovery of him, did again obtain him. Some years after, in a frolick, he thought to abuse him, acquainting a neighbour therewith, viz., that he had formerly lost a horse, went to Hodges, recovered him again, but saith it was by chance; I might have had him without going unto him: 'Come, let's go, I will now put a trick upon him; I will leave some boy or other at the town's-end with my horse, and then go to Hodges and enquire for him.' He did so, gave his horse to a youth, with orders to walk him till he returned. Away he goes with his friend, salutes Mr. Hodges, thanks him for his former courtesy, and now desires the like, having lost a horse very lately. Hodges, after some time of pausing, said; 'Sir, your horse is lost, and never to be recovered.' 'I thought what skill you had,' replies the gallant, 'my horse is walking {120}in a lane at the town's-end.' With that Hodges swore (as he was too much given unto that vice) 'your horse is gone, and you will never have him again.' The gentleman departed in great derision of Hodges, and went where he left his horse: when he came there, he found the boy fast asleep upon the ground, the horse gone, the boy's arm in the bridle.

He returns again to Hodges, desiring his aid, being sorry for his former abuse. Old Will swore like a devil, 'be gone, be gone; go look for your horse.' This business ended not so; for the malicious man brought Hodges into the star-chamber, bound him over to the assizes, put Hodges to great expences: but, by means of the Lord Dudley, if I remember aright, or some other person thereabouts, he overcame the gentleman, and was acquitted.

{121}

Besides this, a gentlewoman of my acquaintance, and of credit, in Leicestershire, having lost a pillion-cloth, a very new one, went to desire his judgment. He ordered her such a day to attend at Mountsorrel in Leicestershire, and about twelve o'clock she should see her pillion-cloth upon a horse, and a woman upon it. My friend attended the hour and place; it being told, she must needs warm herself well, and then enquired if any passengers had lately gone by the inn? Unto whom answer was made, there passed by whilst she was at the fire, about half an hour before, a man, and a woman behind him, on horse-back. Inquiring of what colour the pillion-cloth was of; it was answered, directly of the colour my friend's was: they pursued, but too late.

In those times, there lived one William Marsh in Dunstable, a man of godly life and {122}upright conversation, a Recusant. By astrology he resolved thievish questions with great success; that was his utmost sole practice. He was many times in trouble; but by Dr. Napper's interest with the Earl of Bolingbroke, Lord Wentworth, after Earl of Cleveland, he still continued his practice, the said Earl not permitting any Justice of Peace to vex him.

This man had only two books, *Guido* and *Haly* bound together; he had so mumbled and tumbled the leaves of both, that half one side of every leaf was torn even to the middle. I was familiar with him for many years: he died about 1647.

A word or two of Dr. Napper, who lived at Great Lindford in Buckinghamshire, was parson, and had the advowson thereof. He descended of worshipful parents, and this you must believe; for when Dr. Napper's {123}brother, Sir Robert Napper, a Turkey merchant, was to be made a Baronet in King James's reign, there was some dispute whether he could prove himself a gentleman for three or more descents. 'By my saul,' saith King James, 'I will certify for Napper, that he is of above three hundred years standing in his family, all of them, by my saul, gentlemen,' &c. However, their family came into England in King Henry the Eighth's time. The parson was Master of Arts; but whether doctorated by degree or courtesy, because of his profession, I know not. Miscarrying one day in the pulpit, he never after used it, but all his life-time kept in his house some excellent scholar or other to officiate for him, with allowance of a good salary: he out-went Forman in physick and holiness of life; cured the falling-sickness {124}perfectly by constellated rings, some diseases by amulets, &c.

A maid was much afflicted with the falling sickness, whose parents applied themselves unto him for cure: he framed her a constellated ring, upon wearing whereof, she recovered perfectly. Her parents acquainted some scrupulous divines with the cure of their daughter: 'The cure is done by inchantment,' say they. 'Cast away the ring, it's diabolical; God cannot bless you, if you do not cast the ring away.' The ring was cast into the well, whereupon the maid became epileptical as formerly, and endured much misery for a long time. At last her parents cleansed the well, and recovered the ring again; the maid wore it, and her fits took her no more. In this condition she was one year or two; which the Puritan ministers {125}there adjoining hearing, never left off, till they procured her parents to cast the ring quite away; which done, the fits returned in such violence, that they were enforced to apply to the Doctor again, relating at large the whole story, humbly imploring his once more assistance; but he could not be procured to do any thing, only said, those who despised God's mercies, were not capable or worthy of enjoying them.

I was with him in 1632, or 1633, upon occasion. He had me up into his library, being excellently furnished with very choice books: there he prayed almost one hour; he invocated several angels in his prayer, viz.[12] Michael, Gabriel, Raphael, Uriel, &c. We parted.

Footnote 12:(return)

The collect read on Michaelmas-day, seems to allow of praying to angels. At some times, upon great occasions, he had conference with Michael, but very rarely.

{126}

He instructed many ministers in astrology, would lend them whole cloak-bags of books; protected them from harm and violence, by means of his power with the Earl of Bolingbroke.[13] He would confess my master Evans knew more than himself in some things: and some time before he died, he got his cousin Sir Richard to set a figure to see when he should die. Being brought him; 'Well,' he said, 'the old man will live this winter, but in the spring he will die; welcome Lord Jesus, thy will be done.' He had many enemies: Cotta, Doctor of physick in Northampton, wrote a sharp book of witchcraft, wherein, obliquely, he bitterly inveighed against the Doctor.

Footnote 13:(return)

Lord Wentworth, after Earl of Cleveland.

In 1646, I printed a collection of Prophecies, with the explanation and verification of {127}Aquila, or the *White King's Prophecy*; as also the nativities of Bishop Laud and Thomas Earl of Strafford, and a most learned speech by him intended to have been spoke upon the scaffold. In this year 1646, after a great consideration, and many importunities, I began to fix upon thoughts of an *Introduction unto Astrology*, which was very much wanting, and as earnestly longed for by many persons of quality. Something also much occasioned and hastened the impression, viz. the malevolent

barking of Presbyterian ministers in their weekly sermons, reviling the professors thereof, and myself particularly by name.

Secondly, I thought it a duty incumbent upon me, to satisfy the whole kingdom of the lawfulness thereof, by framing a plain and easy method for any person but of indifferent capacity to learn the art, and instruct himself {128}therein, without any other master than my *Introduction*; by which means, when many understood it, I should have more partners and assistants to contradict all and every antagonist.

Thirdly, I found it best as unto point of time, because many of the soldiers were wholly for it, and many of the Independant party; and I had abundance of worthy men in the House of Commons, my assured friends, no lovers of Presbytery, which then were in great esteem, and able to protect the art; for should the Presbyterian party have prevailed, as they thought of nothing less than to be Lords of all, I knew well they would have silenced my pen annually, and committed the *Introduction* unto everlasting silence.

Fourthly, I had something of conscience touched my spirit, and much elevated my conceptions, believing God had not bestowed {129}those abilities upon me, to bury them under a bushel; for though my education was very mean, yet, by my continual industry, and God's great mercy, I found myself capable to go forward with the work, and to commit the issue thereof unto Divine Providence.

I had a hard task in hand to begin the first part hereof, and much labour I underwent to methodize it as it is.

I ingenuously confess unto you (Arts' great Mecænas, noble Esquire Ashmole,) no mortal man had any share in the composition or ordering of the first part thereof, but my only self. You are a person of great reading, yet I well know you never found the least trace thereof in any author yet extant.

In composing, contriving, ordering, and framing thereof (viz. the first part) a great part of that year was spent. I again perused all, or most, authors I had, sometimes adding, {130}at other times diminishing, until at last I thought it worthy of the press. When I came to frame the second part thereof, having formerly collected out of many manuscripts, and exchanged rules with the most able professors I had acquaintance with, in transcribing those papers for impression, I found, upon a strict inquisition, those rules were, for the most part, defective; so that once more I had now a difficult labour to correct their deficiency, to new rectify them according to art; and lastly, considering the multiplicity of daily questions propounded unto me, it was as hard a labour as might be to transcribe the papers themselves with my own hand. The desire I had to benefit posterity and my country, at last overcame all difficulties; so that what I could not do in one year, I perfected early the next year, 1647; and then in that year, viz. 1647, I {131}finished the third book of[14] nativities,[15] during the composing whereof, for seven whole weeks, I was shut up of the plague, burying in that time two maid-servants thereof; yet towards November that year, the Introduction, called by the name of *Christian Astrology*, was made publick. There being, in those times, some smart difference between the army and the Parliament, the head-quarters of the army were at Windsor, whither I was carried with a coach and four horses, and John Booker with me. We were welcome thither, and feasted in a garden where General Fairfax lodged. We were brought {132}to the General, who bid us kindly welcome to Windsor; and, in effect, said thus much:

Footnote 14:(return)

The name of the person whose nativity is directed and judged, is Mr. Thompson, whose father had been some time an inn-keeper at the White-Hart in Newark.

Footnote 15:(return)

I devised the forms and fashions of the several schemes. E.A.

'That God had blessed the army with many signal victories, and yet their work was not finished. He hoped God would go along with them until his work was done. They sought not themselves, but the welfare and tranquillity of the good people, and whole nation; and, for that end, were resolved to sacrifice both their lives and their own fortunes. As for the art we studied, he hoped it was lawful and agreeable to God's word: he understood it not; but doubted not but we both feared God; and therefore had a good opinion of us both.' Unto his speech I presently made this reply:

'My Lord, I am glad to see you here at this time.

'Certainly, both the people of God, and all others of this nation, are very sensible of {133}God's mercy, love, and favour unto them, in directing the Parliament to nominate and elect you General of their armies, a person so religious, so valiant.

'The several unexpected victories obtained under your Excellency's conduct, will eternize the same unto all posterity.

'We are confident of God's going along with you and your army, until the great work for which he ordained you both, is fully perfected; which we hope will be the conquering and subversion of your's and the Parliament's enemies, and then a quiet settlement and firm peace over all the nation, unto God's glory, and full satisfaction of tender consciences.

'Sir, as for ourselves, we trust in God; and, as Christians, believe in him. We do not study any art but what is lawful, and consonant to the scriptures, fathers, and antiquity; {134}which we humbly desire you to believe,' &c.

This ended, we departed, and went to visit Mr. Peters the minister, who lodged in the castle, whom we found reading an idle pamphlet come from London that morning.

zaid n. adwan

'Lilly, thou art herein,' says he. 'Are not you there also?' I replied. 'Yes, that I am,' quoth he.—The words concerning me were these:

From th' oracles of the Sibyls so silly,
The curst predictions of William Lilly,
And Dr. Sybbald's Shoe-lane Philly,
Good Lord, deliver me.

After much conference with Hugh Peters, and some private discourse betwixt us two, not to be divulged, we parted, and so came back to London.

King Charles the First, in the year 1646, {135}April 27, went unto the Scots, then in this nation. Many desired my judgment, in time of his absence, to discover the way he might be taken: which I would never be drawn unto, or give any direction concerning his person.

There were many lewd Mercuries printed both in London and Oxford, wherein I was sufficiently abused, in this year, 1646. I had then my ascendant *ad* [symbol: Gemini] [symbol: aspect "conjunction"], and [symbol: Moon] *ad propriun*. The Presbyterians were, in their pulpits, as merciless as the Cavaliers in their pamphlets.

About this time, the most famous mathematician of all Europe,[16] Mr. William Oughtred, parson of Aldbury in Surry, was in danger {136}of sequestration by the Committee of or for plundered ministers; (*Ambo-dexters* they were;) several inconsiderable articles were deposed and sworn against him, material enough to have sequestered him, but that, upon his day of hearing, I applied myself to Sir Bolstrode Whitlock, and all my own old friends, who in such numbers appeared in his behalf, that though the chairman and many other Presbyterian members were stiff against him, yet he was cleared by the major number. The truth is, he had a considerable parsonage, and that only was enough to sequester any moderate judgment: he was also well known to affect his Majesty. In

these times many worthy ministers lost their livings or benefices, for not complying with the *Three-penny Directory*. Had you seen (O noble Esquire) what pitiful ideots were prefered into sequestrated church-benefices, you {137}would have been grieved in your soul; but when they came before the classis of divines, could those simpletons but only say, they were converted by hearing such a sermon, such a lecture, of that godly man Hugh Peters, Stephen Marshall, or any of that gang, he was presently admitted.

Footnote 16:(return)

This gentleman I was very well acquainted with, having lived at the house over-against his, at Aldbury in Surrey, three or four years. E.A.

In 1647, I published the *World's Catastrophe*, the *Prophecies of Ambrose Merlin*, with the *Key* wherewith to unlock those obstruse Prophecies; also *Trithemius of the Government of the World by the presiding Angels*; these came forth all in one book.

The two first were exquisitely translated by yourself, (most learned Sir) as I do ingenuously acknowledge in my *Epistle unto the Reader*, with a true character of the worth and admirable parts, unto which I refer any that do desire to read you perfectly delineated. I was once resolved to have continued {138}*Trithemius* for some succeeding years, but multiplicity of employment impeded me. The study required, in that kind of learning, must be sedentary, of great reading, sound judgment, which no man can accomplish except he wholly retire, use prayer, and accompany himself with angelical consorts.

His Majesty Charles the First, having entrusted the Scots with his person, was, for money, delivered into the hands of the English Parliament, and, by several removals, was had to Hampton-Court, about July or August 1647; for he was there, and at that time when my house was visited with the plague. He was desirous to escape from the soldiery, and to obscure himself for some time near London, the citizens whereof began

now to be unruly, and alienated in affection from the Parliament, inclining wholly to his Majesty, and very averse to the army. His {139}Majesty was well informed of all this, and thought to make good use hereof; besides, the army and Parliament were at some odds, who should be masters. Upon the King's intention to escape, and with his consent, Madam Whorewood (whom you knew very well, worthy Esquire) came to receive my judgment, viz. In what quarter of this nation he might be most safe, and not to be discovered until himself pleased.

When she came to my door, I told her I would not let her come into my house for I buried a maid-servant of the plague very lately. 'I fear not the plague, but the pox,' quoth she; so up we went. After erection of my figure, I told her about twenty miles (or thereabouts) from London, and in Essex, I was certain he might continue undiscovered. She liked my judgment very well; and, being herself of a sharp judgment, remembered {140}a place in Essex about that distance, where was an excellent house, and all conveniences for his reception. Away she went, early next morning, unto Hampton-Court, to acquaint his Majesty; but see the misfortune: He, either guided by his own approaching hard fate, or misguided by Ashburnham,[17] went away in the night-time westward, and surrendered himself to Hammond, in the Isle of Wight.

Footnote 17:(return)

This Ashburnham was turned out of the House of Commons the 3d of November, 1667, for taking a bribe of five hundred pounds of the merchants. I was informed hereof 26th November, 1667.

Whilst his Majesty was at Hampton-Court Alderman Adams sent his Majesty one thousand pounds in gold, five hundred whereof he gave Madam Whorewood. I believe I had twenty pieces of that very gold for my share.

{141}

I have something more to write of Charles the First's misfortunes, wherein I was concerned; the matter happened in 1648, but I thought good to insert it here, having after this no more occasion to mention him.

His Majesty being in Carisbrook-Castle in the Isle of Wight, the Kentish men, in great numbers, rose in arms, and joined with the Lord Goring; a considerable number of the best ships revolted from the Parliament; the citizens of London were forward to rise against the Parliament; his Majesty laid his design to escape out of prison, by sawing the iron bars of his chamber window; a small ship was provided, and anchored not far from the castle to bring him into Sussex; horses were provided ready to carry him through Sussex into Kent, so that he might be at the head of the army in Kent, and from thence to march immediately to London, where {142}thousands then would have armed for him. The Lady Whorewood came to me, acquaints me herewith. I got G. Farmer (who was a most ingenious lock-smith, and dwelt in Bowlane) to make a saw to cut the iron bars in sunder, I mean to saw them, and aqua fortis besides. His Majesty in a small time did his work; the bars gave liberty for him to go out; he was out with his body till he came to his breast; but then his heart failing, he proceeded no farther: when this was discovered, as soon after it was, he was narrowly looked after, and no opportunity after that could be devised to enlarge him. About September the Parliament sent their Commissioners with propositions unto him into the Isle of Wight, the Lord William Sea being one; the Lady Whorewood comes again unto me from him or by his consent, to be directed: After perusal of my figure, I told her the {143}Commissioners would be there such a day; I elected a day and hour when to receive the Commissioners and propositions; and as soon as the propositions were read, to sign them, and make haste with all speed to come up with the Commissioners to London. The army being then far distant from London, and the city enraged stoutly against them, he promised he would do so. That night the Commissioners came, and old Sea and his Majesty had private conference till one in the morning: the King acquaints Sea with his intention, who

clearly dissuaded him from signing the propositions, telling him they were not fit for him to sign; that he had many friends in the House of Lords, and some in the House of Commons; that he would procure more, and then they would frame more easy propositions. This flattery of this unfortunate Lord occasioned his Majesty to {144}wave the advice I and some others that wished his prosperity had given, in expectation of that which afterwards could never be gained. The army having some notice hereof from one of the Commissioners, who had an eye upon old Sea, hasted unto London, and made the citizens very quiet; and besides, the Parliament and army kept a better correspondency afterwards with each other.

Whilst the King was at Windsor-Castle, once walking upon the leads there, he looked upon Captain Wharton's *Almanack*: 'My book,' saith he, 'speaks well as to the weather:' One William Allen standing by; 'what,' saith he, 'saith his antagonist, Mr. Lilly?' 'I do not care for Lilly,' said his Majesty, 'he hath been always against me,' and became a little bitter in his expressions. 'Sir,' saith Allen, 'the man is an honest man, and writes but what his art informs {145}him.' 'I believe it,' said his Majesty, 'and that Lilly understands astrology as well as any man in Europe.' *Exit Rex Carolus.*

In 1648 I published a *Treatise of the Three Suns*, seen the winter preceding; as also an Astrological Judgment upon a Conjunction of Saturn and Mars 28 June, in 11 degrees 8 minutes of Gemini.

I commend unto your perusal that book and the *Prophetical Merlin*, which, seriously considered, (Oh worthy Esquire) will more instruct your judgement (*De generalibus contingentibus Mundi*) than all the authors you yet ever met with.

In this year, for very great considerations, the Council of State gave me in money fifty pounds, and a pension of one hundred pounds *per Annum*, which for two years I received, but no more: upon some discontents I after would not or did require it. The

cause moving {146}them was this; they could get no intelligence out of France, although they had several agents there for that purpose. I had formerly acquaintance with a secular priest, at this time confessor to one of the Secretaries; unto him I wrote, and by that means had perfect knowledge of the chiefest concernments of France, at which they admired; but I never yet, until this day, revealed the name of the person.

One occasion why I deserted that employment was, because Scott, who had eight hundred pounds *per Annum* for intelligence, would not contribute any occasion to gratify my friend: And another thing was, I received some affront from Gualter Frost their Secretary, one that was a principal minister belonging to the Council of State. Scott was ever my enemy, the other knave died of a gangrene in his arm suddenly after.

{147}

In 1648 and 1649, that I might encourage young students in astrology, I publickly read over the first part of my *Introduction*, wherein there are many things contained, not easily to be understood.

And now we are entered into the year 1649: his Majesty being at St. James's House, in January of that year, I begun its observations thus:

'I am serious, I beg and expect justice; either fear or shame begins to question offenders.

'The lofty cedars begin to divine a thundering hurricane is at hand; God elevates men contemptible.

'Our demigods are sensible we begin to dislike their actions very much in London, more in the country.

zaid n. adwan

'Blessed be God, who encourages his servants, makes them valiant, and of undaunted {148}spirits, to go on with his decrees: upon a sudden, great expectations arise, and men generally believe a quiet and calm time draws nigh.'

In Christmas holidays, the Lord Gray of Grooby and Hugh Peters sent for me to Somerset-House, with directions to bring them two of my Almanacks.—I did so; Peters and he read January's Observations.

'If we are not fools and knaves,' saith he, 'we shall do justice:' then they whispered. I understood not their meaning till his Majesty was beheaded. They applied what I wrote of justice, to be understood of his Majesty, which was contrary to my intention; for Jupiter, the first day of January, became direct; and Libra is a sign signifying Justice; I implored for justice generally upon such as had cheated in their places, being treasurers, and such like officers. I had not then heard the {149}least intimation of bringing the King unto trial, and yet the first day thereof I was casually there, it being upon a Saturday; for going to Westminster every Saturday in the afternoon, in these times, at White-hall I casually met Peters; 'Come, Lilly, wilt thou go hear the King tried?' 'When?' said I. 'Now, just now; go with me.' I did so, and was permitted by the guard of soldiers to pass up to the King's-Bench. Within one quarter of an hour came the Judges, presently his Majesty, who spoke excellently well, and majestically, without impediment in the least when he spoke. I saw the silver top of his staff unexpectedly fall to the ground, which was took up by Mr. Rushworth: and then I heard Bradshaw the Judge say to his Majesty,

'Sir, instead of answering the court, you {150}interrogate their power, which becomes not one in your condition'—

These words pierced my heart and soul, to hear a subject thus audaciously to reprehend his Sovereign, who ever and anon replied with great magnanimity and prudence.

After that his Majesty was beheaded, the Parliament for some years effected nothing either for the publick peace or tranquillity of the nation, or settling religion as they had formerly promised. The interval of time betwixt his Majesty's death and Oliver Cromwel's displacing them, was wholly consumed in voting for themselves, and bringing their own relations to be members of Parliament, thinking to make a trade thereof.

The week, or three or four days before his Majesty's beheading, one Major Sydenham, who had commands in Scotland, came to {151}take his leave of me, and told me the King was to be put to death, which I was not willing to believe, and said, 'I could not be persuaded the Parliament could find any Englishman so barbarous, that would do that foul action.' 'Rather,' saith he, 'than they should want such a man, these arms of mine should do it.' He went presently after into Scotland, and upon the first engagement against them, was slain, and his body miserably cut and mangled.

In 1651 I published *Monarchy or no Monarchy*, and in the latter end thereof some hieroglyphics of my own, composed, at spare time, by the occult learning, many of those types having representations of what should from thence succeed in England, and have since had verification.

I had not that learning from books, or any manuscript I ever yet met withal, it is reduced {152}from a cabal lodging in astrology, but so mysterious and difficult to be attained, that I have not yet been acquainted with any who had that knowledge. I will say no more thereof, but that the asterisms and signs and constellations give greatest light thereunto.

During Bradshaw's being President of the Council of State, it was my happiness to procure Captain Wharton his liberty, which when Bradshaw understood, said, 'I will be an enemy to Lilly, if ever he come before me.' Sir Bolstrode Whitlock broke the ice first

of all on behalf of Captain Wharton: after him the Committee, unto whom his offence had been committed, spoke for him, and said he might well be bailed or enlarged: I had spoken to the Committee the morning of his delivery, who thereupon were so civil unto him, especially Sir William Ermin of Lincolnshire, who at first wondered I appeared not against {153}him; but upon my humble request, my long continued antagonist was enlarged and had his liberty.

In 1651 I purchased one hundred and ten pounds *per Annum* in fee-farm rents for one thousand and thirty pounds. I paid all in ready money; but when his Majesty King Charles the Second, 1660, was restored, I lost it all again, and it returned to the right owner; the loss thereof never afflicted me, for I have ever reduced my mind according to my fortune. I was drawn in by several persons to make that simple purchase. The year I bought it, I had my ascendant directed into a Trine of Jupiter first, and in the same year into the *Cauda Draconis*—my fortune into a quadrant of Mercury. When Colchester was besieged, John Booker and myself were sent for, where we encouraged the soldiers, assuring them the town would very shortly be surrendered, {154}as indeed it was: I would willingly have obtained leave to enter the town, to have informed Sir Charles Lucas, whom I well knew, with the condition of affairs as they then stood, he being deluded by false intelligence: at that time my scholar Humphreys was therein, who many times deluded the Governor with expectation of relief; but failing very many times with his lies, at last he had the bastinado, was put in prison, and inforced to become a soldier; and well it was he escaped so.—During my being there, the steeple of St. Mary's Church was much battered by two cannons purposely placed: I was there one day about three of the clock in the afternoon, talking with the cannoneer, when presently he desired us to look to ourselves, for he perceived by his perspective glass there was a piece charged in the castle against his work, and ready to be discharged. {155}I ran for haste under an old ash-tree, and immediately the cannon-bullet came hissing quite over us. 'No danger now,' saith the gunner, 'but begone, for

there are five more charging,' which was true; for two hours after those cannons were discharged, and unluckily killed our cannoneer and matross. I came the next morning and saw the blood of the two poor men lie upon the planks: we were well entertained at the head-quarters, and after two whole days abiding there, came for London.

But we prosecute our story again, and say that in the year 1652 I purchased my house and some lands in Hersham, in the parish of Walton upon Thames, in the county of Surrey, where I now live; intending by the blessing of God, when I found it convenient, to retire into the country, there to end my days in peace and tranquillity; for in {156}London my practice was such, I had none or very little time afforded me to serve God, who had been so gracious unto me. The purchase of the house and lands, and buildings, stood me in nine hundred and fifty pounds sterling, which I have very much augmented.

The Parliament now grows odious unto all good men, the members whereof became insufferable in their pride, covetousness, self-ends, laziness, minding nothing but how to enrich themselves. Much heart-burning now arose betwixt the Presbyterian and Independant, the latter siding with the army, betwixt whose two judgments there was no medium. Now came up, or first appeared, that monstrous people called Ranters: and many other novel opinions, in themselves heretical and scandalous, were countenanced by members of Parliament, many whereof {157}were of the same judgment. Justice was neglected, vice countenanced, and all care of the common good laid aside. Every judgment almost groaned under the heavy burthen they then suffered; the army neglected; the city of London scorned; the ministry, especially those who were orthodox and serious, honest or virtuous, had no countenance; my soul began to loath the very name of a Parliament, or Parliament-men. There yet remained in the House very able, judicious, and worthy patriots; but they, by their silence, only served themselves: all

was carried on by a rabble of dunces, who being the greater number, voted what seemed best to their non-intelligent fancies.

In this year I published *Annas Tenebrosus*, which book I did not so entitle, because of the great obscurity of the solar eclipse, by so many prattled of to no purpose, but because {158}of those underhand and clandestine counsels held in England by the soldiery, of which I would never, but in generals, give any knowledge unto any Parliament man. I had wrote publickly in 1650, that the Parliament should not continue, but a new government should arise, &c.

In my next year's *Anglicus*, upon rational grounds in astrology, I was so bold as to aver therein, that the Parliament stood upon a tottering foundation, and that the commonalty and soldiery would join together against them.

My *Anglicus* was for a whole week every day in the Parliament House, peeped into by the Presbyterians, one disliking this sentence, another finds another fault, others misliked the whole; so in the end a motion was made, that *Anglicus* should be inspected by the Committee for plundered ministers; {159}which being done, they were to return them to the House, viz. report its errors.

A messenger attached me by a warrant from that Committee; I had private notice ere the messenger came, and hasted unto Mr. Speaker Lenthall, ever my friend. He was exceeding glad to see me, told me what was done; called for *Anglicus*, marked the passages which tormented the Presbyterians so highly. I presently sent for Mr. Warren the printer, an assured Cavalier, obliterated what was most offensive, put in other more significant words, and desired only to have six amended against next morning, which very honestly he brought me. I told him my design was to deny the book found fault with, to own only the six books. I told him, I doubted he would be examined. 'Hang

them,' said he, 'they are all rogues. I'll {160}swear myself to the devil ere they shall have an advantage against you by my oath.'

The day after, I appeared before the Committee, being thirty-six in number that day; whereas it was observed, at other times, it was very difficult to get five of them together. At first they shewed me the true *Anglicus*, and asked if I wrote and printed it. I took the book and inspected it very heedfully; and when I had done so, said thus:

'This is none of my book, some malicious Presbyterian hath wrote it, who are my mortal enemies; I disown it.' The Committee looked upon one another like distracted men, not imagining what I presently did; for I presently pulled out of my pocket six books, and said, 'These I own, the others are counterfeits, published purposely to ruin me.' The Committee were now more vexed than {161}before: not one word was spoke a good while; at last, many of them, or the greatest number of them, were of opinion to imprison me. Some were for Newgate, others for the Gate-House; but then one Brown of Sussex, called the Presbyterian beadle, whom the Company of Stationers had bribed to be my friend, by giving him a new *Book of Martyrs*; he, I say, preached unto the Committee this doctrine, that neither Newgate or the Gate-House were prisons unto which at any time the Parliament sent their prisoners: it was most convenient for the Serjeant at Arms to take me in custody.

Mr. Strickland, who had for many years been the Parliament's Ambassador or Agent in Holland, when he saw how they inclined, spoke thus:

'I came purposely into the Committee this day to see the man who is so famous in {162}those parts where I have so long continued: I assure you his name is famous all over Europe: I come to do him justice. A book is produced by us, and said to be his; he denies it; we have not proved it, yet will commit him. Truly this is great injustice. It is

likely he will write next year, and acquaint the whole world with our injustice; and so well he may. It is my opinion, first to prove the book to be his, ere he be committed.'

Another old friend of mine, Mr. R. spoke thus:

'You do not know the many services this man hath done for the Parliament these many years, or how many times, in our greatest distresses, we applying unto him, he hath refreshed our languishing expectations; he never failed us of comfort in our most unhappy distresses. I assure you his writings {163}have kept up the spirits both of the soldiery, the honest people of this nation, and many of us Parliament men; and now at last, for a slip of his pen (if it were his) to be thus violent against him: I must tell you, I fear the consequence urged out of the book will prove effectually true. It is my counsel, to admonish him hereafter to be more wary, and for the present to dismiss him.'

Notwithstanding any thing that was spoken on my behalf, I was ordered to stand committed to the Serjeant at Arms. The messenger attached my person, said I was his prisoner. As he was carrying me away, he was called to bring me again. Oliver Cromwell, Lieutenant-General of the army, having never seen me, caused me to be produced again, where he stedfastly beheld me for a good space, and then I went with the messenger; but instantly a young clerk of that {164}Committee asks the messenger what he did with me, where's the warrant? until that is signed you cannot seize Mr. Lilly, or shall. Will you have an action of false imprisonment against you? So I escaped that night, but next day obeyed the warrant. That night Oliver Cromwell went to Mr. R. my friend, and said, 'What never a man to take Lilly's cause in hand but yourself? None to take his part but you? He shall not be long there.' Hugh Peters spoke much in my behalf to the Committee; but they were resolved to lodge me in the Serjeant's custody. One Millington, a drunken member, was much my enemy; and so was Cawley and Chichester, a deformed fellow, unto whom I had done several courtesies.

First thirteen days I was a prisoner; and though every day of the Committee's sitting I had a petition to deliver, yet so many {165}churlish Presbyterians still appeared, I could not get it accepted. The last day of the thirteen, Mr. Joseph Ash was made Chairman, unto whom my cause being related, he took my petition, and said I should be bailed in despite of them all, but desired I would procure as many friends as I could to be there. Sir Arthur Hazelrigg, and Major Salloway, a person of excellent parts, appeared for me, and many now of my old friends came in. After two whole hours arguing of my cause by Sir Arthur and Major Salloway, and other friends, the matter came to this point; I should be bailed, and a Committee nominated to examine the printer. The order of the Committee being brought afterwards to him who should be Chairman, he sent me word, do what I would, he would see all the knaves hanged, ere he would examine the printer. This is the truth of the story.

{166}

The 16th of February 1655, my second wife died; for whose death I shed no tears. I had five hundred pounds with her as a portion, but she and her poor relations spent me one thousand pounds. *Gloria Patri, & Filio, & Spiritui Sancto: sicut erat in principio & nunc, & semper, & in sæcula sæculorum*: for the 20th of April 1655, these enemies of mine, viz. Parliament men, were turned out of doors by Oliver Cromwell. A German doctor of physick being then in London, sent me this paper:

Strophe Alcaica: Generoso Domino Gulielmo Lillio Astrologo, de dissoluto nuper Parliamento.

Quod calculasti Sydere prævio,
Miles peregit numine conscio;
Gentis videmus nunc Senatum
Marte togaque gravi levatum.

{167}

In the time of my imprisonment, Mr. Rushworth came to visit me, and told me, the army would do as much as I had predicted unto the Parliament.

In October 1654, I married the third wife, who is signified in my nativity by *Jupiter in Libra*; and she is so totally in her conditions, to my great comfort.

In 1655, I was indicted at Hicks's-Hall by a half-witted young woman. Three several sessions she was neglected, and the Jury cast forth her bill; but the fourth time, they found it against me: I put in bail to traverse the indictment. The cause of the indictment was, for that I had given judgment upon stolen goods, and received two shillings and six-pence.—And this was said to be contrary unto an Act in King James's time made.

This mad woman was put upon this action against me by two ministers, who had framed {168}for her a very ingenious speech, which she could speak without book, as she did the day of hearing the traverse. She produced one woman, who told the court, a son of her's was run from her; that being in much affliction of mind for her loss, she repaired unto me to know what was become of him; that I told her he was gone for the Barbadoes, and she would hear of him within thirteen days; which, she said, she did.

A second woman made oath, that her husband being wanting two years, she repaired to me for advice: that I told her he was in Ireland, and would be at home such a time; and, said she, he did come home accordingly.

I owned the taking of half a crown for my judgment of the theft; but said, I gave no other judgment, but that the goods would not be recovered, being that was all which was required of me: the party, before that, {169}having been with several astrologers, some affirming she should have her goods again, others gave contrary judgment, which made her come unto me for a final resolution.

At last my enemy began her before-made speech, and, without the least stumbling, pronounced it before the court; which ended, she had some queries put unto her, and then I spoke for myself, and produced my own *Introduction* into court, saying, that I had some years before emitted that book for the benefit of this and other nations; that it was allowed by authority, and had found good acceptance in both universities; that the study of astrology was lawful, and not contradicted by any scripture; that I neither had, or ever did, use any charms, sorceries, or inchantments related in the bill of indictment, &c.

She then related, that she had been several {170}times with me, and that afterwards she could not rest a-nights, but was troubled with bears, lions, and tygers, &c. My counsel was the Recorder Green, who after he had answered all objections, concluded astrology was a lawful art.

'Mistress,' said he, 'what colour was those beasts that you were so terrified with?'

'I never saw any,' said she.
